THE AUTOMOBILE

VOL. XXV NEW YORK—July 6 to December 28, 1911—CHICAGO NOS. 1-26

ACCESSORIES

Acme torsion springs 698
Apco license plate on front axle 245
Auristophone, automobile 165
Ball bearing, H. C. B., a new 375
B-A tire lock 698
Blowouts, cause of 468
Body, shortcomings of the average 182
Brown power pumps 468
B. & S. ball and throttle joint 245
Carbureter, how to study the 261
Chains require attention 144
Convertible body for depot work 348
C. R. G. carbureter 650
Cyclone ventilator shield 512
Disco self-starter 790
Fitting the car to the buyer 537
Gasoline economizer and filter 286
Grease cup, securely attached 286
G. & A. Carbureter, details of 822
Hartford Safety Crank 164
Heel rest 287
Ideal shock-absorber 838
Inner-lining, Auto Tire Inner-Lining Co. 164
Lambert demountable rim 790
Limousine, new single compartment 490
Lock, B-A tire 698
Magneto, coupling to the drive 287
Maher duplex multi-spark plug 560
Manco safety lock 468
Muffler, the Miller 698
Norma bearings 512
Painting bodies, new methods of 304
Perfect window regulator 560
Phelps trouble finder 165
Rapid engine cleaner 698
Rims, Detroit rust-proof demountable 164
Runabout as winter car 861
Security blowout patch 560
handle for tonneau 245
Solderall compound 286
Speedo air valve 650
Springs, acme torsion 698
Star safety starter 560
Start-lite illumination 838
Tire durability 473
sectional emergency 287
Treads, center-studded, detachable, non-skid. 149
Tuto electric horn 468
Wright spark plug 838

ASSOCIATIONS AND CLUBS

Accessory organization grows 688
A. A. A. annual meeting 1013
A. B. of T. committees named, new 641
six new members of 783
A. C. A., President Taft to be guest of 828
Annual meeting S. A. E. at Dayton 22
Big Village Motor Boosters' picnic 326
Chicago dealers' open-house week 438
Coffin addresses British engineers 917
Delaware Club's annual banquet 895
French clubs resume race control 782
Kansas City Motor Car Dealers' Association formed 685
L. I. A. C. banquet 940
to hold contest 915
Maryland Club watches streets 915
M. C. A. clears sporting skies 275
M. C. A.'s most important meeting 235
Manufacturers' Contest Association meets 115
N. A. A. M. members, new 463
Newark Club plans for new home 39
S. A. E. adopts standard solid tires 321
aluminum castings 25
Arthur Ludlow's speech at banquet 27
carbureter division, report of 26
delegates sail for England 781
flywheels, steel, standardization of 24
headquarters in London 733
how, worked at Dayton 22
lock washer sizes, reducing number of 25
long addendum gears 25
magneto standards, discussing 23
oversize piston standards 25
party ready to sail home 965
prepares for active winter 438
sheet metals discussion 23
shows remarkable growth 1147
spark plugs, tolerance of 24
springs division discussion 23
steel flywheels, standardizing 24
tour abroad 549
tourists now on British trip 966
uniform gear shift position 24
visits French factories 1014
visit is gaining 687
Schimpf succeeds Butler 777
T. C. A. scouts arrive at Richmond 828

CAR DESCRIPTIONS

American "30," concerning the 174
Bergdoll adds a forty 1128
Cadillac characteristics, 1912 666
Chase three-thousand pound wagon on market 243
Columbia out with Knight motor 13
Corbin, pertinent details of 354
Electric products, some recent 214
Franklin omits auxiliary exhaust 946
G. J. G. unit power plant a feature 1001
Kissel-Kar, details of the latest 310
Knox adopts long stroke 898
Krit line, few changes in the 1912 1042
Lipman new "Six" makes its debut 205
Locomobile, refinements of 1912 456
Marmon "Thirty-two" 135
Mercer Thirty-five in detail 492
Metz, few changes for 1912 902
Mitchell motor, explaining 810
National construction, details of 534
Overland 1912, four chassis types 714
Pierce-Arrow, 1912 models 452
Premier, Series M 758
Rambler refinements 671
Rapid trucks, simplicity an objective point in 1912 243
Republic car, an Ohio product, the new 242
Selden, refinements for 1912 854
Speedwell, specifications of the 624
Stearns-Knight motor introduced 3
Stevens-Duryea, six-cylinder 216
Stoddard-Dayton at close quarters 317
line, six-cylinder Knight features 314
Warren-Detroit models 254

COMMERCIAL

Armleder enters automobile field 161
British makers, passenger business of, falling off 80
Chicago truck run 476
truck run finished 322
truck run, lessons drawn from 523
truck run, 20 clean scores in 522
Detroit trade booming 482

Locomobile fire wagon for White Plains 204
Longest oil truck 875
Mack-Saurer combine completed 686
Mais Co., new officials 479
Moline factory doubled 479
Motor wagons for military use 809
New electric in the field 43
Patrol wagon, cost of South Bend auto 117
Power wagons, introduction of 689
Pullman builds taxi 482
Relation of engineer to purchaser 35
Reo plans big output 484
San Francisco, new winners on revision 710
Saurer and Mack companies combine 553
-Mack combine completed 686
truck reaches New York 205
Self-starting truck 940
Service cars at Municipal Congress 551
South Bend auto patrol wagon, cost of 117
Transcontinental Packard truck arrives 414
Truck operation, what fuel costs in 90
what it costs to run a 167
Trucks in mail service 918
take place of wagon train 285

CONTESTS

Alco rests on its laurels 460
Amarillo, record crowd at 415
Bedford climb, Flanders stars at 642
Benz, Fairmount winner, Bergdoll in 603
Bergdoll in Benz, Fairmount winner 603
Boston figures on races 371
Brighton Beach two-day meet a success 40
24-hour race announced 413
Beach 24-hour race postponed 115
Beach, two-day meet 370
world's records fall at 384
Buffalo Club run 161
run, seventeen start in 412
Brooklands-Sunbeam test 483
tour, thirty in 370
California tests commercial cars 662
Carbureter makers offer prizes 241
Chalmers owners consistency tour 478
Charter Oak Park meet at Hartford 552
Chicago contest happenings 437
Motor Club Reliability 798
Motor Club, Two-day Reliability 160
run, many clean scores in 778
run, seventeen entries 713
run to be eight-day affair 235
six-day, preparing for 386
truck run 476
truck run finished 322
truck run, lessons drawn from 523
truck run, seven still perfect 280
truck run, 20 clean scores in 522
Cincinnati climb, Nationals win at 199
four road races at 280
Cleveland reliability starts in heavy rain 118
run, clean scores in 160
Colby star performer at Omaha 638
Columbus to see 200-mile race 280
200-mile, Westcott wins 413
winner to have fine cup 365
Commercial cars, California tests 662
Danbury meet, bad weather kills 642
Dead Horse climb, arrangements completed for 79
hill climb, August 12 199
climb next 239
Denver Chalmers owners' consistency tour 437
-New York tour sanctioned 685
reliability a success 686
Desert race, 550-mile across 783
Detroit conducts sociability run 665
Dirt tracks, fate of in balance 37
Elgin, all eyes turn toward 294
races, big fields in 198
races, progress shown in 363
clans gather for 284
races, seventeen entries so far for 117
stock races, records fall at 333
Endurance, American wins long run 755
Evansville Club stages climb 1018
Fairmount, money lost on 749
Park race 478
Park race, blanks out for 324
Park race, preparing for 552
Park race, Quakers in row with Mayor over 116
Quaers ask for Fairmount date 1149
race, protest against 1079
winner, Bergdoll in Benz 603

Farmers' sociability run 414
Fern Bank, Cole and Fiat feature 432
good fields in 370
Flanders cars break records 853
French Glidden, Fords in 782
Grand Prix, entries for 852
Grand Prix, entries in the 1912 French 1149
Grand Prix, Fiat wins 160
Grand Prix, reflections of the 202
Gaillon hill climb 664
Galveston, fast racing at 236
Gearhart Beach, small fields at 414
Georgia State tour has 50 entries 919
tour a hard ride 1016
tour a success 940
Georgians to tour State and see races 525
Glidden changes, ask for 411
eleven entries for 161
fourteen clean scores in 750
has 50 entries 505
has 61 entries 552
only stock cars in 370
only two teams perfect in 651
pathfinder en route South 438
score enter 327
to be good roads tour 205
to be won by team work 241
twenty-three car teams in 641
Grand prize and Vanderbilt races, Savannah gets 115
course under harrow 238
Fiat Bruce-Brown wins 979
looms in near prospect 756
Grand Prix, boycott for 1912 French 1079
rules for the French 1078
Guttenberg races 158
races to be run July 22 115
Hamline, fast time at 435
Harrisburg, Hudson & Cadillac win 853
Hartford to have road meet 370
races 484
races, rain kills 437
Hughes makes explanation 239
Indianapolis race, date set for 783
Kansas City, see Pickens' hand at 461
Kline-Kars win at York 988
Lake Tabor run, six forfeit in 373
Long Island Club sealed handicap 709
Los Angeles, fast time at 708
races sanctioned 685
Lowell, Vale; Redivivus, Riverhead 79
M. C. A. clears sporting skies 275
defines Grade 4 contests 463
Making motor trucks stay sold 290
Maxwells alone forfeit in Glidden 699
Maxwell scores in Lu-Lu's run 551
Milwaukee Sentinel trophy, Imperial wins 163
Minneapolis, National wins thrice at 827
to hold hill climb 687
Minnesota winners: Marmon; Flanders 203
Missouri A. A. run, five perfect scores in 79
Missouri run, Dorris wins 324
Mont-Ventoux hill climb 281
National breaks world's road mark 660
Newark run, thirty-seven perfect in 796
Old Orchard, fast time at 412
flyers enter 370
meet, program for 319
no records at 431
Oldfield, Lee, held without bail for Syracuse accident 552
Omaha run, Ford wins 479
seventeen starters in 436
Ossining hill climb, National cars sweep card at 38
Ostende meeting, the 437
Park racing, abolish 665
Peoria, world's records broken at 687
Philadelphia reliability abandoned 827
Phoenix, Pope stars at 852
desert race, National wins 826
Pickens' hand at Kansas City, see 461
Point Breeze, fair card at 196
Simplex and Cino win at 520
Port Jefferson climb, National stars at 428
Pottstown, Velie stars at 414
Premierites nearing Pacific 161
Prince Henry tour, awards in 160
Promoters must protect public 479
Quaker City Motor Club contest 159
Race records of A. A. A 941
Racer sues for prize 710
Racing season promises activity, 1912 1079
Racing circuit planned for Middle West 895
put in disrepute by advertising 79
season, resume of 1912 990
Remy Brassard changes hands again 235
successfully defended 279
Salem, good racing at 412
San Antonio, National wins 853
Santa Monica, big entry list for 638
Savannah, big purses offered 734
card filling 825
gets Grand Prize and Vanderbilt races for this year 115
races have 54 entries 873
races, places and show money in 642
speed practice open for 42 cars 892
Scranton, records stand at 415
Sioux City, fatal accident 710
Speedway, new motor 505
Sporting events are stirring 235
Springfield sees races 643
Stanley hill climb 161
St. Louis tour starts West 280
Success crowns Dead Horse climb 267
Syracuse meet 474
fatalities mar 474
run a success 665
track races 437
Ten-mile track mark lowered 158
Time-run, Long Islanders' secret 754
Vanderbilt Cup, Lozier smashes record 932
races, Savannah gets Grand Prize and 115
Virginia sociability run 664
Watson Cup, forty-four in 754
White Plains, Election Day races at 826
Winnipeg motorists, big month for 415
Wisconsin State A. A. run 163
tour, protests winner of 202
Wishart says he will take an appeal 643
Wishart's plea denied by contest board 919
World's records broken at Peoria 687
road mark, National breaks 660

DIGEST OF FOREIGN PAPERS

Aeroplane improvements, no conspicuous in France 767
Bends of road dangerous 767
Casehardening department, on the organization of a 545
work, defects in 628
Celluloid, uninflammable imitation 1135
Change-speed set, new hydraulic 766
Engine efficiency 858
Farm implements, motor driven 1000
Forced-draft radiator 1134
Fused silica for plugs, etc 863
Gangplow, motor 859
Gasoline solidification 863
German construction 814
Hardened steel articles, expansion and contraction in 544
Hydraulic transmissions 998
Ignition, a vigorous 815
Italy, market conditions 955
Knocking, its causes 858
Lock nut, a British improvement 862
Lubricating oil burned smokelessly 863
Magneto timing, automatic 954
Materials for construction 499
Metallic machine parts, rules for preservation of 815
Motor cultivators, harrows and hoes 544
Oxy-gasoline flame for welding 1134
Platinum, substitute for 721
Quality test for finished parts 499
Rain-water drains from tarred roads 767
Renault & Hele, show types 998
Ruthardt magneto, features of 814
Safety cranks 906
Safety starting cranks 772
Tarred roads, rainwater drains from 767
Tools in the motorist's box, useful 629
Water tube joint 863
Wheels of wire and wood 907
Whip as accessory 499
Windshield, wire mesh 815

EDITORIAL

Acessibility, greater, needed 410
Accessible car, the 916
Annual model idea 36

THE CLASS JOURNAL COMPANY

231-241 WEST 39TH STREET

NEW YORK CITY

VOL. XXV. NEW YORK—THURSDAY, JULY 6, 1911—CHICAGO No. 1

THE AUTOMOBILE

Coming of the Silent Motor

What the Market Affords Besides the Poppet Valve

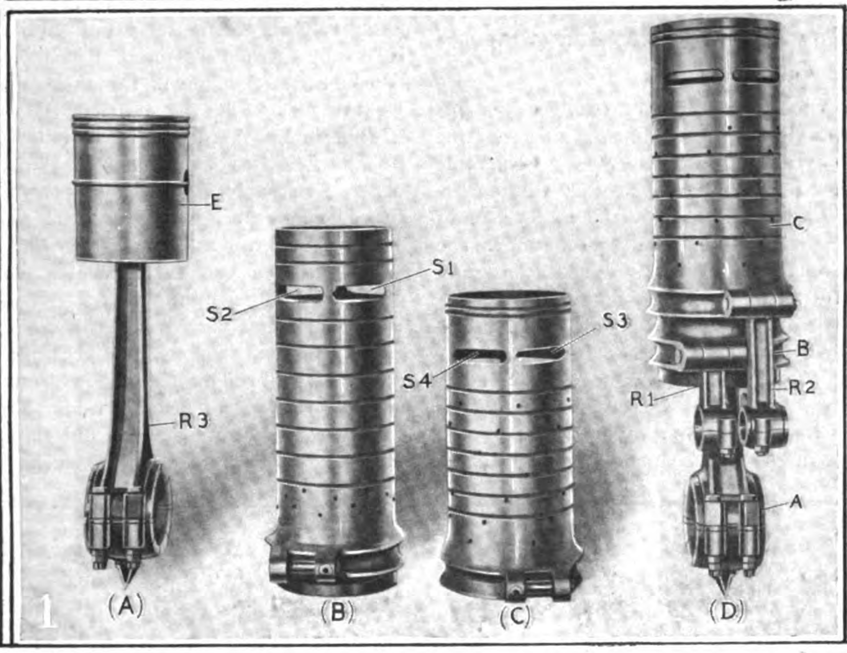

Fig. 1—Presenting the connecting rod assembly of the sleeve type of motor, also the connecting rod with its piston in place, as well as the sleeves after they were taken out of a motor following 6,000 miles of tryout work

Thomas J. Fay, Editor of THE AUTOMOBILE, *presents the first of a series of articles dealing with the problems of motors, with particular reference to other than poppet valve types, taking up the several questions as they are influenced by the conditions of the service in America, relating the causes for the differences in the practices between American and foreign countries, taking advantage of the actual products as they are being made in America to illustrate the points to be emphasized.*

AUTOMOBILISTS in this country have listened to the murmurings of the builders of automobiles in England and on the Continent, and the trend in these quarters has undoubtedly been in the direction of the sleeve type of motor and the silent chain. Coupled with these stars of the automobile world the long stroke design of motor has been a conspicuous factor, but few indeed are the students of automobile designing in this country who were able to account for the lethargy of American designers, if such it was. At all events, the production in this country has been held tenaciously to previously fixed standards, and a careful study of the situation would seem to indicate that the acumen of the American maker has not been dulled by practice in the face of a divergency of experience.

That a fact may be quite apparent to even a man of skill, and yet be difficult to define, is shown by the very delay that is present in the motor situation; and those who have given themselves to the task of understanding these things long ago arrived at the conclusion that a good automobile on a Roman road in France or in England is the veriest junk pile on a dirt road in America. We cannot run cars in this country when the clearance is four inches, nor can we accept the practice of the builder of the type of car that has a four-inch clearance, hampering the same by the mere expedient of changing the camber of the springs to get the extra clearance when it is desired to ship and use this foreign clearance car in places where the roads are substantially unimproved.

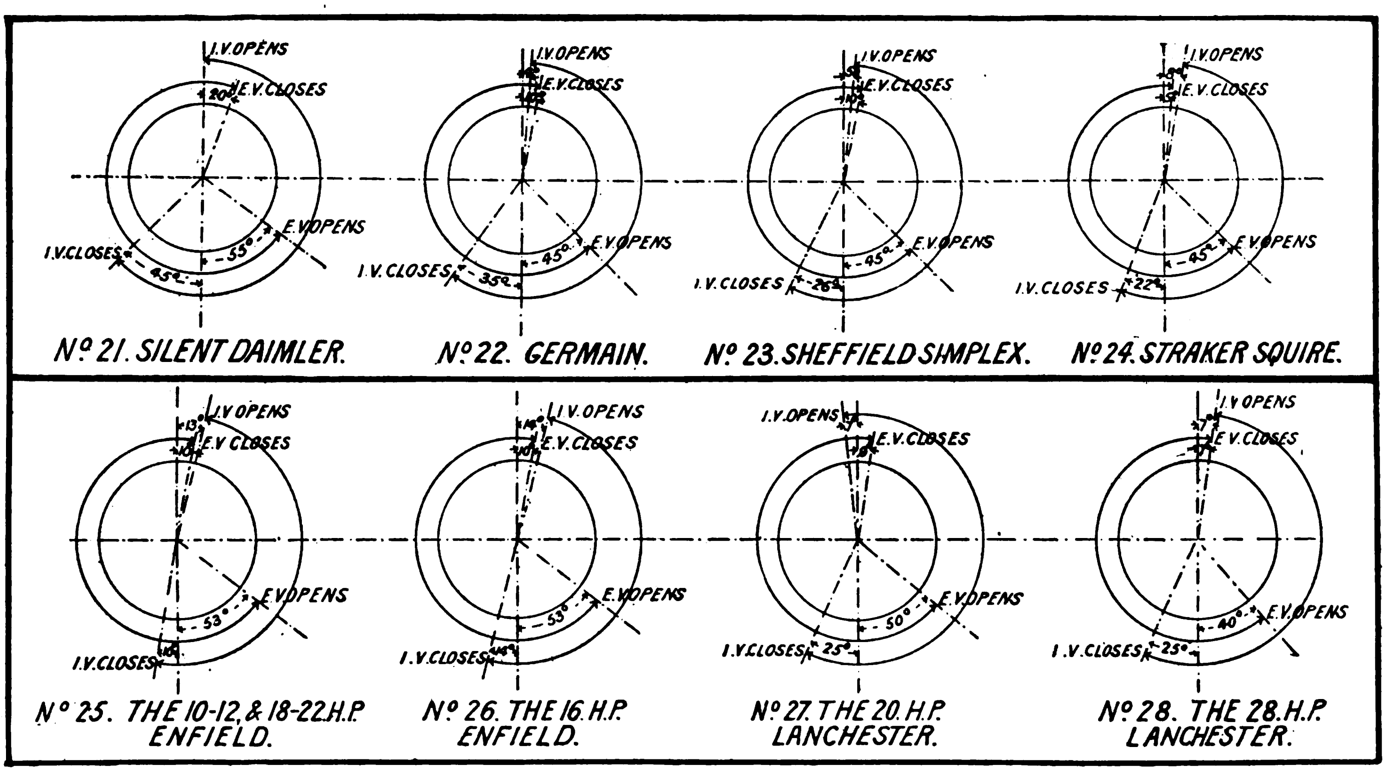
If an automobile is to perform with good satisfaction on unimproved roads it must be designed with special reference to the road condition, and the clearance that must obtain requires a considerable effort on the part of the designer, since he must depart absolutely from foreign practice, and, while holding the center of gravity as low as possible, keep the mass from scattering, and poise the same so that it will not partake of a cranky set of movements in response to speed and road inequalities. It would have been a simple matter for American designers to accept the practice as it comes from overseas and enjoy the good performance of the sleeve types of motors, were there nothing in the rest of the designing problem; but wisdom and experience have had the effect of applying the brake to activities of this character for a sufficient time to permit the designers to revise the chassis characteristics to accord with the new requirement.

It will be impossible to predict the extent to which sleeve and rotary types of valves will be used in automobile motors in the near course of events, but there is ample evidence of the fact that this movement is wide and appearances are in favor of the contention that it has taken on a permanent phase. At all events, the time has arrived when it will be opportune to present the whole subject in a series of articles, rather than to try to cover the matter in a single article at some length, but it is not believed that there should be much more theorizing, nor is it necessary to thus lamely proceed, since examples of the work that is being done may be used to illustrate the points to be made, and for this particular effect the new Stearns-Knight and Columbia-Knight motors will be described and discussed.

Discussion Is Toning Down in the Light of Experiences Gained

Some years ago when Charles Y. Knight brought out his sleeve type of motor in America he was evidently ahead of the state of the art, and he was unable to arouse any considerable measure of interest in this type of motor at that time. Circumstances culminated in the bringing out of the Silent Knight motor in England, and the success of this motor under the direction of the British-Daimler Company was sufficiently marked to attract the attention of such companies as the Panhard in France, Minerva in Belgium, Mercedes in Germany, and the company of the same name in Austria. The earlier negotiations on the part of Mr. Knight with the makers of automobiles in America made it somewhat uncertain as to which of the companies would adopt this motor, and we understand that the Knight contract with the above named foreign makers of automobiles is such that his right to license American companies is limited to four concerns. We are unable at this time to enter into a description of the Knight type of motor as it will be used in more than two of these companies, and the descriptive matter hereinafter is confined to the Stearns-Knight motor and the Columbia-Knight motor, and we regret to state that the information given in relation to the Columbia-Knight motor is somewhat less complete than is our wont, due to the fact that the Columbia-Knight car is going through long and continued road tests, so that it has been impossible to get photographs of such of the details as would seem to lend interest to this discussion, so that right is reserved to go into the matter of details at some length at a propitious time.

There will undoubtedly be a great deal of discussion in relation to the sleeve type of motor versus poppet valve types of motors, and users of automobiles may have some difficulty in arriving at a proper conclusion of the position that they ought to take relative to these types of motors. But users of automobiles can well afford to take into account a plurality of considerations; for instance, in the preparation of material that will be used in the further discussion of motors in articles that we propose to run, discovery has been made of 54 designs of motors, other than poppet valve types, that have been worked upon and are being tried out with more or less satisfaction. It is not the purpose here to either suggest or advocate that comparisons be made in the absence of authenticated data, and we are struck by the fairness of the attitude of Charles Y. Knight in his discussion at various times relating to the merit of the sleeve type of motor as it compares with motors of other generic types. Quoting from Mr. Knight's paper entitled "The Valveless Engine" in a paper read before the Royal Automobile Club as far back as October 15, 1908, Mr. Knight said: "It was not valve trouble which inspired me with the desire to build a motor different from the then accepted type." From this statement it will be seen that the inventor had no grievance against poppet valve types of motors of the character that is brought to bear in promiscuous discussion, and we will have to look further in Mr. Knight's presentation of his matter to find out what he did think. In this connection the inventor went on to say, "I struck out boldly along new lines



Selection from a series of timing diagrams that appeared in the Motor Car Journal, showing the settings of the intake and exhaust valves of several different makes of motors, including a Knight motor

for the very good reason that close association of over 20 years with mechanical matters taught me that a novice in any special field had little chance of improving upon an accepted design. I clearly made up my mind, if possible, to produce an internal combustion motor different from anything which had yet been constructed." It will be seen from this statement that Mr. Knight's initial interest in the matter had the same impetus as that which induced hundreds of inventors in many lands to build automobile motors, and, like his confreres in the same zone of activities, he had to take his chances with the rest and follow the bent of an inventor's inspiration, buoyed up by the enthusiasm of which genius always has a surfeit.

In putting the matter up to the British-Daimler Company, Mr. Knight relates the attending circumstances in language as follows: "We did not bring to the Daimler Company an untried proposition. We brought a practical although not refined product—a motor which had already withstood the test of public use for two years, and came through with clear records, numerous drastic tests in public competitions with the best motors of the other types." In pronouncing on the question of power, Mr. Knight states: "The only feature regarding which we made no representations to the Daimler management was the matter of power as compared with the other types, as conditions under which tests are made in different establishments vary to such a degree that even now I place little credence upon what I read regarding the performance of any motor under tests in its own works."

Early History of the Knight Motor Building Effort

In recounting his adventures Mr. Knight stated in his paper of October 15, 1908: "Experimental work began upon this motor five years ago last August. The first model was 3 1-2 by 4 inches, single cylinder horizontal. It was operated successfully through the use of but one sleeve, but the gear necessary to give it the proper motion was too complicated to be quiet, and this construction later gave way to two sleeves driven from an eccentric shaft. We experimented one whole Winter in the shop before any effort was made to design a practical motor for car use, and when this motor was finally undertaken during the winter of 1904, the result was a four-cylinder engine, 3 1-2 inches bore by 4 inches stroke. This motor was finished in October of 1904 and put into a Panhard type car which I had driven for two years. This motor is running to-day in the self-same car. I drove it about 4,000 miles that winter and about 8,000 miles the next season.

"We designed and constructed our first experimental car in the Spring of 1905, this being equipped with a four-cylinder 4-inch by 4 3-4-inch motor, with practically no change in design. This car is in service to-day."

A side light upon the activities of the inventor in this case will suffice to indicate something of the vicissitudes that beset the path of the soldier of fortune and the man who wants to bring out something new, and Mr. Knight's own language will best bring out the point that is here to be made: "I have no doubt that had I come into contact at that time with some of the critical experts whom it has been my good fortune since to meet I should have been dissuaded from spending a dollar upon the idea, yet, in the light of recent startling mechanical and scientific developments, I have almost reached a state of mind when I hesitate to entertain or express doubts regarding the possibilities of any reported accomplishment. * * * Frank Munsey, one of the world's most successful publishers, in a treatise on the subject of 'Schemes' for increasing the volume of business, said: 'If you have an idea and have confidence in yourself go ahead and work it out. It's all well and good to look around and see just what is the condition of the channel ahead of you, but if you have any hope of being successful don't by any means call in a dozen advisers and discuss your scheme with them. The best idea that was ever born can be talked to death around a council table. If you expect to devise anything that does not involve some risk you are smarter than the average smart man. If you have an idea and have confidence in yourself it is up to you to grasp the situation vigorously and surmount the obstacles. Counsellors will undoubtedly point out stumbling blocks. It is for you to get over these. Any man can do an easy thing. Ability means the power to do things other people think cannot be done or fear to undertake.'" In thus taking serious notice of the rather good advice from the trenchant pen of Frank Munsey and emulating the idea in practice under what must have been a difficult set of conditions, Mr. Knight has been good enough to indicate one of the reasons why he reached the goal of success, and this may be the precise ground that other inventors take in the struggle that is now going on, nor can we tell at this time how many individual efforts are being given the force of persistent attention, excepting that we have been able to find 54 examples outside of the poppet-valve field.

Stearns-Knight Motor Introduced

Chassis Revised to Assume New Responsibility

A discussion of the new Stearns-Knight motor, presenting reproductions of working drawings of the chassis, and halftone reproductions from photographs of the motor after it was operated in a car for about 6,000 miles and taken apart under the direction of the author for the purpose of observing the conditions for lubrication, showing the condition of bearing surfaces of the sleeves and other functioning parts of the motor. From the power point of view a Prony brake test is given of the new Stearns-Knight motor, and a second Prony brake test is offered showing the power and characteristic of the Stearns poppet valve type of motor, the idea being to bring out the difference in the service characteristics of the two types of motors and to show wherein the Stearns-Knight motor differs from the earlier effort.

REMEMBERING that there will be ample opportunity on the part of the patrons of the automobile industry to gather such information as may be had in the course of mere discussion bearing upon the features of sleeve types of motors, it seemed to be in keeping with the situation to examine into the performance of the new Stearns-Knight motor as it is made in the plant of the F. B. Stearns Company, Cleveland, Ohio, and to compare the details of actual road performance with the motor characteristic, observing in the meantime the extent of agreement. In the road tests it was found that the motor throttled down under hill-climbing conditions and accelerated on a grade satisfactorily even with a fixed spark advance, and that the motor presents a wide range of stability despite an indifferent attempt at timing the spark. It will be remembered that the timing of the Knight motor is a matter that the designer is permitted to fix upon much in the same way that poppet valve types of motors are timed, and the diagram given below shows the preferred timing as fixed upon by Charles Y. Knight in his effort on behalf of the British-Daimler Company compared with accepted timings of good makes of poppet valve types of motors, and it will be seen that the Knight timing is as follows: The inlet port is timed to open on the top dead center and to close 45 degrees up on the compression stroke. The exhaust port opens (early) 55 degrees before the end of the firing stroke, and closes (late) 20 degrees down on the suction stroke.

Referring to the curves of motor performances as shown in Fig. M of the Stearns-Knight motor as compared with Fig. N of the Stearns poppet valve type of motor, it will be at once apparent that the torque characteristic of the Knight type of motor is at wide variance with the torque characteristic of the Stearns poppet valve type of motor. A mere examination of the torque curve of the Stearns-Knight motor would suffice to show that it is an easy motor to crank, and actual experience with the motor bears out this surmise. In the face of "soft" cranking, which would indicate poor compression in a poppet valve type of motor, the actual torque at low speed is relatively high, and it is an advantageous fact that this torque increases with increasing speed for a large part of the range, and recedes but slowly thereafter up to 2300 revolutions per minute.

What Investigation Shows in Relation to the Performance of American-made Sleeve Types of Motors

Referring to the illustration (Fig. 1) of the Stearns-Knight motor construction, (A) shows the piston and connecting rod, (B) is of the inner sleeve, (C) presents the outer sleeve and (D) is an assembly of the connecting rod A with the inner sleeve B and the outer sleeve C in the concentric relation with the piston E just as they go in a cylinder of the motor. These sleeves are reciprocated by means of connecting rods R1 for the inner sleeve and R2 for the outer sleeve, and they are actuated by an eccentric shaft S1 in Fig. 7, whereas the piston attached to its connecting rod R3 is actuated by the crankshaft C1 in Fig. 7. The group as shown in Fig. 1 supplemented by the crankshaft and eccentric shaft as presented in Fig. 7, constitute the functioning mechanisms in the Stearns-Knight type of motor in substitution of poppet valve mechanisms of former practice. Instead of actuating poppet valves for the purpose of controlling the mixture and the exhaust, the sleeves B and C in the concentric relation with the reciprocating piston move on each other so that the slots S1 and S2 in the sleeve B register with the slots S3 and S4 in the sleeve C in registry with transfer ports in the cylinder proper, according to the most approved four-cycle timing of a motor, thus doing the work as it is required in the performance of the motor according to the Otto cycle.

By referring to Fig. 6 it will be seen how the sleeves (B) and (C) fit in the bores of the cylinder (A), and the transfer ports P1 and P2 as they show in this pair of cylinders are so placed as to register with the slots S1 and S2 of the concentrically related sleeves (B) and (C) when they are nested in the cylinder, of which there are four in this motor, for the intended purpose.

The Piston Is Flattened on Two Diameters in the Plane of Minimum Pressure for the Purpose of Working the Motor with Low Clearance.

Fig. 2 shows a pair of the cylinders as they were photographed in place on the motor as it was taken down by the writer after the automobile in which it was mounted had traveled approximately 6,000 miles, and in view of the fact that the photographs were taken by a most excellent camera under particularly favorable conditions, the reader is enabled to judge of the conditions of lubrication that must have obtained during the entire performance of the motor, as indicated by the highly polished surfaces at every point, with entire absence of scoring or other blemishes such as would be present were the lubrication faulty and the motor made to serve for so long a time in a "try-out." Referring to Fig. 2 in the cylinder S1, the surfaces that come into view are of the cylinder wall proper, whereas the surface S2 is that of the offset of the cylinder, and the surface S3 is the inner surface of the short sleeve as shown in (C) in Fig. 1, bringing the edge of the long sleeve S4 into view. The holding bolts B1, B2, B3, B4, B5, and B6, for each cylinder, are used to hold the cylinder heads as they are shown in Fig. 5 in place; and referring to this latter figure the junk rings R1, R2, R3 and R4 are clearly indicated above auxiliary rings R5, R6, R7 and R8. The junk rings and the auxiliary rings above them bear against the inner surfaces of the long sleeves maintaining tightness between the junk ring assembled in the head of the motor and the bore in which the piston reciprocates, thus preventing compression from leaking around the tops of the rings or through the openings in the sleeve, it being the case that the junk ring is so wide that it covers the sleeve ports, including a considerable overlap for the obvious purpose. The illustrations of the four cylinder heads H1, H2, H3 and H4 in Fig. 5 having been reproduced from photographs of the actual cylinder heads as they were taken out of the motor by the author, show the effect of the long service test to which the motor was subjected, and the junk rings clearly indicate that the surfaces all over were highly polished and that the conditions of lubrication were particularly good. The cylinder heads have cavities C1, C2, C3 and C4 forming the combustion chamber proper, and the spark plugs S1 shown in the head H3 protrude through the depressed heads into the hottest part of the combustion chamber, where they are in the flush position, and the thermic conditions obtaining are somewhat indicated from the fact that the growth of a carbon deposit is only barely indicated at G1 in the head H1, at G2 in the head H2, and G3 in the head H4, it being the case that the head H3 is tilted so that the cavity does not come into view, but the author is able to state that the coat of carbon residing therein was in no greater presence than that shown in the examples that are here to be seen.

The two cylinders as presented in Fig. 2 were the third and fourth of the motor lying next to the dashboard in the car. The two front cylinders were removed and were photographed, as shown in Fig. 6, alongside of one of the pairs of sleeves. Referring to Fig. 10, the front end of the motor with the front pair of cylinders removed is brought into view, and the sleeves of cylinder No. 1 were then removed, allowing the piston P1 to be seen, showing the piston rings R1, R2 and R3 above the piston pin, and the piston ring R4 in the plane of the piston pin, all of them in a highly polished state, showing every evidence of good lubrication and a tight performance. The piston head H1 shows a slight growth of carbon G1 in the bowl, and attention is called to the fact that the piston head is depressed, forming a segment of a sphere, the idea being to properly regulate the compression ratio, remembering that the head is inverted and fills some of the space in the bore; but there is a further object in depressing the piston head, the portent of which is enough to dictate this shaping, it being the case that a layer of gas fills the depression so formed and shields the metal of the piston head from the hot glare of the burning gas, thus eliminating a very serious thermic trouble in motor work.

The second cylinder as shown in Fig. 10 was photographed with the sleeves S1 and S2 in place, and attention is called to the bright surfaces S3 and S4 around the port P2, thus indicating that a tight relation obtains, and it may be proper to say here that the presence of carbon at the lips of the ports has proven to be a boon rather than a detriment, due to the fact that the carbon and the lubricating oil are mixed and ground into an infinitely fine state, and the latter fills in the interstices, if such there are, leveling off the surfaces, perpetuating the condition of good performance, and this is probably one of the reasons why the Knight type of motor performs so very much better after a considerable period of service than it does when it is brand-new. In the investigation of the carbon deposit question for the purpose of finding out whether or not the sleeve type of motor would be clogged up by carbon deposits, a series of little grooves cut with a diamond-pointed tool were made on each side of one of the ports of a sleeve, and the examination of this roughened zone in the proximity of the lips of the ports after a considerable service showed that the grooves had completely filled up with a prime carbon paste, and that the leakage which might have been induced originally by the roughening of the surfaces in this critical zone had departed entirely, and the motor performed quite as satisfactorily as if the sleeves had been left in their original polished condition. From this and other evidence it would seem that the original claims for the Knight type of motor, which had for their foundation the idea that the motor improved with service, are based upon the beneficial action that takes place when fine carbon dust is mixed with lubricating oil and rubbed into the surfaces of the metal. There is a great difference between forming a scale out of carbon, silicon and other substances and allowing it to deposit over the heated surfaces of the combustion chamber and the manufacture of a carbon paste, rubbing it into the pores of the metal as fast as it is formed, which is the action that takes place in the sleeve type of motor. In a word, the formation of carbon is beneficial to the motor, in that it manufactures graphite, which is known to be an efficacious lubricant, and as fast as this lubricant is manufactured it is taken up between the rubbing surfaces of the sleeves, and while it is being ground into an intimate mixture it is being rubbed into the pores of the metal, filling the interstices at every point and producing surfaces that are mirror-like in every particular.

Having Examined the Surfaces of the Sleeves from Photographs Taken from a Motor That Had Done Long Service It Remains to Study the Working Drawings and Observe of the Things That Were Done to Harmonize this Type of Motor in a Chassis That Has Proven Its Worth Under American Road Conditions

Referring to illustration C, which is a section of the motor through a cylinder, it will be seen how the long sleeve S1 serves as the bore for the piston P1, and how the short sleeve S2 is sandwiched between the long sleeve S1 and the cylinder wall W1. It will also be seen how the cylinder head H1 is flanged over at F1, fitting the cylinder proper, making room for the sleeves S1 and S2 between the bore of the cylinder in the head and the inserted part of the cylinder head H1, allowing also the space for the junk ring J1, which serves to cover the ports P2 in the outer sleeve and P3 in the inner sleeve, and with the sleeves in the position as shown the exhaust ports P4 in the outer sleeve and P5 in the inner sleeve are also covered by the overlapping of the sleeves under the conditions as observed, so that the combustion chamber is tight against compression, and any leakage possible to consider must pass by the junk ring J1, bleed across the lip surfaces and then negotiate the bearing faces between the sleeves. A study of the section of the motor in the vicinity of the ports will suffice to show that tightness against the leakage of compression is a condition that improves with service, due to the fact that the surfaces are slowly but surely undergoing a process of polishing. Moreover, the lubricating oil as it is sucked up between the sleeves has such a large surface to cling to, remembering that it has a high surface tension, produces a self-packing condition that is not to be overcome by any pressure that can be brought to bear, and the action that takes place under working conditions brings about the shearing of the lubricant in its section, so that the actual work done is within the molecular structure of the lubricating oil. It is impossible to consider that there is any metal-to-metal contact of the sleeves and the cylinder walls, and the polishing effect that is indicated by continued service is at such a slow rate that over 5,000 miles of travel of an automobile on the road under the impetus of this motor is barely sufficient to remove the evidences of grinding of the sleeves, in the face of the fact that the grinding work was done with scrupulous care.

Great Care Is Taken to Cool All of the Flame-Swept Surfaces by Carefully Directing the Flow of the Cooling Water

Referring again to Fig. C, it will be seen how the cylinders and heads are water-jacketed, and the baffle plates (not shown) direct the flow of the cooling water in a spiral sheet, sweeping over all of the surfaces, allowing the same to leave at the highest point, entering the water outlet at the top, traversing the length of the water manifold to the receiving point in the radiator. The extremely high mean effective pressure that is shown in this motor is partly accounted for by the liberal area of the inlet and exhaust ports, but a study of the motor performance goes to show that this accounting is insufficient, since the motor characteristic is markedly different from that which obtains in motors that have poppet valves of large areas with a timing the same as that which is employed in this particular motor. It has been suggested that the high mean pressure realized is in a large measure due to cold lips of the parts brought about by the precision with which a liberal supply of cooling water is permitted to brush the surfaces in juxtaposition to the lips of the ports, thus maintaining a constant low temperature. In the shaping of the inlet passageway, as it approaches the ports, it will be seen how the grade is sloping in the direction of the combustion chamber with entire freedom from "baffles," and it is pointed out that in this detail the Stearns-Knight type of motor differs materially from the earlier Knight designs, it having been found that this sloping of the gradient prevents the accumulation of liquid fuel and adds materially to the smoothness of performance of the motor, but it is to be regretted that this section illustration does not show that the hydraulic grade is in the direction of the carbureter rather than in the direction of the combustion chamber of the motor for the major portion of the distance, the divide coming in the transfer port as it approaches the combustion chamber of the motor. An examination of the exhaust port, as compared with the inlet port, shows a distinct difference in detail, for instead of a smooth approach, as required on the inlet side, the lip curls up and the exhaust gas after it passes out is permitted to expand, and it would seem from what has been observed that the compact screen of gas remains in its compact state until it gets by the port, after which it swells, maintaining a certain intimacy, and it departs by way of the exhaust manifold as a body, thus leaving behind a certain excellence of the state of scavenging that has not been experienced heretofore.

In the design and construction of the sleeves S1 and S2 as shown in Fig. C care has been taken to thicken the walls at W2 for the long sleeve and W3 for the short sleeve for the purpose of adequately resisting the work that they have to do in the interpretation of the reciprocating motion as it is delivered to the sleeve by the connecting rods R1 for the long sleeve and R2 for the short sleeve, as delivered through the good office of the eccentric shaft E1. The bosses to which the connecting rod pins relate are joined to the sleeve through the section of metal formed with a pair of parallel ribs running around the girth at the extremities of the sleeves. The fact that the sleeves are given their reciprocating motion by means of connecting rods, actuated by an eccentric, imparting the motion to one diameter of the sleeves, has been commented upon as indicating diagonal loading and a tendency to induce a lateral thrust, corresponding to a diagonal characteristic, but it is feared that those who gave this matter the benefit of their distinguished consideration were too busy to construct a diagonal of the forces, and they therefore failed to penetrate sufficiently into the intricacies of the problem to permit them to arrive at the conclusion that the lateral pressure is merely nominal, due to the fact that the sleeves are of great length as compared with diameter, so that the diagonal of the forces, when expressed in pounds per square inch on the projected area of the sleeves, is resolved into a mere decimal of a unit.

The water pump W4 is of the centrifugal paddle type, and the intake I1 passes in the horizontal plane from the under side of

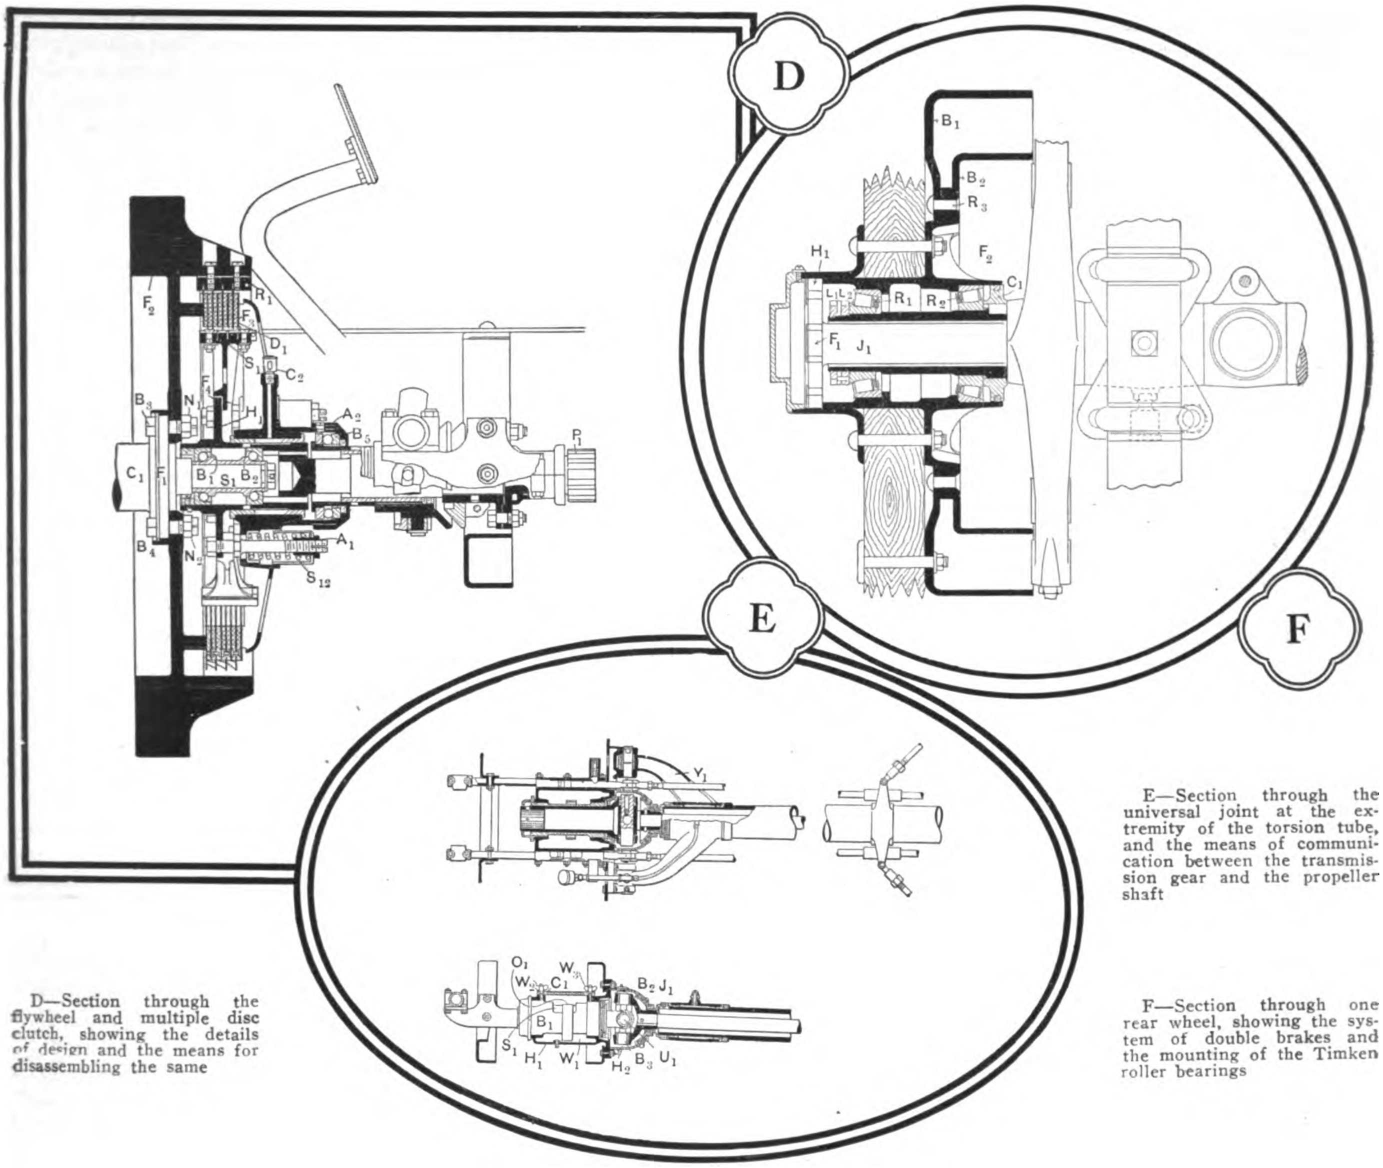
the radiator with an upward sweep at the back of the pump to the axis of rotation thereof. The pump has a flange connection at F2 and a packed screw joint at J2 for the outlet. The capacity of the pump has been fixed with particular reference to the performing characteristics of the sleeve type of motor, and one of the most marked characteristics of this motor is indicated by the use of a comparatively small radiator, suggesting that heat loss to the water jacket is relatively a limited quantity, to account for which requires that a further study of the design of the motor be indulged in. When it was at first suggested that a pair of sliding sleeves be placed in concentric relation with the piston in the cylinder of a motor, the state of the art was such that the experts of that time were fearful of the result. They were unable to see wherein a plurality of joints between the flame and the water-jacketed metal could be turned to advantage, and they were wont to point out that the heat absorbed by the sleeves would pile up in the sections thereof, and an over-heated motor would be the result. Chagrin must have been their lot, for in all truth this sleeve type of motor is remarkable for its cold performance, and come to think of it, the elements for cold performance are all present, and now that the proof of this happy characteristic is in ample presence, it requires no great knowledge on the part of anyone to point to the fact. It has long been understood by those who are intimate with motor designing that the only reason why water is used for cooling is because the heat that gets into the section of the cylinder wall must be coaxed out again, and this is another way for saying that if we can keep the heat from getting into the cylinder wall, to whatever extent this is done, cooling may be dispensed with. That the thinness of the sleeves contributes largely to the good performance is now appreciated, it being the case that there is no difficulty involved in the cooling problem when the walls are thin, since it is in thick walls that heat piles up and resists tapping away. In the further discussion of the thermic relations as they obtain in this motor it will be well to observe that the sunken head, with its water jacketing, shields the sleeves from the fierce glare of the burning gas, and by the time that the piston recedes under the force of the pressure wave the heat wave has fallen to a level that is well within control under the conditions as they obtain in this example. The high mean effective pressure of this type of motor is in a considerable measure accounted for by the influence of the sleeves on the retention of heat, and we may conclude by saying that the fact that a very small radiator suffices for every need is a staunch argument in favor of high mean effective pressure, economy of gasoline consumption, flexibility in the range of performance of the motor, a high co-efficient of stability, resulting in accentuated hill-climbing ability, excellence of the average road performance, absence of noise or knocking, and carrying this idea to the point of throttling the motor to a standstill on a steep grade results in the power dying out without any bucking or other signs of distress.

In the operation of the motor it is the plan to work the ac-



D—Section through the flywheel and multiple disc clutch, showing the details of design and the means for disassembling the same

F—Section through one rear wheel, showing the system of double brakes and the mounting of the Timken roller bearings

celerator for the control of the air and to maintain the spark at the proper position of advance for the most economical result, but it is a noteworthy fact in practice that the motor may be run fast or slow undei a variety of conditions of the load imposed with the spark fixed, changing speed by altering the air that is admitted to the carbureter, thus showing that the thermic conditions are on a stable basis. The possibilities in the matter of the control of the motor may be seen by making a study of the chart Fig. M, in which it will be seen that the torque curve takes a pronounced upward trend as the speed is increased, thus indicating that the range of stability has been advanced, and it looks, comparing this chart with the conditions as they are indicated in Fig. N, as if the range of stable performance of the Stearns-Knight motor has been advanced by a measure that is not far from 500 revolutions per minute. It is by no means certain that there has been any sacrifice of performance at the lower range of speeds to get this better performance at the higher speed, and the excellence of the work that the motor does on low speed on a long steep grade is the best foundation for this belief. This same characteristic is of much advantage when the road is heavy and the motor is required to deliver maximum power at the low range of speed for a considerable period of time.

In the lubrication of the motor the connecting rods are provided with buckets B1 and B2, there being one on each large end, dipping into tilting troughs B2, swiveling on trunions T1, actuated by levers L1 through cam rollers C1 engaging cams C2, which in turn are actuated by levers L2, of which there is one for each tilting oiler. The motion for the control of the tilting oiling system is imparted by the manipulation of a master lever, which may be placed at any convenient point, as on the dash. It has been found in practice that this method of oiling permits the operator to alter the rate of lubrication fo suit the exigencies of service, and to save a motor from smoking when it is doing mild service in town, which is an important matter in these days when the police regulations everywhere cast doubt upon the expediency of generating smoke in the public streets. The gasoline is fed by pressure to the carbureter and thence to the motor, and the pressure in this particular motor is maintained at one pound per square inch through the good office of a piston P6, which plays in a little air cylinder C2 bolted on the face of the crankcase in the vicinity of the eccentric shaft, and motion is imparted to the piston P6 by a connecting rod C3, which in turn takes its motion from an extension of the connecting rod R1 of the long sleeve S1. The little piston P6 in the air cylinder C2 uncovers a port P7 to admit air, and as the piston travels in the direction of the head after it covers this port the air is compressed when it passes by a check valve V1 into a pipe P8, thence to the gasoline tank, but a pressure gauge is placed on the dash for the purpose of showing the extent of the pressure and indicating to the operator of the car that all is well.

Before departing from the cross-section Fig. C it will be to the

point to call attention to the method of fastening the lower half of the crankcase to its mate by means of long bolts B4 and B5, of which there are six, the arrangement being such that the lower half may be dropped down if the knurled holding nuts N1 and N2 for each holding bolt are unscrewed, but in order that this plan may be carried to a successful issue the connections for the lubricating system are so contrived that the joints are automatically made or broken, so that the operator is permitted to get at the working parts of the motor without having to consider the breaking of these joints, notwithstanding the fact that all of the lubricating piping is within the crankcase, and the oil is circulated through piping that passes from the lower to the upper half.

How the Rotative Members of the Motor Are Arranged and Related to Each Other

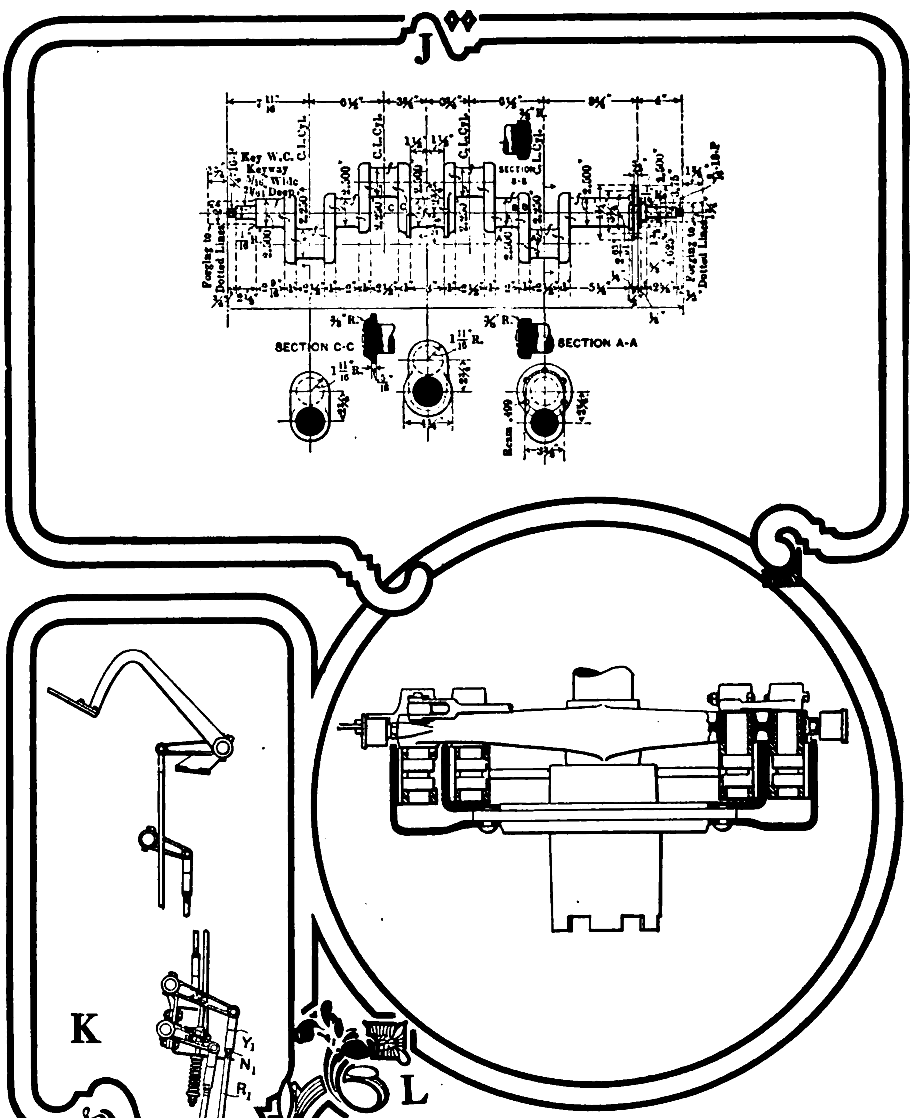
Referring to Fig. G of the assembly of the rotative members, it will be seen how the crankshaft C1 rotates in five main bearings B1, B2, B3, B4 and B5, and Fig. J is a working drawing of this crankshaft giving the dimensions, and attention is called to the fact that the crankshaft is of unusually stout construction with a 5 1-4 inch by 2 1-4 inch main bearing adjacent to the flywheel, while the other main bearings are graded off to 3 inches by 2 1-2 inches at the middle, 2 9-16 by 2 1-2 at the front end, and 2 inches by 2 1-2 inches for the intermediate bearing. The connecting rod bearings are 2 1-2 by 2 1-4 inches, and the cheeks of the throws are 1 inch thick by 3 3-8 inches the other way, excepting that the cheeks facing the midship bearings are flanged out to 4 1-4 inches, it being the case that thrust is taken by this bearing only, and the faces are made considerably wider for the purpose of resisting this thrust. What the detailed drawing shows is that the unusually large torquing moment of this type of motor demands particular treatment, and in addition to placing a bearing on each side of each throw the strength of the crankshaft has been enormously increased not only by using a liberal supply of metal under well-directed conditions, but in the selection and use of specification nickel steel as well.

Referring back to Fig. G it will be seen how the eccentric shaft E1 takes its drive by means of a silent chain from the pinion P1 to the gear G1, and the drive for the auxiliary shaft S1 is through a silent chain from the gear G2 to the other half of the pinion P1. The shaft S1 drives the water pump W1, the shaft passing through, and the magneto M1 is driven by the same shaft with a coupling C2 interposed. The radiator R1 rests upon a fitting F1, and the piping leads from the under side of the radiator to the entering orifice O1 of the pump. The drive for the fan is by means of a shaft S11 in a lubricated plain bearing, with an oil well W2, the source of power being the auxiliary shaft S1 with a belt transmission. The eccentric shaft is provided with a plain bearing on each side of each throw, and a further study of this assembly layout lends substance to the impression that great rigidity is aimed at. At the right-hand side of the layout a vertical shaft V1 reaches down to drive the oil pump O2, the latter being of the gear type, but it differs from oil pumps in general in that the two gears are of dissimilar sizes, the smaller of which is on the end of the vertical shaft, and the large gear serves as a magazine, taking the oil into the housing, delivering it through a circular path to the cored hole H1 within the gear, and there being a plurality of delivery orifices around the web of the gear, oil is delivered to the pipe P2 at timed intervals according to the registry of the holes in the web of the gear. It was found in the course of the experiments that even a ball bearing in the fan drive was too noisy to tolerate, and a plain bearing with automatic means for lubrication had to be substituted instead.

From the motor to the clutch, nested in the flywheel as shown at Fig. D, is the course of the torquing increment of the power on its way to the live rear axle, and referring to this clutch it will be seen how it is assembled on ball bearings B1 and B2 on the stub S1 of the crankshaft C1, back of the flange F1, to which the flywheel F2 is bolted by means of bolts B3 and B4 with locking nuts N1 and N2 to maintain tightness. The clutch is of the multiple disc type, with fabric facings F3 on the metal discs D1, and the drive is through the ring R1, interrupted by the discs as referred to, to the spider S11, which is flanged at F4 to the housing H1, and pressure is exerted on the discs by springs S12 with adjustments A1, by means of which tension may be varied to suit the exigencies of service. The reaction of the clutch spring is taken care of by the thrust bearing B5, which is also provided with an adjustment A2. Lubrication is handled through the cup C2. One of the important points that this design contemplates is the getting at of the clutch in service, and a study of this section will show that there is compensation sufficient to permit of the removal of the pinion P1, thus freeing it from its mate in a way that will be clear to the reader if he will examine Fig. E of the universal joint in the plane of the yoke Y1, showing how the drive is brought about from the clutch shaft to the joint and thence to the propeller shaft, the latter being in the concentric relation with the torsion tube.

The transmission gear of the three-speed selective type is suspended on the live rear axle, thus composing a part of this unit, and the details of design may best be studied by examining Figs. E and B at the same time. In Fig. E it will be seen that the long bearing B1 is in a housing H1 with an oil well W1 and a ring oiler O1, which is placed to pick up the oil in the reservoir and deliver it on top of the shaft S1. There is a cover C1 over this bearing with wing nuts W2 and W3, which may be backed off at will, thus permitting the operator to gain access to the bearing. The universal joint U1 has large bearings B2 and B3 at the trunnions, and lubricating grease is kept within the universal joint by the retaining ability of the housing H2, which is of spherical conformation with a grease-tight joint J1 between the relating members.

Referring to Fig. B it will be seen that the propeller shaft S1 is supported by annular type ball bearings B1 and B2, and that thrust is taken by the thrust bearing T1. Direct drive is brought about through engaging jaws J1, and the stub shaft is supported by an inserted annular type ball bearing B3, while the thrust of engagement is taken on the thrust bearing T2. The sliding shaft S2 is splined, and the sliding gears G1 and G2 are placed thereon. The lay shaft S3 is in the vertical plane under the prime shaft, and the gears G3, G4 and G5 are put on with splines with a separating tube holding them to their proper centers. The reverse gearset R1, given in a separate sketch, and the bevel drive, with the pinion P1 meshing with the gear G6, are shown in their relation with the differential gearset G7, with the jackshafts terminating in square ends, mounted on annular type ball bearings, ending in flanges F1 and F2 at the extremities where the dog drive engages the hubs of the wheels, thus delivering the power thereto under conditions of great flexibility. The live rear axle is of the Stearns type, with solid I-section forging, yoking around the differential at D1 and D2 in the customary way.



J—Working drawing of the crankshaft of the Stearns-Knight motor, giving all dimensions

K—Presenting details of design of the linkages and levers, indicating the means available for purposes of adjustment

L—Section through the brakedrums in the plane of the axle, showing the substantial bearings and other refinements

By referring to Fig. F it will be seen how the jackshaft J1 is flanged F1 at its extremity and engages the hub H1 of the rear wheel, and a further examination of this section will show the use of Timken roller bearings R1 and R2, held in place by locking washers L1 and L2, with a closure C1 at the back to keep foreign matter out. The flange F2 of the hub is extended to take the outer brakedrum B1 on one side and the inner brakedrum B2 on the other, they being clamped to the hub flange on finished faces by rivets R3.

To get an idea of the details of the two sets of expanding brakes in the double drums as they are bolted to the rear wheels it will be necessary to examine Fig. H, which is a partly sectional plan in the plane of the wheel and the section Fig. L in the plane of the axle. It will be seen in Fig. H how the adjustment mechanism M1 actuates a lever L1 with a cam C1 pressing against the jaws J1 and J2 forcing the shoes outward, and looking at the diametrical opposite side of the outer brake it will be seen how the lever L2 actuating the cam C2 engages the brakes. The inner brakes are adjusted in precisely the same way, the only difference being that the mechanisms are reversed. Grease cups are placed at points of vantage, the idea being to prevent wear and to save noise.

Fig. K shows some details of the linkages and the levers and the shape of one of the pedals with adjustable yokes Y1 for the rods R1, with locking nuts N1 at every point.

Referring to the front axle A1 in Fig. A, of the I-section, attention is called to the knuckle K1 with a pin P1 and a grease cup G1 placed at the upper end for purposes of lubrication, and to the knuckle spindle S1 with Timken roller bearings R1 and R2 in the hub with a safety washer S2 held in place by a locking nut N1 with a hub cap H1 over all, and a closure C1 at the back to exclude dirt. This axle is of the Elliott type, and the distance between the yoke supports is adequate for every end. The steering arm A2 is a taper fit in the knuckle lug L1, and it is prevented from turning by a key K2. The extremity of the steering arm terminates in a large diameter ball B1, which is of hardened

N—Torque characteristic of the Stearns poppet valve type of motor given for purposes of comparison with the torque characteristic of the Stearns-Knight type of motor

steel, with a press fit in the enlargement of the knuckle arm pulled to tightness by a locking nut N2.

The steering post is shown in section Fig. I, with a worm W1 engaging a wheel W2, with means for adjustment between cup and cone ball bearings B1 and B2. For purposes of adjustment the mechanism M1 with threaded portions is provided. The spark and throttle levers are in concentric relation within the tube, and the steering wheel is of large diameter with a fluted rim, securely fastened to a substantial dished spider.

Why the Stearns Design Had to Be Revamped to Accommodate the Stearns-Knight Motor

Despite the excellence of design and construction of the Stearns poppet valve type of motor as it was refined through several years of practice, it was found that the new Stearns-Knight motor delivers considerablely more power and performs with an entirely different characteristic in hill climbing and on long stretches of bad roads. As will be well appreciated by those who have given the matter thought, the crankshaft and other rotative members in the torquing system of an automobile, if they fail at all, will do so during the period of maximum power delivery at slow speed. It is in the ability of the Stearns-Knight motor over the Stearns poppet valve motor to deliver a larger measure of torque at the lower speed that required the reconsideration of the chassis designing problem, and the whole matter was finally disposed of by refining and strengthening the Stearns chassis to suit the new conditions, but for the purpose of clearness here it is considered desirable to give the results of tests of the Stearns poppet valve motor and of the Stearns-Knight motor.

The Stearns-Knight motor, which the author examined and photographed after taking it apart, has cylinders with a bore of 4¼ inches and a stroke of 5½ inches, making the cubical displacement 312.082 cubic inches, which would give an A. L. A. M. rating of 28.9 horsepower. The power of this motor as determined by test on February 3 and 4, 1911, was as follows:

The poppet valve motor has four cylinders with a bore of 4½ inches and a stroke of 4⅝ inches, with an A. L. A. M. rating of 32.4 horsepower. It will be seen that the poppet valve motor is of larger bore than the four-cylinder Stearns-Knight motor, and comparing the power of the two motors at one point only for the moment, the Stearns-Knight motor delivered 44.4 horsepower at 1200 revolutions per minute, whereas the Stearns poppet valve type of motor delivered 36 horsepower at the same speed, and the Stearns-Knight motor delivered a torque of 170 pounds, whereas the poppet valve type of motor delivered a torque of only 150 pounds at 1200 revolutions per minute. The maximum power of the Stearns-Knight motor was 64.1 horsepower at 2290 revolutions per minute, and the maximum power of the poppet valve type of motor was 51 horsepower at 2220 revolutions per minute. In a further comparison of the characteristics of the two motors reference may be had to the speed torque curves, as shown in Figs. M and N, which is the most fitting way of disposing of the matter.

Proper Form of Carbureter Cock

It is not uncommon, in connection with carbureters, to observe that the cocks are of the sort usually found on gas fixtures and other work in which the ills of vibrations are not figured upon. For carbureters it is scarcely to be expected that the ordinary form of cock will do the work without giving a certain amount of trouble, and the proper form of cock should be one provided with a spring-locking device, so contrived that the cock cannot jar loose. The lock consists of a pin in the stem of the valve which engages a nick in the housing. When the valve is turned the spring compresses enough to allow the pin to slide out of the notch in the housing without any trouble at all. The crank on the stem is also weighted, and the weight hangs downward when the cock is in the closed position. This is an additional safeguard that is of good value, and the cost is really nothing extra. If all cocks are so devised, it is then that the autoist can see, at a glance, if the cocks are opened or closed.

Columbia Out with Knight Motor

Holding Closely to the Latest English Version

Illustrating and describing the Knight motor used in the new high-powered Columbia car for 1912, showing close agreement between Columbia practice and the work that is being done in England under the direction of Charles Y. Knight, of Coventry, the modifications, such as there are, being in the chassis, for the purpose of bringing the same up to the new requirement in view of the characteristic of the sleeve type of motor and for the purpose of harmonizing the existing relations. The finished article is designed to conform to the demands of American road work, following along the lines that are characteristic of Columbia automobiles as they are known to the industry.

SIGNIFICANT of the trend in motor work, the new Columbia-Knight motor as made by the Columbia Motor Car Company, of Hartford, Conn., is here presented, the motor being of the four-cycle type with cylinders cast in pairs, with an A. L. A. M. rating of 38 horsepower, but the power delivery will be that due to a bore of a 4 7-8 inches and a stroke of 5 1-8 inches. The actual power, according to tests made, ranges between 70 and 85 horsepower. While the motor follows the general lines as practiced under the direction of Charles Y. Knight in his work abroad, an effort has been made to reduce this practice to conform to the requirement from the point of view of this company, and Charles E. Reddig, chief engineer of this company, went into the matter at some length with Inventor Knight, and agreement was reached between them to the furtherance of the plan. The experiences that were gained at Coventry in the working out of the Daimler-Knight motors were taken advantage of in the designing of the Columbia-Knight motor, and in the materials as they are used in the newer effort, there is close agreement with the plans that have served abroad.

The details of design and construction of the new motor may be clearly appreciated by an examination of Fig. O, showing a section through one of the cylinders at right angles to the plane of the crankshaft. The piston P1 is shown at the top of the stroke, and the connecting rod C1 of the I-section has a split enlargement, and clamping of the crankpin bearing C2 is accomplished by means of four through-bolts B1, etc., using plain bearings and white metal lining. A dipper D1 scoops oil out of the adjustable receptacle S1, and the excesses of lubricating oil fall down into the oil reservoir R1, and the quantity of oil present in this reservoir is indicated by the position of the tell-tale T1, which is actuated through the buoyancy of the float F1 in the manner as shown. Referring to the sleeves in their concentric relation to the piston in the cylinder, the long sleeve S2 on the inside is actuated by the connecting rod C3, and the short sleeve S3 between the long sleeve and the cylinder is actuated by the connecting rod C4, both connecting rods being given reciprocating motion by the eccentric shaft E1, and power is transmitted to this shaft from the crankshaft by means of a silent chain, engaging suitably contrived gears placed in an oil-tight housing at the front end of the motor. Recognizing the necessity of maintaining good conditions of lubrication of the sleeves, the chamber C5 is fashioned in the crankcase, and the oil that reaches this chamber is guided in its upward travel reaching the point O1 for the lubrication of the outer sleeve, and the point O2 for the lubrication of the inner sleeve, and the oil thus applied to these surfaces is drawn up between the sleeves and between the outer sleeve and the cylinder wall, maintaining an even coat of the lubricating oil over all of the surfaces, so regulated, however, that a smoking exhaust is avoided. Some of the lubricating oil reaches the surface S4, and experience shows that the junk ring J1 is maintained in a good state of lubrication at all times, but since all of the lubricating oil that reaches the junk ring surfaces must come into contact with the packing rings above the junk ring it goes without saying that these packing rings are properly lubricated also.

It will be seen how the spark plugs P2 and P3 are screwed into the detachable cylinder head, and attention is called to the water jacket W1 of the head, circulating water all around the spark plugs, thus overcoming one of the little difficulties that was

Fig. V—Front end of the Columbia-Knight automobile, depicting the general appearance of the car formerly experienced in the Knight type of motor, resulting in the melting out of the spark plugs after a certain time in service. A further examination of the water jacketing shows that the lips L1 and L2 of the inlet and exhaust ports have been carefully looked after with a view to maintaining proper conditions of cooling, and the passageways for the incoming mixture and the exhaust products are of smooth and symmetrical shape. In this design of Knight motor the water connections W2 and W3 are flanged to finished faces on the sides of the cylinder heads, rather than taking a position on the top of these heads. In the designing of the cylinders, some of the early difficulties in the foundry have been overcome by a closer attention to detail in the matter of coring, and it will be seen how the cylinder heads are bolted to finished faces F2, making a "ground" joint, to the elimination of packing, and the difficulties that are suggested by its use. The motor arms A1 and A2 are cored and the breather R2 is shown screwed into a boss on the top side of the arm A1. Access is had to the crank chamber through handholes H1, for which covers are provided.

Referring to Fig. R of the motor in perspective with a part of the crankcase cut away and three of the cylinders shown in section, it will be seen how the eccentric shaft E1 takes its power from the crankshaft C1 through the silent chain S1. The crankshaft is provided with main bearings M1, M2, M3, M4, M5 and M6, the latter two of which do not show in this illustration, being covered up by the shell, and the eccentric shaft is also provided with bearings B1, B2, B3, B4 and B5, the latter two being also hidden by the shell. The crankshaft is of unusually large diameter, bored hollow, and considering the use of a bearing on each side of each throw, and the rigidity of the bearing supports, it will be seen that the designer has filed his brief for rigidity in a manner consistent with the power characteristic of this type of motor. This view shows the commodious oil reservoir R1, and the positions of the tilting oil troughs O1, O2, O3, there being four, also a screen S1 between the oil troughs and the body of oil below, it being the idea not only to carefully regulate the supply of oil to the several bearings, but to filter and clean the same as it is directed back into the reservoir. This illustration affords an excellent idea of the general appearance of the motor, there being a certain symmetry of the exterior of the cylinders, and the crankcase is extended up to meet the somewhat shortened cylinders, thus giving an appearance that is at variance with common practice in motors in general. In this view it will be seen how the water jacket separates the walls W1 between the pairs of cylinders, this being a bid for uniformity of cooling of the cylinder walls at every point, and in this connection attention is called to the small amount of clearance that has been found practicable, notwithstanding the fact that in the earlier practice of the British Daimler Company the piston was given a clearance of as much as .012 of an inch, which considerable amount of clearance was reduced from time to time, until to-day it is not uncommon to see these motors operating with the piston clearance reduced to .004 of an inch. This phase of the designing problem led to another practice that has proved to be efficacious, in which the pistons are backed off, excepting on the pressure zones, and in view of a desire to limit the reciprocating weight to the greatest possible extent, this backing off idea lent facility to the plan, since it permitted of making the pistons so thin of wall that they might deflect a little at the instant of maximum pressure; but this makes no difference at all in the operation of the motor, since the taking on of a slightly elliptical shape is compensated for by the amount of the backing off, which permits of holding to a sufficient clearance for all working purposes, and the gain is marked in the direction of reducing the secondary moments, thus making the running balance all that it should be. In this motor, as the illustration shows, the driving of the rotative members is by a silent chain for the eccentric shaft, including the magneto and the water pump. The only drive that is not by the silent chain is that of a fan which is by a belt from the pulley P1.

In the sectional drawing U, the magneto M1 is shown resting upon a finished face on the arm of the motor at the right side, and it will be seen how the magneto comes in the vertical plane above the top flange of the sidebar. This is a direct bid for accessibility of the magneto, and a further examination of this reproduction of a working drawing adds to the conclusion that the designer had in mind the desirability of affording access to every vital part, rather with the expectation that much unnecessary tinkering may be avoided if the operator can see the parts and observe of their condition. In other respects this reproduction of the working drawing shows nothing beyond that which can be seen in the section O, excepting that it does bring out very clearly the perfect uniformity of the walls at every point and the freedom from the bunching of the metal. This method of designing produces better castings with greater ease of making them, and the number of "wasters" that will abound under foundry conditions are reduced to such a low level that the difficulty involved and cost of production of the castings are on a favorable basis. Before departing from this illustration, attention is called to the hanger, or bracket, H1, attached to the arm A1 by means of a holding bolt B1 for the suspension of the motor at the left side, and to the somewhat different shaping of the hanger H2 attached to the arm A2 by means of a holding bolt B2, and to the reinforcement R1 of the chassis frame at this point.

One of the pairs of cylinders separated from the motor is shown in Fig. T with one of the pistons setting in front of it, and a pair of the sleeves as they came out of one of these cylinders is presented in Fig. Q. It will be seen how the pistons are depressed in the heads, and attention is called to the grooving of the sleeves and to a series of small holes drilled through their sections, it having been found in practice that it is better to relieve the lubricating oil at certain points and to afford storage pockets for the excesses thereof rather than to attempt to maintain an unbroken film for the whole pressure area of each sleeve. It is more than likely that this series of grooves as they obtain in the sleeves retard the upward migration of the slowly-moving body of oil and in this way lubrication is rendered stable, and the probability of an excess of lubricating oil getting into the chamber, fouling the mixture and causing a smoking exhaust, is done away with.

One of the cylinder heads is shown in Fig. W tilted to bring into view the cavity C1 within, and to show the joint J1 of the junk ring. Fig. Z gives another view of one of the cylinder heads, bringing into view the pair of packing rings above the junk rings, also the holes for the holding bolts, the latter being clearly shown in the cylinder heads in Fig. T. One of the connecting rods that impart motion to the sleeves from the eccentrics are shown in Fig. X, and one of the connecting rods which are used to impart reciprocating motion to the pistons is offered in AA. The crankshafts, together with the eccentric shaft, are shown in Fig. Y.

Other Important Matters in Relation to the Columbia-Knight Motor

Among the details of design and construction of the motor, there is perhaps no point of greater importance than that as represented in the fact that the cylinder castings and the castings of which the sleeves are made are produced from Swedish iron. The timing of the motor may be varied over a broad range at the will of the operator, so that in this respect this type of motor is without limit, and in the matter of compression, while the motor is "soft" to crank, the torque characteristic indicates that it is on an increasing basis as the speed increases, receding only after the speed reaches practically the working maximum, as this point in the performance is dictated from considerations of lubrication involving the piston travel as it is measured in feet per minute. With every advantage in the direction of favorable timing, including the use of large ports and water-jacketing around the ports, it is found that the motor scavenges advantageously and that the effort required in cooling recedes to a low level, and it is in these directions that evidence comes of the fact that the motor should deliver a large measure of power per unit of displacement, performing under wide conditions of flexibility, but the point that seems to be of the greatest moment lies in the fact that service does not seem to induce a condition of leakage with its attending loss of power. The accumulation of carbon in the combustion chamber is at a very low rate, and the carbon that gets between the faces of the sleeves is mixed with lubricating oil, and all of it that remains on the surfaces fills in the interstices of the metal, serving as a lubricant on the same principle that graphite is employed in cylinders for lubricating purposes.

The ignition system is the Bosch double outfit with two sets of spark plugs.

From the motor through the clutch to the four-speed selective type (including reverse) transmission gear, as shown in Fig. S, is through rugged mechanism characteristic of last year's Columbia practice, and the nesting of the gears is shown in Fig. P, in which it will be observed that the prime and lay shafts float on annular type ball bearings, the latter being nested in protective housings with closures to retain the grease used in the lubrication of the ball bearings, keeping out foreign matter, and in the shaping of these housings they are so flanged and otherwise provided that the projected area of the pressure surface against the aluminum of the case is maximum and a liberal surface is provided in the planes of thrust. The arrangement of the transmission gear amidship and the placing of the control lever with the emergency brake lever in the center of the body, to be operated with the left hand, leaves a free entrance into the front seats of the car from either side, but it is optional with the purchaser to have the levers placed at the right side in the conventional way. From the transmission gear through the propeller shaft to the live rear axle is the normal course of the torque of the motor, and the axle, being of the full-floating type in a malleable iron housing, shaped for strength, built up in conjunction with tubes under conditions of hot riveting, promises to sustain under the load and road conditions adequately for the end. Access may be had to the bevel drive of the differential housing through commodious bolted-on covers. The differential housing is drop-forged. The pinion and pinion shaft are forged integral, mounted within a cage upon Timken short-series bearings, and may be removed bodily. The bevel drive and differential gear also float on Timken conical roller bearings. The plan of resisting torsion involves the use of a triangular "U"-section pressed steel member tied to top and bottom of axle housing, and leading forward to a flexible connection at a suitably contrived cross bar. The brakes are of large diameter on the rear wheels, and compensation is through a whiffletree transmitting the effort by rods to pedal and lever. The wheels are 36 inches in diameter, and the wheelbase of this model is 129 inches.

The general appearance of this car, looking at the front, is shown in Fig. V, and the I-section front axle of the Elliott knuckle type is in plain view with substantial drop-forged knuckles and stout knuckle arms with a cross rod in the protected position back of the axle, and a straight drag rod leading to the steering arm interpreting the effort of the driver exerted on the steering wheel in the maneuvering of the car. The axle is of the drop type forged in one piece with integral perches for the springs, and the half-elliptic springs in front are designed in view of the condition of constant loading as represented by the motor for the most part, care having been taken to fix the load per inch of deflection of the front springs within the zone of stability, remembering that any pitching that is induced at the front end of the car complicates the body movement at the back, making it extremely difficult for the designer to promise easy riding qualities. Having fixed the spring condition at the front on the basis of an even platform, it remained for the designer to so fashion the back springs that the vertical oscillations would be on an agreeable basis, perhaps in the neighborhood of one and a fraction per second. The importance of utilizing the large amount of power that is promised by the use of the Knight sleeve type of motor has made it necessary to study the distribution of weight in the chassis, and account has been taken of the fact that a mere low center of gravity has little to do with the truly good performance that practice supports. Having extended a due measure of attention to questions of clearance, it remained to distribute the mass as it is represented by the power plant, so compacting it as to avoid top-heaviness; in other words, the machinery equipment, as nearly as possible, forms a sheet in close proximity to the center of gravity, resolving the latter from the increments of a closely related mass rather than otherwise. It would be too much to expect that a motor with a high torque characteristic could be used in a chassis and have it perform with entire satisfaction without taking due account of the relating situations, and it has been the purpose of the designer in this case to harmonize these relations and obtain the best result.

From the Point of View of the General Appearance of the Car

An examination of the title illustration will suffice to show a flush side type of body of the vestibule design with fore doors, and as a conspicuous incident of this design the great width of the doors may be looked upon as a factor. The space within the vestibule is considerably more than that of last year in this make of car, and comfort from the point of view of the occupants of the automobile has had a wide influence upon the activities of the designer. The cushions of the seats are 10 inches high, with a smart pitch to the rear and the use of long coil springs in conjunction with the best grade of curled hair has fortified the undertaking. The seven-passenger body as shown is almost severe in its straight-line effect, and a part of the satisfaction that has been obtained is due to the continuation of the line of the bonnet in the plane of the flush side paneling of the body. Having designed the front seats with a view to comfort in driving, which is apart from the consideration that influences activity in the rear seat work, it remains to state that the rear seats span 53 inches, are proportional in depth, and comfort is further assured by plenty of knee and leg room in the free space in front of the seats.

Among the body options, the six-passenger type is worthy of particular mention, this body being with straight sides without molding or decoration, and the rear seat is 44 inches wide. The extra seats in the tonneau are of the collapsible and folding type, dropping into the floor so that they are out of sight as well as out of the way when their use is not called for.

The close-coupled roadster represents a particularly smart undertaking with room for an extra "case" upon the rear end, with a back and trap-door entrance to the auxiliary storage space which is afforded by the design.

The two-passenger roadster is a strictly gunboat type of car with a large capacity gasoline tank, and a tourist's trunk so placed as to be out of the path of dust and dirt.

In fitting out these automobiles, while it has been the aim to afford to the company's clientele as much of auxiliary equipment as could be foreseen on a conservative basis, the fact remains that there has been a fair attempt to avoid the "undue" loading of the car, and the equipment decided upon in view of this consideration includes a cape top with top boots for all models, demountable quick detachable rims with extra spare carried rim, power tire inflation pump, complete electric lighting equipment, a well-contrived horn, ignition and lighting battery, supplemental to the Bosch high-tension magneto, shock absorbers, robe rails, foot rests, rear hamper for storage, trunk rack, locker for goggles and gloves, a full regular set of tools with proper means for holding them, and among other incidentals a registration plate holder.

In the schedule of the automobiles that will be turned out this year a certain amount of attention is to be given to coach bodies, and of these types of cars as listed in the preliminary announcement mention is made of a seven-passenger limousine vestibule with fore doors, fitted with glass enclosing side storm panels for the driver's seat, and Berline type double enclosed limousine, straight front and hooded landaulet, not to mention the types of body work that will be entertained in the event of demand.

The Columbia Line Will Include a Poppet-Valve Type of Power Plant

In addition to the new Columbia-Knight type of power plant it remains to state that the company is building a 38-horsepower poppet-valve type of motor with T-head cylinders in which the approved mechanical features of the 1911 Columbia motors have been retained, and the design has been brought up to date in all minor respects. In this motor the cylinders are cast in pairs with a bore of 4 7-8 inches and a stroke of 5 1-2 inches, thus making the A. L. A. M. rating 38 horsepower. The new features of this motor include a pure-air pressure system for the gasoline supply, and a motor-driven tire inflation pump. The carbureter is raised, thus permitting the manifold to be so shaped that "loading" is avoided, and it might be well to say that the pure-air device which furnishes pressure to the gasoline tank is a separate equipment from the power air pump. The carbureter is located on the left side of the motor in the mid position, and the Bosch magneto rests upon a shelf just back of the front arm on the same side of the motor, and by way of an innovation the magneto is provided with a brake to be used in locking the driving shaft in a definite position during the time that the magneto is disassembled from the motor for purposes of inspection and repair, thus assuring the repairman that the timing will be undisturbed, since the magneto may be put back into precisely the same position that it previously occupied, and to release the brake is then the only remaining consideration. The oil pump is driven by a vertical shaft extending down from the camshaft and the pump is located horizontally in clear space between the oil sump and the flywheel. The timer is driven by an extension of the same vertical shaft and it is placed on the top of the crankcase well clear of the flywheel. Looking at the right-hand side of the motor shows the centrifugal water pump in the mid position driven by a shaft with a gear in the halftime train, and the power air pump is placed between the water pump and the rear arm of the motor, taking its drive by means of a gearset with one member on the pump shaft, and by means of a lever that is conveniently placed the gears are meshed when it is desired to operate the power pump. The oiling system in this motor includes a commodious sump in the lower half of the crankcase for the supply of oil, a means for determining the oil level, and facilities for draining out the oil when it is desired to clean the system. The details of the motor are in excellent keeping with the main idea, taking into account the fact that users of automobiles will be safe in choosing a sleeve type of motor on the one hand or a poppet-valve type of motor as a substitute, either of which will fit harmoniously into the chassis and do the bidding of the owner.

Steam vs. Gasoline

There seems to be an idea among the heads of some municipal fire departments that pumps driven by gasoline motors are less effective than those driven by steam. In the adoption of a gasoline automobile fire-fighting system the advantage of having the same power propel the vehicle and pump the water is obvious, and there are many examples of the successful operation of this combination.

INTEREST is being centered in the problems that confront the fire departments of municipalities from the point of view of the substitution of automobile fire equipment for the old kind. Every progressive community fully understands that the automobile fire equipment is better in every way, but among the men who are charged with the various duties involved in the changing over there is an air of uncertainty, due to the fact that they fail to appreciate the significance of certain of the problems, and they are too prone to believe that there is some peculiar merit attached to a steam pump, for illustration, that is found wanting when a pump is driven by a gasoline motor. The probabilities are that quite a number of the activities of these men are based upon mere superstition. The delivery of water from one point to another requires power on the same basis as the delivery of coal, or, for that matter, gold from a mint. The delivery of water or other compounds is at the expense of power, but it is too much to expect that the water delivered will express a preference for a horsepower from a steam engine rather than a horsepower from a gasoline motor. It would be foolish to discuss this matter were it not for the fact that the engineers in the various fire departments are talking among themselves on this basis, and it is a little alarming that some of them labor under the impression that a gasoline motor of a given power is at a disadvantage when it is driving a water pump as compared with a steam engine of the same power when it is used to drive the same pump.

Adulteration Bane of Good Varnish

Thinning and Binding Materials Play an Important Part

M. C. Hillick discusses the problem of painting and varnishing of automobiles and entertains the reader in a discussion bearing upon the subject of adulteration as it is practiced in paints and varnishes, ending up by stating the relation of the thinning and binding mediums that find a place in this class of work.

TO the automobile owner and the automobile painter the question of purity of paint, color and varnish thinning and binding mediums, consisting principally of turpentine and raw linseed oil, is of the utmost importance. Within the past two years there has developed an increasing complaint concerning the failure of the paint and varnish structure—that is to say, the finish—to wear as all those interested have a right to expect it to wear, and within the past few months there has come an urgent demand for an explanation of the lack of durability of the automobile paint and finish.

There are, of course, many reasons, both logical and, it would seem, convincing, to be offered in justification of the lack of durability of the automobile finish, but probably the foremost reason to-day is that of sophisticated or substitute thinning and binding mediums, confined chiefly, we believe, to turpentine and raw linseed oil. At this writing raw linseed oil in barrel lots is quoted at 90 cents a gallon, and turpentine in five-barrel lots is on the market at 60 cents a gallon. These quotations are considerably lower than those prevailing a few weeks earlier in the season, but they are still sufficiently high to move the unscrupulous manufacture or jobber to resort to adulteration as a means of easing up the market and increasing his profits.

The adulterated raw linseed oil may and often does contain anywhere from 20 to 30 per cent. petroleum in its various forms, and the substitute oils, of which we are just now hearing news in plenty, are often found to contain as high as 50 per cent. of rosin oil or petroleum. The average paint-shop proprietor, or his foreman painter, lacking a definite knowledge of chemistry, is at a disadvantage, acting alone in the matter, in any effort he may make to determine the character of the oil supply. The best he can hope to do, and the very best he can do, in fact, is to deal direct with some strictly reliable jobber, or, better still, with a crusher of established trade reputation. A sophisticated oil, or an oil substitute, containing, say, 25 per cent. petroleum, rosin oil or some other equally undesirable medium, puts the buyer in a position of paying at the rate of 90 cents a gallon for petroleum or rosin oil; and in the event of the adulteration or substitution reaching a 50 per cent. basis it is easy to understand the element of chance introduced. For determining the purity of raw linseed oil a hydrometer, an inexpensive little instrument, may be used with good results. A pure linseed oil, by the hydrometer test, should not vary 1-2 degree from 20° to 60° Fahr. Simple tests for the purity of the oil may be carried out as follows:

Mix equal parts of the oil and ammonia together. When cottonseed oil is present the ammonia drives the liquid to an opaque yellow. Fish oil under the effect of the ammonia grows white. A simple and effective test consists in taking a couple of test tubes and putting a quantity of linseed oil of known purity in one tube and a quantity of suspected oil in the other, then immersing the tubes in warm water for one-quarter of an hour, and immediately upon removal from the water pouring the pure oil into the tube of suspected oil. Should there be existing impurities different colors will form in layers.

Turpentine, the universal and indispensable color and varnish-thinning medium, is at the mercy, apparently, of the adulterators and substitute orators. Sophisticated turpentine, or turpentine substitute is causing more trouble among a very large class of automobile users and painters than almost any other one thing.

Speaking from a practical point of view pure turpentine may be said to be indispensable. It is the paint, color and varnish-thinning medium *par excellence.* To get at the purity and, therefore, the real value of turpentine the hydrometer may very well be impressed into service. Strictly speaking, a turpentine of the greatest use in the finish of the automobile should not register above 31 1-2°, or below 30 1-2°. As a matter of fact, —or, perhaps, we should say, as a matter of business—the automobile painter, and, back of him, the automobile owner, should insist upon 31° turpentine. Sophistication of the turpentine is widespread—countrywide, we should say—and it consists chiefly of mineral oil, which medium, at its best, retards the drying of the pigment and renders its action more or less uncertain.

In turpentine substitutes there are many which contain only perhaps a small percentage of non-volatile lubricating oil which is said to come over in the fractional distillation process used in the manufacture of this material from the crude petroleum. But this minute quantity of lubricating oil is in itself sufficient to render any paint or varnish containing it uncertain in its action and devoid of its maximum durability.

A turpentine substitute composed mainly of a product obtained from the steam distillation of pine strips and logs, commonly known as "wood spirits," and, if pure, will yield very good results, as a rule. Chemists, we believe, claim that wood spirits has greater solvent power than pure turpentine, but it is deficient in those properties which have made turpentine famous the world over.

There is another class of turpentine substitutes, or materials with which pure turpentine is sophisticated, that it is worth while to here briefly consider. These solvents are obtained from coal tar and include xylol, naphtha, tolnol, benzol, and thinners of a similar nature. Practically all of these mediums possess unusually active solvent properties, and while the much lower price at which they are sold is an inducement to certain branches of the trade the inferiority of the mediums for use in the automobile finish is so pronounced that their chief use is confined to the manufacture of varnish removers and for other purposes wherein the durability and working properties and appearance of pigments is not a matter at issue.

A class of turpentine substitutes, or a class of turpentine adulterating mediums, which have attracted large attention, and which are likewise considerably used both as turpentine substitutes and turpentine extenders, to speak in charitable phrase, are derived from crude petroleum by the process of fractional distillation.

In the matter of flash point and solvent properties crude petroleum derivatives approximate very closely—almost precisely, we might say—to the pure turpentine. To subdue the flash point and hold it down the manufacturers arrange to have a certain quantity of heavier oils distilled over, which latter mediums bring the marketable product into close relationship to the naphtha and ordinary kerosene group of oils, and render them unfit, even when employed in comparatively minute quantities, for use in fine automobile paints, colors or varnishes.

Ontario, Model of Road Building

Province Has Solved Problem of Highways

Most populous of the Canadian states has 50,000 miles of maintained roads outside the incorporated cities and has spent upward of $40,000,000 to make and keep them. The Provincial Government has contributed over half of the sum mentioned. In parts of the section the clumsy system of working out road rates is in vogue, but the majority of the counties have adopted the most modern system of road building and maintenance. Toronto, magnificently paved itself, is one of the few large cities on this side of the Atlantic that has ever contributed a penny to road work outside its own limits.

TORONTO, July 3.—There are approximately 9000 automobiles in active service within the Old and the New Provinces of Ontario, Canada. For the accommodation of these motor-cars, 50,000 miles of public country highways —exclusive of all city roads—are maintained, of which 40,000 miles gridiron the Old Province and 10,000 miles thread the New Province. All of the work of repairing and maintaining the established thoroughfares and building new ones, is carried on under the direct supervision of Mr. W. A. McLean, C. E., Provincial Engineer of Highways to the Ontario Highway Improvement Bureau. These country roads penetrate through 500 Townships and 37 Counties in Old Ontario; and 8 Counties in New Ontario.

There are portions of the Townships in Old Ontario which still adhere to the feudal basic principle of keeping up the rural roads, the system literally corresponding with that in vogue in certain sections of the States, whereby the farmers "work out their poll-tax," by contributing each their respective share of manual labor. Nineteen Counties out of the 37 have adopted the new County system of road-building. This means that the highways of the nineteen Counties are improved and maintained under the regulation Provincial method. This system embraces three provisions which the road-builders in Counties are compelled to abide by. Each highway must be built either of gravel or macadam; steam-rollers must be used in the process of construction; and the highways must be thoroughly and symmetrically graded. The system in its entirety, as it is found to-day, was adopted in 1901. A summary of expenditures in the Townships of the 45 Counties in the two Provinces shows that cash to the amount of $19,015,343 was paid by the Government for the up-build and maintenance of roads from 1889 to 1908; to which must be added about $750,000 per year during 1909 and 1910. There is now being built an automobile trunk-line road 300 miles long, from Sudbury to Sault St. Marie, and skirting the north shore of Lake Huron, the expense of which falls upon the shoulders of the Provinces of Ontario, the Counties contributing absolutely nothing.

This highway will constitute the finest automobile route in the Dominion of Canada. Independent of this highway, sixteen Counties have put up one-third to the Provincial Government's two-thirds, in an outlay of nearly $4,000,000 for the purpose of building roads. The result is that the highways of these Counties are the best in the Western portion of the Old Province of Ontario. One essential feature of the system of road-building in question is that the Provincial Government will not extend aid to individual Townships. Co-operation must be complete. Every Township in a County must come in as an integral part, or the whole County must stay out.

A single exception to this rule is found in the instance of York County, of which Toronto, with its sublimely paved streets, is the metropolis. Toronto took a hand in building outside of its own municipal limits. This is the only city in the Dominion of Canada that has ever extended financial aid for the purpose of constructing automobile roads not within its own confines. But in this case the city contributed $100,000; the Provincial Government gave $100,000; and the Southern, or lower, half of York County put in $100,000, making a total of $300,000. The Northern, or upper half of the County declined to affiliate, on the ground that its own roads—built out of gravel, and some of which are worse than others—were quite good enough for automobiles to travel over, without plunging into the Treasury.

The $100,000 given by Toronto is absolutely independent of the appropriations made for augmenting and maintaining her own city roads. These comprise within the mnnicipal limits 407.57 miles of streets and 115 miles of lanes. There are 262.13 miles of

D—A fine stretch of road in Oxford County E—Chestnut Park Road, Ontario—A stunning driveway
F—A normal road in old Ontario Province—good automobiling is promised

the streets which are paved and 145.44 miles are unpaved. The kinds and miles of pavements and roadways follow:

Asphalt	118.44	miles
Cedar blocks	17.71	"
Brick	25.41	"
Macadam	45.91	"
Wood and concrete	0.49	"
Stone and scoria block	2.34	"
Gravel	21.35	"
Bitulithic	20.68	"
Tar macadam	3.88	"
Concrete	1.98	"
Asphalt block	4.14	"
Unpaved	145.44	"

The streets designated as being unpaved include quite a number which have been improved by macadam pavement.

The system of paving with asphalt was introduced in Toronto twenty years ago, and every yard of this pavement is laid on a concrete foundation of from four to six inches with a one-inch binder course. The specifications demand a two-inch surface of asphalt.

Such a thing as a paving company securing a contract through political intrigue or graft in the Dominion of Canada is absolutely impossible. Not only have Toronto, Ottawa, Hamilton and Winnipeg asphalt paving and repair-plants of their own, but in the event of a new street being paved, or an old one repaired, the respective municipalities advertise for tenders and the contract goes to the lowest bidder, independent of the city's plant, in case the outside bidder's figures are below those proposed by the city's own engineers.

Ottawa, Hamilton, Kingston, London, St. Thomas and St. Catherine all make use of asphalt for the paving of streets; but the smaller the town, the less asphalt is used, to the advantage of brick and macadam.

The comparison between the maximum, minimum and average prices for paving with asphalt, as shown in a table from 1901 to 1909, follows:

	Maximum.	Minimum.	Average.
1901—Heavy	$2.70	$2.30	$2.54 6/10
" —Light	2.23	1.88	2.04 1/2
1909—Heavy	1.95	1.59	1.72 2/3
" —Medium	1.80	1.40	1.60
" —Light	1.44	1.12	1.28

The extremely low prices shown during the year of 1909 were brought about rather by the keen competition existing among the contractors than by a reduction in the actual cost of pavement. However, the prices for 1910 do not vary materially from those of 1909; while the city officials anticipate about the same prices for 1911 as those which have prevailed during the last two years.

Automobiles within the Old and the New Provinces of Ontario regard the conditions as they relate to country and city in general, as being satisfactory, so far as the laws are concerned. Proprietors of automobiles pay a registration fee of $4 yearly. Chauffeurs pay a fee of $1 each. They are not required to undergo a technical examination. But the majority of those who drive for owners of private motor-cars have visited the States extensively and are up-to-date. They have neither union nor club. Their wage is about $60 per month.

The Ontario speed-limit in rural districts is 15 miles; while 10 miles obtains within the confines of cities. Search-lights are prohibited. Gasoline sells for 20 to 25 cents per gallon in small quantities and about 15 cents in bulk.

The customs duty on assembled automobiles brought into the Province is 35 per cent. When parts are imported into the Province, or the machine comes in disassembled, the duty is 15 per cent. The duty on rubber tires is 35 per cent.

The great majority of the motor-cars now in use in Ontario are American-made. Great Britain comes second; with a scattering of machines of Continental European make, and a very small percentage of cars built in Canada. In fact, there are but three of the latter—all of which contain American or European-made engines. The Canadian-built cars sell for $2,600 to $5,500 Motor-cars of other makes are sold at the standard prices—exclusive of duty—which obtain in the States and Continental Europe.

The Toronto city officials have adopted motor-cars for official use, generally speaking. The Municipal Government appropriated $7,800 for the purchase of a combination hose-wagon and chemical engine for use in the Fire Department and tenders have been advertised for.

The Street-Cleaning Department has two automobile flushers and two trolley-car flushers in commission, all of which have proven to be a great success after two years of tests. They were made in England. The two automobile flushers do the work of 16 horses. They cover about 21 miles of streets in a nine-hour day, which represents the work of four watering-carts. It costs approximately 78 1-2 cents per mile with the automobile flushers, as compared with $2 with the horse-drawn carts. Each motor-truck costs the city $5,200, delivered.

The interests of automobilists are looked after by the Ontario Motor League, whose headquarters is in Toronto. It has a membership of 2,600, and it is affiliated with the Royal Automobile Club of Great Britain, thus affording its members touring in Europe the privileges of that Club. The Ontario Motor League grew out of the Toronto Automobile Club, which was established about ten years ago. The League stands for the protection of its members against adverse legislation; the general betterment of their interests; and the encouragement of careful driving on the part of chauffeurs.

Of taxicabs there are less than fifty in Toronto. The tariff per passenger amounts to 28 cents per mile. The vehicles were made in England.

How the S. A. E. Worked at Dayton

Discussion of Papers and Committee Reports

In the issues of THE AUTOMOBILE *of June 15 and 22 there were published the papers and committee reports submitted for consideration at the Summer Meeting of the Society of Automobile Engineers at Dayton, June 15-17. All the papers and reports were discussed at length by the members assembled, and many additional points of interest were brought out. A portion of this discussion was printed in a previous issue; the remainder, slightly abridged, is given herewith.*

WHEN the issue of June 22 went to press the stenographer who recorded the proceedings of the Summer Meeting of the Society of Automobile Engineers, at Dayton, had not transcribed all his notes. As much thereof as was finished, however, was hurried East, and appeared in connection with the story of the meeting. The remainder, with the irrelevancies eliminated, follows, beginning with the discussion on the report of the Broaches Division:

PRESIDENT: The next matter before us is the question of broaches.

MR. DAVIS: The canvass was made primarily to reduce the number of broaches used and to bring before the society, as you all know, the question of what really was the desirable standard to adopt, and to consider the whole matter from the manufacturing as well as from the engineering standpoint.

In our recommendations, first, we come to the spline shaft, and in that form the committee considered the matter from two standpoints. When I was here the other day in the preliminary meeting they asked me to have sketched out something that would give a little idea. (Puts sketch on blackboard.) This shows the two methods of fitting: One here—the hole ground to fit the mill portion of the shaft. This one here with the shaft ground to fit the broach portion. That is a matter that is not new in discussion, and I think the consensus of opinion of the committee was to recommend this form (pointing to same) as lending itself readily to manufacturing conditions. Our position in the matter being this that if, in machining, care is taken in regard to the broaches produced, if they are ground accurately and the sides ground, and that a hole can be broached sufficiently accurate to use it as a working point from which all finished portions on the gear shall be taken, and that the clearance can very readily be controlled because of this grinding upon the side. On the other hand, with the mill portion here it brings in the question of grinding the hole practically to the pitch line. There is quite a variety of opinion among manufacturers in regard to the loss in manufacture due to distortion from hardening or other causes, and due to imperfections in grinding to the pitch line.

As far as I have been able to discover in talking to engineers, the percentage lies in favor of using the finished broach hole as a working point, with necessary hardening to maintain size and then grinding the outer diameter of the shaft for proper clearance. That takes care of the question of the broached shaft.

Following that we come to the question of sizes, and to bring this matter before the society we sketched up this form. (Puts the form, with pins, on the blackboard.) In talking with a number of manufacturers—those who were not only using square shafts on gears for all purposes—the committee recommend, as a general standard, using the ratio between the short diameter, which is the distance across the flat and the long diameter or the diameter of the stock from which the square is made. Took that ratio as .8, and the full lines here will show you just about the proportions. This is drawn ten to one, and it shows you the relative portion of the form that is left. These sizes, in running from sizes up to inch and half, by quarter inch; and to three inch; and by half-inch sizes above that. And there it is, a sliding fit under extremely heavy duty; then carry out to dotted line, making the ratio .73. These are shown in the dotted lines, which brings it to quite a sharp point.

The committee felt that for the average practice that the .8 ratio will give good results both for sliding fits and for force fits, whatever difference there is between sliding fit and the other being made on shape. This narrows it down to one set of broaches for both purposes. It also narrows down the sizes taken within this ratio. We found by a canvas which Mr. Clarkson made that there were in use to-day something like 75 to 100 different sizes, varying by 1/64 or 1/32, and this narrows the number down to fourteen, and gives us a range which we think will give us practical results. Of course, it doesn't shut any one out from using special broaches if they see fit. But in general practice, for future designs, we believe that the range can be covered, and covered effectively, both from a manufacturing and a theoretical engineering standpoint by the adoption of these standards. There are a few errors in the table shown on page 5, and I am submitting a typewritten list here, showing those corrections which were made in the report as it comes before you later.

There is one other point that comes in the spline shaft, and that is the question of using even or odd numbers. From the manufacturing standpoint we feel that the best results were obtained, due to calibration and other purposes, by the use of even numbers. The odd number of splines is a difficult proposition to adjust and to measure accurately. As far as I know, in discussing the proposition the main argument in favor of the odd number is that it goes in the direction of the three-point suspension, possibly giving a little more accuracy. But in proper methods of manufacture it would seem to us that there would be no difficulty in using the even number, and that the advantages in favor of the even number would offset any advantage that there might be in connection with the adoption of an odd number.

There is another question in regard to the relative value of the square as against the spline shaft. The tendency at the present time is, we believe, toward the spline shaft. Of course, there is, as we all know, a combination of forces tending to open up the square that there is not with the properly made spline shaft, and there are conditions of manufacture in regard to the stock to be used where different sizes of square are to be used, which render themselves more readily to the use of splines. Personally, my preference would be in favor of the spline shaft.

MR. VON ROTTWEILER: When we talked about the subject yesterday, in standardizing these broaches, it should be found out how many splines we really want. One man wants an even number; the next man wants an odd number, and there we run in so many different sizes of broaches again. I think we should come to a decision as to how many splines we should use. Mr. Davis has had quite an experience in that line.

MR. DAVIS: I think the feeling of the committee was that on light cars four splines would be ample, and that we would hold to even numbers; but that on heavy powers, up to say over 40 horsepower and above that, that the six would be preferable as giving a little more satisfactory result. That is, it would give a greater factor of safety. But, as Mr. Souther has said, that is a matter of engineering judgment and in design in the various cars, our idea being that if the broach manufacturer is prepared to furnish either the four or six to standard size, then the matter of exact determination of that for any one designer would hardly be up to the committee, but that the society would adopt either the even or odd number as standard and the gradation of sizes as recommended by the committee, and then it would be up to the engineer of the various cars to determine whether he would use the four or six or the different size squares.

The idea was that it would be an advantage both to the broach manufacturer and to the manufacturer of parts to know that he could go and secure from stock, and the broach manufacturer also that he could manufacture in larger quantities, that in tallying up on various jobs to reduce the number to the smallest possible list, and at the same time have it effective, so that each one would be in a position to carry the work forward at practically the same cost in manufacture.

MR. SWEET: I would like to offer a thought in connection with locating on the outside of the driving lever. If we should adopt that, that makes it unsafe from the result that comes from a fire. It is practically impossible to fire that portion in solid. Whereas, if we locate on the hole, it will make it possible to grind the holes. In other words, they will be able to grind on both essential surfaces—the holes and the shaft portion. It would seem to me that that would be the better way because it would not make it objectionable to the manufacturer. We practice that in locating the bottom of the space. It would seem to me that there is advantage in not locating on the end of the dividing lever, but on the shaft on the hole.

MR. DAVIS: In covering that point it is true that there are manufacturers at present time that bring both the shaft and the bottom of the gears and the gear from the pitch line. Our main point in connection with that is in the one case, locating by the outside shaft, while it is true that we cannot grind at that point, if you choose that as a working point for all operations, it does seem to us that the percentage of loss or percentage of variation would be as small as you would get from working from any other point. Looking at it from a nicety of manufacture, it is undoubtedly true that you cannot grind both points, and possibly in some instances get a little closer result. On the other hand—I think we all have the same experience, that in gears particularly they get out of shape; they look for an eccentric shape gear, and in grinding by pivot line you are not assured of covering that point. There is a process used by some manufacturers—take it in carbonized work—of carbonizing and then broaching the finished broach after the carbonizing before the final treatment. But that has its disadvantages. I had a report from one company who had tried out both processes, using the same materials in heat treating, and it worked out that they had from two to three per cent. less loss in their gears from working from the outside diameter of the shaft over the grinding from the pitch line, and it was primarily to bring out that discussion and find out what the experience of the engineer had been, and let them, if they will, instruct the committee as to what standard shall be adopted.

MR. FERGUSSON: We have tried both. We are at present using the outside diameter of the spline shaft and not grinding out the hole. We have adopted that and it gives some nice results. We thought we would try to alternate it and made some the other way, but the manufacturing end of our business claimed that it was too difficult a proposition for them to set up the gear by the pitch line and grind a true hole, and we couldn't find a great deal of difference in the results of the sets of gears that we made in each way, and the manufacturing end of the business decided that it was a good deal more expensive to grind the hole in the gear, and so we fell back on the old system in leaving the hole as it was and grinding the outside of the shaft.

MR. SWEET: Regarding the locating on the pitch line, we have had some experience along that line. About twelve years ago I spent three weeks at the Pope Manufacturing Company. Mr. Rice attempted to grind the box and holes of large bevel gears by locating on the pitch line, and the results were not very satisfactory. But when they began to locate at the bottom of the space, then the result is much better. We find that it is better to locate at the bottom of the space and then we don't enter into the straightening of the teeth. We go right to the bottom of the space, and the general result is much better.

MR. VINCENT: A thought occurs to me along that line: wouldn't it be possible to adopt a standard set of broaches that would be,—that would make it possible to use either practice,—in other words, the broaches to be large enough to give clearance where the hole is ground out and simply make the outside of the spline enough smaller for clearance, or where the manufacturer preferred to make the spline enough larger to grind. It is just a thought that might be worthy of discussion.

MR. DAVIS: I believe it would be possible to establish what has been recommended on the subject of broaches. Following the line of the suggestion of Mr. Vincent, I think it would be possible to adopt the standard as suggested by the committee and that that could be finished either way, and it would be a question of results on shaft fittings, while your broaches would remain constant.

Mr. Sweet: It would seem to me wise to leave that point open. It would seem too bad to close the door upon the other scheme. I believe it will serve more of us if we had suggestions along both lines. In other words, don't close the door. For I think many of us will resort to what we need anyway, but we would like to follow the standard as well as possible.

Mr. Foljambe: I move the report of the committee be adopted. Seconded. Carried.

Discussing Magneto Standards

President: We have from two members in different parts of the room a suggestion that one of our committees get busy on the magneto standard; the base height of dowels and coupling distances from the gear; center from the drive and spark device will have to be considered. It seems to me this is a very good idea, and I believe we have men among our Standards Committee who can handle this matter. If not, the council will see to it that it is taken care of,—unless there is some objection. Of course, I know that there are some standards now, and it only remains to investigate them and put them in our book where they can be seen. I think no further action is necessary.

Mr. Slade: I would like to suggest while on question of standardization that some elements which will be elements of motor speed, whereby the spark advance can be eliminated will be a point that the committee can take up. There are not any magnetos on the market now which are applicable to motors having a very wide range of speed, without an automatic spark advance. I think that is one phase of the subject that the committee should consider.

Mr. Muskovics: The point is a very sore point with practically every manufacturer of magnetos;—the matter of couplings and base height is a very serious matter. I think that the suggestion that came from the other side of the house came from a magneto manufacturer that has over seventeen thousand models. And I know another one that has just about as many, and their troubles are very great. I think that there is nothing in the line of standards that would help much more than this one point.

Mr. Von Rottweiler: I think that the height of the magneto base is the most serious thing of all. Every magneto takes a different size. A man couldn't make any pattern where the arm would be interchangeable. If I have a four by four and a half motor that I sell in thousand lots, and a man says I want an arm handle on it, and that pattern is made with a fair amount of side play; and on the next order a man will want something different and I have to change my pattern.

Mr. Muskovics: The point that is most important is the distance from the drive outward. We have always got the German height. We all had to follow them. But it is the other distances. I think Mr. Whitman could make some remarks on that that would be interesting. He has got about 150 models.

Discussion on Sheet Metals Division

Mr. Skemp: It is absolutely impossible to recommend the adoption of any particular class of steel for any particular part of an automobile. About all we felt we could do was to put before the users of the sheet metal the various grades that were ordinarily produced, describing as briefly as possible the finishes that were usually supplied and indicating the results that might be expected from the use of those finishes.

We are confronted, of course, by the fact that each branch of the sheet metal industry uses its own particular gauge. Some use the United States Standard gauge, and others the Birmingham Wire Gauge. We don't think it was within our jurisdiction to recommend the adoption of any special gauge. Each of these gauges has its equivalents in thousandths of an inch, and we feel if specifications were written up in thousandths of an inch, and if the specifications when so written are made to conform as closely as possible to one of the gauges of the department or branch to which the specifications refer, it will be much more easy, of course, to obtain stock sizes.

I would like to say, in regard to the finish of sheet steel, that there is a mistaken impression in the minds of most users as to the results they secure by the use of pickled and higher cold rolled material. I would say that sometimes it is necessary for that material to be used. But whenever any process involves the heating of the material before it is pressed or formed, the necessity for the pickling and cold rolling is done away with and the expense of that treatment is absolutely useless expense.

The cheapest grade,—the blue annealed sheets—as far as the steel is concerned is the best. The finishing processes really add nothing to the value of the steel. They really detract from the steel and wherever it is possible to use the cheaper product,—the blue annealed product—without injuring the dies or stamps, that product will give the best results.

In regard to the question of uniformity of thickness: That is a matter that has been dealt with with great care. It is an absolute impossibility in the manufacture of hot and cold material to preserve a uniform thickness throughout the sheets. There is a constant changing in the contour of the rolls owing to expansions by heat,—from slight inequalities in the temperature of the steel. And it is necessary to allow for liberal tolerance in regard to these matters. Your committee has indicated what may be considered as reasonable variations in the thickness of hot rolled material.

President: I feel that this report is one that might well go into our data book as it stands. It is not done, and it will be a long time until it is done. But it is a start in the right direction and is extremely instructive and ought to be helpful to anyone contemplating the using of sheet metal or the ordering of it.

Mr. Hussey: I make a motion that it be adopted. Seconded. Carried.

The Springs Division Report Discussion

Mr. Bergmann: You all have copies of the report of the Springs Division, and you will notice on the last page that there is some discussion regarding the size recommended on center bolts, as well as the standard thread which we suggest as ¼-inch pipe, requested by the committee.

Mr. Holsman: I was looking over this paper this morning;—I may have gotten hold of the wrong paper, but as I remember I saw the A. L. A. M. Standard thread was specified for bolts. I don't just see where that is now. I would like to ask why A. L. A. M. Standard threads should be used for bolts and springs?

President: There was one suggestion made to the Standards Committee and adopted by the Standards Committee in relation to flexibility.

Mr. Landau: On the subject of springs, I would like to make a few remarks relative to nomenclature, especially "flexibility." The word "flexibility" is used by the sub-committee and its correctness applies to the semi-elliptic type of springs. The word "flexibility" is used abroad to-day as denoting the deflecting per 100 kilometers. But they also use the same word in a little different form. They place fifty pounds upon the quarter section and call the deflection the flexibility of the quarter portion. The advantage of stating flexibility in that method is very evident to one having to calculate it, because by adding the flexibility of half elliptic per 100 pounds to the flexibility of quarter elliptic per 50 pounds, you get the total flexibility of the three-quarter spring. I would suggest that the term flexibility be as stated in the report and add the flexibility of the quarter for the deflection of fifty pounds on the quarter portion.

In reference to nomenclature, there seems to be some inconsistencies in the definitions. First we have A, known as half elliptic. Under B, it says, "elliptic; consists of: top half, elliptic; bottom half, elliptic." It is evident from that that Spring B must be composed of two full elliptic springs. In other words, it is twice as many springs as is shown there.

In reference to C, called the scroll elliptic, I am inclined to believe if this was placed in our data books there might be some misconception because there is a type of spring that is used,—particularly abroad,—and will be in this country, known as the scroll, which is practically the same as that shown, except that the shackle of the scroll portions has the scroll portions independent.

In reference to F, the definition of the three-quarter elliptic, there are some inconsistencies at the bottom there where it says joined at both ends by bolts. From the sketch it is evident there are not two bolts. Therefore I would like to see the word "bolts" changed to "bolt."

In regard to G, we have a form of spring shown which is very largely used to-day in horse-drawn vehicles. But upon investigation—when I received this report—I might as well say that Mr. W. H. Son, who is on this committee, asked me to take care of some of this for him, and he gave me at my disposal quite a lot of information, regarding quite a lot of the springs that they have been supplying. There is only one manufacturer who supplied the type G for the automobile in the last seven years; if there are any more, I would like to know it, and I have never seen it used on an automobile except once. I would, therefore, suggest that type G is practically obsolete as far as the automobile is concerned, and I don't see that we need a definition here.

On the subject of springs shown in type H, known as the three-point suspension. It has long been known as a form of platform spring. It would be better to call it a three-quarter platform, because the term "platform" has been very common. Therefore, I suggest that we adopt the name of three-quarter platform for the so-called three-point suspension.

About that four-point suspension, I must state I have never seen it used in an automobile.

In connection with the recommendations on page 5 for ordering springs, there are several places I wish to call attention to. I might stop here for a moment and digress from the subject by saying that I think it would be advisable for the committee to add to this paper sketches indicating the dimensions to be followed in ordering, because I find that the men who are working in the spring plants cannot name certain parts without you show a sketch indicating what you mean on account of the variety of sketches.

Under A we have, "Give type of springs desired. Exercise great care to select types suited for purposes to which put." I would like to have the committee recommend the type for suitable purposes. In other words, how can we exercise care unless we know what type we are going to use. It seems that the committee should exercise care in recommending a type.

In B it says, "Specify material." There is no objection to that as long as the material is specified in a proper sort of way.

In C there is some misprint. It says, "Specify width of spring either by 000 or ¼ inch." I think the committee intends that to mean, specify width of spring leaves in inches. Or if it intends that to mean thickness, it should be inches or the standard gauge. Otherwise, C is inconsistent with itself.

The next subject which is really of importance, and is not quite so academic as some of the others I have mentioned, is the question of standard sizes and width of steel. The committee recommends inch and a quarter for pleasure cars. I don't know, but I would like to ask Mr. Tuthill if he considers inch and a quarter a standard size for a pleasure car. Inch and a quarter and inch and a half are not really standard size for pleasure cars. They are special sizes. I venture the opinion, and I rather think I am right, that our mill don't carry those in stock as regular sizes for an automobile. The three-inch size recommended in the same place is not really used in pleasure cars. It may be put down as commercial pleasure car size,—such as the large sight-seeing wagons.

In D,—"Number of leaves in gauge to be left to the spring maker." I don't know what that means,—unless the word "in" should be changed to "and."

Referring to E, it says, "Give offset, stating length on both ends on straight line between holes in brackets. This should be given on all half elliptics." I prefer there myself to show a sketch, because we don't know what the half length of a spring is; sometimes it is not a half length; that is, in the offset spring there are two halves, which are equal to a whole, but not halves in themselves.

In the three-quarter scroll, bottom half, the committee says, "Give distance on straight line from hole of front bracket rear spring to point on frame vertical to rear axle." I would like to know if the axle is going to be parallel to the floor. That seems to be inconsistent. I would recommend that the committee in this particular case shall be requested to make a diagrammatic sketch, indicating clearly what they mean. I venture to state if this paragraph is read carefully, almost every member in the room will give a different opinion.

Getting down to the latter part of it on the same page it says, "Give distance from spring seat to spring seat, or bracket holding upper quarter." That is not really what the committee means, I believe, and a sketch here would be very advisable. In the case of a three-quarter scroll the distance is usually given from the bottom,—the short space of the half elliptic. That is not stated by this definition. At least it wouldn't be considered so by a spring maker.

I would like to ask the committee what they mean,—"Do not give depth of scroll."

Commenting on some of the things that are mentioned here that are excellent,—for instance, "Give clearance under load with passengers, in front of two nearest striking points and position relative to rear axle,"—I do believe, in taking the entire report of the committee,—this one paragraph is really the most important, taken every which way. We have complaints in regard to springs, from this feature. It is not the spring makers' fault. It is the fault of the customer in not giving the clearance in front of the two nearest striking points. I imagine it has cost every spring maker a good many thousands of dollars a year to get this little information. If it is not stated, you are likely to have the spring maker make a very heavy spring, or he is likely to get it too light. But he can make them right, and make them cheaper, if you give him the right information in the first instance.

Next, we have, "Give center of load front relative to front axle" and "Give center of load rear relative to rear axle." Those two points there I want to say that I don't personally understand what they mean. I would like the committee to make it more definite.

It says, "State whether spring takes driving." I would suggest that they add "before breaking." Because the stress of the main leaf changes very rapidly. If it does take breaking, the number of clips applied to the spring will vary if the breaking in must be taken on the spring. "Give number of passengers," I think is very advisable.

There is one point that was discussed at the recent meeting of the Society here,—that is the truck situation. Everybody is interested in truck spring design. It says here, "On trucks give merchandise load." I would simply add at present that it is desirable for several reasons,—the truck designer would especially appreciate it, if you were going to supply cars to a certain concern and you know any of the service,—I would say give the merchandise load and also the nature of that load. If you are going to supply one hundred trucks, we could give you better springs if you can give the nature of that load. It doesn't cost any more to you to specify it, and you will get a better spring for less money. If you have got to carry flour, you will have to have a little different spring than to carry beer.

On the subject of flexibility, I have expressed myself already.

Next we come to the features to be left to the spring maker. It says, "Eye up or down, in or out." When I first returned to this country after having served my apprenticeship with spring makers abroad, and I came home and found expressed in and out. And frequently what was meant by "in" was "out." I would suggest that here is a very important point for the committee to indicate by sketch what they mean by eyes up and down, and in and out. While it is perfectly clear to the spring maker, it is not to the spring user. There are conditions where the designer will know much better which to use. Of course, he can leave it to the spring maker in certain cases, but there are cases in which he cannot leave it to him.

I don't know what the committee means by "spacing of leaves." But I suppose it is the pitch of leaves. In which case, it is commonly expressed in technical literature, as the pitch of the leaves, rather than the spacing of leaves. The committee has to "state whether shackles are under compression or tension and length of shackle used." I don't know whether it is essential to know whether the shackles are under compression or tension.

I am not prepared to express myself on the subject of bushings. I will say that with gas-hardened bolts, bronze is desirable, although the question of steel bushing,—I don't know.

In connection with eyes on pleasure car springs; for reasons that I cannot express briefly, I am sorry to state that I cannot agree with the committee on this subject at all. It is impossible to specify these on theoretical grounds and on practical grounds we have got to wrap two leaves around the eye, and the eye we have here is simply the common eye, and you will find that they have three springs wrapped round the eye. And there are good reasons for it. That is, the clearance upon the successive wrappings of leaves, which are even more important; many of the engineers say that the eye wrapped around the faces have no clearance. With one engineer he wouldn't allow us to separately open the eye a quarter of an inch to allow for the location, and it would be advisable for the committee to add a certain opening that must be kept, so the engineer will not insist on the spring maker giving him what is a close wrapper, which is a physical impossibility, because it doesn't work that way unless you introduce severe stress on the second bolt. I would, therefore, suggest that the idea of one leaf be left entirely out, or left to the spring maker.

In regard to the width of bar, the committee states that there are zero tolerance and plus tolerance. Zero tolerance means the size of the hole and the size of the bolt are absolutely the same.

Discussion on Uniform Gear Shift Position

PRESIDENT: The next matter is the report of the chairman of the Miscellaneous Committee.

MR. BERGMANN: We have several questions to take up. The first is the gear shift position. The matter of the gear shift has been referred to the members of the committee, and we have submitted sketches with the three- and four-speed arrangement. Naturally this is an interesting subject and I would like to hear from the members in regard to their choice.

PRESIDENT: It is considered possible by the Standards Committee to put in our data book several gear shift gates. This may do something toward keeping the engineers or draftsmen from designing new ones. I don't know that there are any more new ones, but possibly there are. There is no doubt that all cannot concentrate on one, but if they could concentrate on two or three, it is certainly something, and so this subject is before you from this point of view.

MR. RICKER: I would like to repeat some of Mr. Camper's points that he brought up; they are, as shown here, that the high speed should always be at the back, and that it was advisable with this combination to have the emergency brake a pull lever. In that way, a man in a hurry to stop would not have the opportunity of grabbing hold of his speed lever instead of the brake, because the high speed lever would probably be at high speed, and the brake lever would be entirely isolated at the forepart of the quadrant.

The other point that he brought out was that with a four-speed gear box you invariably start on second speed, so that you really have the same conditions with four-speed gear box that you have with three-speed gear box.

MR. MYERS: I would like to call attention to the fact that there are two, of course, two styles of gear box using four gears; one in which the speeds are progressive, and the other in which the high gear is a gear up from the direct drive. In connection with that, the fact that on the last mentioned type of box, it is sometimes quite important to have the first gear and the reverse directly opposite one another, so that they can be readily used in traffic. The fourth gear is not as a rule used in traffic or in the city, but when you get out on a clear road it is, and I think that sketch should be included; and the fourth should be shown, there being three slides on the outside. I had a little experience with a gear box of that kind and where the reverse is put, as it is here, on the inside, it would be much more convenient to have No. 1 and the reverse in the same side; probably the fourth outside.

MR. MOSKOVICS: It would seem to those, who, like myself, want to go and borrow one of their friend's cars, that it is an embarrassment to find the low and high speed levers on different sides. It would seem that the committee could recommend a position of the low and high speed. It would make some advance in that line, and it would assist some of us that use so many different cars.

MR. RICKER: In connection with putting the high speed on the outside, one point was brought up, and that is with inside levers on a foredoor gear it is most convenient to have the high gear as close to the outside as possible so as not to interfere with the comfort of the driver.

MR. COFFIN: It is just as easy for the designer to adopt one form of lay-out as to adopt a diversified lay-out, a different lay-out, because in nearly all sliding gear boxes, there are nearly always two or three slides used whether the high or low speed levers are put on the inside or the outside, according to the designer's selection. The idea in laying them out as they are laid out is that the form of the high and low are all the same in the three and four gear boxes. Almost invariably a four-speed box is stated on second gear, which on the four-speed box is exactly the same position as is first speed on the three-speed box. Therefore, the movements that the driver goes through in any of these designs are exactly the same. Had that been covered? The position of the high-speed lever at the rear places it in an out-of-the-way position at any time or almost invariably at the time that the emergency brake lever is to be reached in a hurry. In other words, there is no possibility, even for an amateur driver, of becoming confused and getting hold of the speed lever instead of the brake, and that happens very frequently. He will grab the gear shift lever and pull it back into some other speed and then get completely rattled; whereas if they only had one lever in front of them and that a brake lever there would be very much less chance to get into trouble.

Standardizing Steel Flywheels

MR. BERGMANN: Another subject that was referred to the Miscellaneous Division was that of screw standard. (Mr. Bergmann here read the proposed changes.)

PRESIDENT: That matter has been very carefully discussed by the Standards Committee and they believe that it should be acted upon at once. They further brought up the question of changing the name to the S. A. E. standard.

MR. COFFIN: There will be no objection, I believe, to the standards becoming known as S. A. E. Standards. The A. L. A. M., had turned over to this society all the work connected with such matters as this, and the name even of the organization once known as the A. L. A. M. has been dropped, and it would seem to me to be highly desirable to make these standards known as S. A. E. Standards. This would prevent any confusion which might arise in connection with any future work alone this line that we might want to do. I think that is all, from the committee's standpoint.

MR. FOLJAMBE: I move that the suggestion of the committee that these standards be called S. A. E. Standards be adopted. Seconded. Carried.

MR. C. E. DAVIS: In connection with that, does that cover the necessary publicity in connection with people who are designating these in their catalogs?

PRESIDENT: The question now is as to the adoption of the modification and extension of sizes. A motion is in order. The A. L. A. M. dimensions are now in the data books. The changes are very slight, and they are not in the body of the thread, so that there will be no serious complication. It is a matter of head size, and it amounts to nothing from the engineers' standpoint.

MR. BIRDSALL: I move the alterations and extensions be adopted. Seconded. Carried.

Discussion on Tolerance of Spark Plugs

MR. BERGMANN: The next question is the tolerance of spark plugs. The consensus of opinion seems to be from plus zero to minus .003. Is there any discussion on that?

MR. FERGUSSON: I think I suggested that. I had a lot of trouble with different size spark plugs that they were making. And we wanted a pretty good fit, so I suggested .003 for the minus; and nothing over for the spark plug size. I don't think that is too small a tolerance to allow; .003 over size hole in the cylinder and .003 in the plug is .006, and it don't work well.

PRESIDENT: Is it the wish of the members that this refinement be adopted and the tolerance be plus zero, minus .003?

MR. BIRDSALL: I move that be adopted. Seconded. Carried.

MR. BERGMANN: The next question is the standards of the rod and yoke ends as submitted by Billings & Spencer. This work has been gone over very thoroughly by the committee and has been accepted unanimously.

MR. BIRDSALL: I would like to make a motion that on any of the former A. L. A. M. standards, when they are refined by this Society, that the name is changed to S. A. E. standards. Seconded. Carried.

PRESIDENT: The question is now on the adoption of the rod ends, that is, the recommendation of the rod ends and the subsequent printing in our data books.

MR. H. I. POPE: I would like to make a motion that the rod ends be accepted and put in the note book in accordance with the recommendation of the committee. Seconded. Carried.

MR. BERGMANN: The committee wishes to announce that the title used in page 188 in the Transactions and known as Specification No. 26 for Oils, to change the name from Automobile Lubricating Oil, to Automobile Engine Lubricating Oil. I would like to have the members express their opinions on the vehicle taxation basis. The committee has asked me to announce that.

PRESIDENT: The question of automobile taxation came up last summer, and a number of us, to my personal knowledge, have been trying to find a formula that would fit all road users—horses as well as motors. The question of the old formula suggested itself—MV^2. And in attempting to apply that, it was found that V^2 was too big an element; that the figures went up out of sight. Then MV was tried, and MV seemed to fit pretty well, and then some attempt was made to find for what reason we should use the V, and quite a bit of correspondence was had with the railroads as to whether tracks wore out in proportion to speed or in proportion to load. It was stated by Mr. Buckwalter that it certainly was not speed and surely not the square of the speed:—that it was somewhere between V and V^2—probably near the V. The Michigan Central, I think it was, stated it was probably near the V. So I wish some of the members would set their wits to working to try and find a formula that we may safely hand to our law makers. Our law makers are coming to us pretty soon, and ask us how to tax all users of roads. With these thoughts in mind, the matter is open for discussion. Are there any thoughts?

MR. HAYNES: I think a certain amount of experimental data would have to be obtained first. The formulas would be of no value unless backed up by data that had been demonstrated by actual experiment, before it could be endorsed by the Society and before it would be a proper subject for consideration.

Standardization Steel Flywheels

MR. BERGMANN: Can I hear from the members regarding their views in connection with steel flywheels.

PRESIDENT: A very interesting matter has been broached by one of the large steel companies. They now say they are making some steel flywheels and welcome and ask our co-operation and ask that we give them sufficient data so that by some means they may propose a standard or get up a standard lot of steel flywheels which are forged. They get right down to nearly cast-iron price with their very rapid method of forging, which amounts to nothing short of spinning. They spin up the steel just as you spin up pottery.

MR. FERGUSSON: We have used for two years now a forged steel flywheel on our largest size engine. It has quite a large diameter. We are afraid of cast iron, and we have got a forged steel wheel there. And it works just as well, if not better. It gives about the same co-efficient as on the cast iron. In fact, it makes a much better wheel. The thing is in perfect balance. There are no porous places in the forged wheel. It is a balanced wheel and requires very little attention.

MR. HORNING: It has recently been our pleasure to go into the matter of steel flywheels with the steel company, rather than that they went into the question with us. And the first statement was that the cost of the wheel would be approximately what cast iron would be. We consented to have them make a standard wheel; it seemed that they had their specifications and standards at their place of manufacture. They submitted these, and we found that the cost of the wheel to us rough was more than the finished flywheel in cast iron. Now, I assume in submitting the figures that they gave us a wheel which they were producing in large quantities. And I had several calls from the representative, and he at last had to give up the job and admit that the steel flywheel in the rough would cost as much as the finished flywheel in cast iron.

It is only a question of safety in flywheels that we have found in our experience that the user looks at in flywheels. Where flywheels are cast with blades for producing the draught, the strings which fit on the relief are a constant source of danger. We have one experience with one flywheel which was being used at the time by a manufacturer to test out the engine. He was making a test on it, and it broke. An examination of the break showed that it was a casting string. In connection with the heat produced by the break and the heat due to centrifugal force, it was too much for the string and it separated. I recently heard of another case of a very well known car that it did the same thing. Therefore our experience with vane flywheels, as we call it, unless particular pains are paid to the relief casting strings, is that there is a great source of danger, there, but in the flywheel with the usual construction of solid web you can use a section down to 3-8 of an inch with safety.

MR. VINCENT: There are so many engineers right here assembled that are undoubtedly building motors, and if this one company wants to adopt a standard flywheel, and a certain motor has a compression of 65 or 70 pounds,—the next man has that same motor of the same bore and stroke with a different compression entirely. Now, in order to have a higher compression you need more flywheel energy and I think too many different sizes of flywheels would be needed to meet the demand, and I think a standard in that is out of the question because there are many different sizes of motors and so many different compressions in those motors that I think there would be so many different flywheels needed that it would be impossible to come down to a standard in flywheel design.

MR. COFFIN: I don't believe that it is possible to carry the idea of standards into a matter like a flywheel, which is so intimately interwoven with the vital parts of the construction. You have the gear box behind and the motor in front,—if you standardize the flywheel, I don't believe there will be very much limit to what you might not do. I think the things we should attempt to make standard are the things that might just as well be standard as otherwise. We have tried to avoid the standardization of any part which, or upon which the designer may legitimately exercise a reasonable ingenuity or ability. Such matters as rod ends and carbureter connections and so forth,—upon such matters as that I don't believe there is any engineer in the room who would care to spend very long in instructing some draftsman how they should be made. Therefore they may be incorporated in tables and that detail removed from our attention, to let us concentrate on things that are more important.

Paper on Aluminum Castings

PRESIDENT: One member is here who has come a long way to present this paper, Mr. Gillett.

MR. GILLETT: The paper has been printed and anybody that is particularly interested I hope will read it. The proposition that I want to bring out in this is that with the increasing number of aluminum castings the factories are requested to make they run up against very great difficulties, due to design and to patent constructions. The vital point of the whole matter,—the one that concerns not only the manufacture but the price and delivery—is in getting together with the factory at the right time. If the designing engineer would take these matters up with his factory and get their ideas on it and get their pattern makers in touch with the factory, it would aid a great deal.

I have a few samples here showing some of the defects due to faulty design, which perhaps I haven't time to pass around, but anyone that is interested can see them. They are labelled with the numbers corresponding to the reference in the paper. The whole proposition,—the best design of aluminum castings—is one of uniform section as near as possible. Here are two samples. Those are parts of the same castings. This one is well designed; that is, there is no sudden great changing of section. This one you see has a crack in there. You have large sections here next to small sections. The small sections freeze first; the result is a crack. The losses on this proposition were far too much. There is no reason why they all should not have been made solid.

One other point is the design of the casting in such a manner to allow cold pouring. Cold pouring gives you fine crystals, well interlocked, and a strong nut, because the freezing takes place equally. If you have exceptionally thin portions in your casting, you have got to pour hot in order to fill your castings. The effect of hot pouring is shown by this bunch of test parts here, which corresponds to that shown on page 4, showing how the tensile strength falls off extremely rapidly with the increase in pouring temperature. This bunch of test bars shows a very good tensile strength, and at the hot end,—these were all poured from the same batch of metal,—at the hot end you get a very weak bottom,—very rough surface. If you can take up with the factory while your new designs are in your mind and in your draftsman's hands these points with those that handle the manufacturing of the material, I think you will serve your own best interest, and I think you must remember that these things we cannot change;—the design is up to the designer, and perhaps half of our factory troubles are traceable directly to the design and construction of the pattern.

Long Addendum Gears—Oversize Piston Standards

PRESIDENT: Mr. Weaver is here with a very good paper on Long Addendum Gears. The long addendum gear seems to be of greater value on one particular place, and that is the bevel driving gears, on the rear axle. There was quite a discussion the other night in regard to noise. This seems to get away from it to a certain extent. And it also provides a much stronger form of outlay. That is the main things to be said in favor of it. It does not require any special outlays, except possibly gauges for making it, most of the bevel gears being cut on Gleason machines.

There are one or two errors or corrections that might be made. On the second page down near the bottom, it says "For 20 degree pressure angle multiply the circular pitch by .5927 and .4037 respectively for the pinion and gear." It should be .4073. And on the next page, the sixth line from the top, it isn't clear. It reads B minus C, and it should read "line BC." There isn't any minus in there at all. And down a little further, there is a rather complicated formula given. It can be simplified greatly by multiplying the circular thickness by 28.648 and dividing by the radius. It is a matter of cancellation, and of course it is not printed in such a way that it would be very clear.

I have also added tables for the thickness for 4 1-2 degrees. For any one that wants to do a little experimental work it will merely furnish a little data to work from that has been valuable.

PRESIDENT: The next paper is by James N. Heald on "Oversize Standards for Pistons and Rings." This paper will not be read. What is the idea of the members present as to the possibility of doing something toward standardizing oversize pistons?

MR. COFFIN: Throughout the manufacturing season, there are always a certain percentage of cylinders faulty, through oversize dimensions. A cylinder is a pretty expensive portion of the car construction and naturally there is considerable regret in the manufacturing department with having a scrap pile of cylinders charge to their department. Our own practice is to save up cylinders which were oversize, and at the end of the season bring forth a series of motors, using these cylinders,—properly numbered, so that the service department can keep track of them,—and regrind them to a certain definite oversize. This saves a great deal of money.

PRESIDENT: Have you any thoughts as to taking action on that matter among the committee?

MR. COFFIN: It would seem very simple to adopt certain dimensions for oversize dimensions and for reboring of old cylinders for which it might be necessary to get larger pistons. We might go up by steps of .005 or hundredths of an inch or something of that sort.

PRESIDENT: At the bottom of page 8, in this paper it says: (Here the president read all of that part of the paper on pages 8 and 9, under the heading "What The Oversize Standards Should Be.") There is a suggestion of two oversize standards. Is it something that you would like to have the Standards Committee take up?

MR. FOLJAMBE: I move that the Standards Committee take up this matter as suggested in this paper. Seconded. Carried.

PRESIDENT: Mr. Clayden, do you know whether or not European manufacturers have made any attempt to carry oversize pistons?

MR. CLAYDEN: I don't know definitely that any of them are doing it at present. I know that they have in the past. It is rarely difficult to obtain an oversize piston.

Reducing the Number of Lock Washer Sizes

PRESIDENT: It is apparent from some of the statements made during the Standards Committee meeting that the various engineers have all taken a crack at lock washer designing. Now, it is a long jump from three or four hundred sizes of washers down to sixteen. It seems like a very radical measure perhaps. You will notice the typewritten list shows only sixteen sizes of lock washers, all of square sections, and that the square section is practically the short diameter of the U. S. nut and the long diameter of the A. L. A. M. nut. So it seems it has logic back of it. Is there anything that is objectionable in that? Is the washer too heavy, and is the proportion of 3/4 height to 1 width wise? The objection may be raised that the lock washer may be a little thick. Of course that will help its holding power, and that little is not very much. There is no question but what if sixteen sizes can be used for all purposes or up to inch and half bolts that the cost of lock washers will not increase—it may diminish after the trade becomes adjusted. There has been raised in committee the alternative for the 3/16 bolt, instead of 5/16 use 5/64; for one quarter, instead of 5/64 use 3/32. That is an increase of a sixty-fourth only in a few cases. Those small things seem to be the only question raised in committee.

MR HINKLEY: It seems to me that the suggestion about the smaller sizes is good. For instance, 3/16 or quarter-inch sizes are heavier than we will be able to use in certain places. It seems to me that the thickness is running out of keeping with the width. You take any parts designed where the property of appearance enters into it very strongly, it seems to me that we could get a slightly thinner washer that will serve the purpose better, due to the fact that a thinner washer will give a better locking property.

MR. SEYMOUR: In regard to that matter, one of the trunk lines in the country was using a washer 3/8 wide. They decided the washers did not have enough spring pressure. They did not want to spend more money for their washers and raised the question whether another shape wouldn't give the result. The shape of their washers was 3/8 x 1/4; in other words, the cross section which should be the same in a washer 5/16 in. square. They had some sections made which were 5/16 square. And they subjected the washers they had been using and the new type to a pressure test. They found the 3/8 x 1/4 gave a pressure of some 1800 pounds and the 5/16 gave a pressure of 2800 pounds; they have been making the square washers since 1885, and this washer in service will give just as good results as a washer whose height is one-half its width. In this list the outside diameter of the washer corresponds with the long diameter of the A. L. A. M. nut and practically corresponds to the short diameter of the U. S. standard nut. In other words, it comes as near a perfect appearance as you could get. The square gives the proper results as to resiliency. These sizes have all been used or ones the same form, so that we can stand behind each section and guarantee its efficiency. The same difference in shape has been made to accommodate the A. L. A. M. and the U. S. nuts.

MR. HART: I think that the Lock Washer Committee have cut the engineers down to too small variations. The engineers have designed over three hundred variations. I think I must give the automobile engineers credit for knowing the thickness of washers that they want in connection with their cars. Now, I appreciate the advantage of cutting down this list to sixteen if we possibly can. Take the 5/16 washer. I do not believe it can be used in all parts of the car. I do not believe that you can use it on brass or aluminum as well as you can cast iron. The locking power would be too great on the aluminum and brass; if that part had been taken off you would only destroy the lower backing, where the 5/16 x 1/8 could be used, very successfully with cast iron or steel. I therefore would favor giving the automobile engineers a greater variety to allow them a greater selection, so that they can choose a washer to fit the bolt, according as the washer is going to come in contact with either brass, aluminum or steel.

It seems that on 7/16 washer Mr. Seymour has remarked that there is only a slight variation of thickness from what the present automobile manufacturers are using to-day. I would like to say that for the past two years the automobile people have come together and have agreed to use and are using each others' washers more than they were four years ago. I can name thirty-five concerns to-day that practically adopted the 3/16 x 1/16, 1/8 x 3/32. I don't think it is necessary that we should hold to the square section, 3/8 x 3/8, 7/16. I would recommend 11/64 x 3/8, 1/2.—11/64 x 3/8, 9/16. I think a most satisfactory washer could be used there by using 7/32. Take the 11/16, 3/4 and 7/8, it really seems to me that, although very few of those three sizes are used to-day in connection with the pleasure car, we hope that they will use more of them in connection with trucks. It seems to me that the Lock Washer Committee should give the automobile engineers, say, three variations of size on 1/16 washer and three variations on the quarter-inch; three variations on 5/16 and ⅜, keeping, of course, the standard lock washers as small as possible. You take the 5/16 washer; if they should prove of use, ⅛ x 3/32; this washer is almost too heavy to put in connection with any part where there is any brass. There is a great deal of manufacture, and it seems that on the last four sizes beginning with quarter-inch to ⅝, they have given such slight choice. Taking into consideration the lock washer manufacturers are carrying such tremendous variations of steel that it seems that these four sizes should be brought in, and the majority of automobile makers are using them to-day. That would be 5/32 x ⅛ washer. I would like to change that size on half inch—make that 11/64; change 5/16 to 11/32 x ⅝.

I think all the lock washer manufacturers to-day are practically manufacturing every size that the other has done. And it has been very difficult to get one engineer to change over. For instance, if you tried to get him to use 8/32, which you were furnishing to fifteen others, he absolutely refused to do it. They had designed a certain washer, and they considered it best for the place they were going to use it. There are many of them using two or three sizes on the 5/16, claiming that they have to on account of the metal they are using. I don't see but what the engineers would like to get all the locking power they can. They would like to use 5/16 washer, if they believed it would give greater locking power, than this ⅛ x 1/16, but the metal backing will not allow them to use it.

Mr. Seymour: That point against aluminum and against brass raises a point that has been argued by a good many of the automobile engineers, but I will state here that the largest users of lock washers use a 5/16 washer and use it against aluminum with no protection between the lock washer and the aluminum. Now, if you are going to look at securing good locking power against aluminum you have got to have a washer which is strong enough to take a bite on the nut. If you put a very thin steel washer between the nut lock and the aluminum it will not take as good a hold as the thicker washer, and the thick washer will not break off the aluminum. Now, the manufacturer to whom I referred is to-day using sections from a quarter and up larger in each case than the sections recommended by this committee. They have been using them for three years and the use has been very satisfactory. There was a good deal of question raised about three years ago regarding the use of thin washers. We tried them out ourselves and tried them out in comparison with other washers, and our experience was that they did not hold. We wanted to have an unprejudiced opinion on the matter, so we wrote to R. W. Hunt and Company in Chicago, asking them to make a test on washers. They used washers 3/8 x 1/16 and 3/16 square in their tests. They tested them on nuts and counter pins. I have a result of the test here before me. In the case of the washer 3/8 wide by 1/16 in height, they secured looseness after an average number of revolutions of 60,675; with the square washer it took 87,800; and in the installed nut and counter pin that created between fifty and eighty thousand vibrations, and the result showed that the effect upon the square washer was practically zero.

Mr. Hart: The practice of using a steel washer in connection with lock washers is quite old; but on this Lock Washer Committee we are trying to get away from sizes; you are introducing and asking the automobile manufacturer to use the proper weight washer that will dig into the head of the screw. I don't agree with Mr. Seymour that a washer made from 1/8 x 1/16 steel would not mar the head. I don't believe that all the engineers can get along with these washers. Mr. Seymour speaks of one concern using the size he recommends; the sizes I recommend are being used to-day by more than fifteen concerns and the largest machine makers of this country.

Mr. Birdsall: I agree with Mr. Hart that we need two thicknesses, although I recognize fully Mr. Seymour's remarks on the subject. It is my experience that the square washer is too strong on an aluminum backing. The only question is whether we can get a lighter washer that will bite into and also not ruin the aluminum backing after it is taken down three or four times in the repair shop. And I think there is enough of us here who have had experience with lock washers, so that we can determine now and incorporate in our suggestion to the committee the thickness of the lighter washer. My opinion is that they should be either two-thirds or three-fourths of the thickness of the square washer.

Mr. VonRottweiler: Now, here is a washer on this table, 5/32 inch thick; for instance, on 5/8 bolt,—if I wanted to use it against aluminum, I wouldn't care to use that; there would be too much pressure against the aluminum; that would be too much because you would tear the aluminum right out. You just dig a hole right in the aluminum, just by taking it off once.

Mr. Trask: We use a great many quarter twenty screws in a certain part of our car, under which we want a light washer, that is, about right for a thickness of not more than perhaps 5/32 of the thread; that is, threaded aluminum. Now, under those conditions it seems to me that 5/64 square is altogether too severe on threads of that length. Consequently, I think we ought certainly to have a lighter washer, perhaps two-thirds the width of the stock.

Mr. Birdsall: In getting at that 2/3 I think we had better hear from the gentlemen who dress the steel and see whether there is any commercial difficulties in the way of dividing these fractions by three; and whether it is possible to adapt the thickness to the practice of the steel makers.

Mr Bugie: It only means new dies. The three-fourth dimension would be much better because those sections are already in use. And of course the washer manufacturers have steel on hand for those sections, but they have no steel on hand for a section contemplating two-thirds.

Mr. Seymour: In the typewritten recommendations nothing is said about parallel face lock washer, and as there seems to be some confusion between the terms "plane" and "parallel" as used by the different manufacturers, I would recommend that the following paragraph be inserted: "That washers shall be of perfectly parallel faces and that bulging or mal-formed ends shall be avoided." The motion was seconded. Carried.

Concerning the Report of the Carbureter Division

Mr. Vincent: Mr. Sweet suggests that we stop off at 2 inches and not try to standardize the (carbureter) flanges above two inches because those don't interest very many of us. If we get into 2½ and 3-inch size, we have got to go into the four bolt construction, and there seems to be a good deal of difference of opinion in regard to the proper arrangement in the four bolt construction.

There was considerable discussion about the exact form of gasoline and water unions and the form of the throttle connection. The Standards Committee didn't exactly like the report of the committee on this arm, as they thought it was not quite definite enough, and it seems to be a general feeling that it would be impossible to standardize the throttle arm further than possibly the size of hole and the thickness of the boss at the end of this arm, which should be ¼ inch for size of hole and 9/32 thickness of boss, to correspond with A. L. A. M.

In going over a great many different carbureters some variation in size of pin was found. One manufacturer might have it ¼ inch. Another manufacturer will go 1/32 over that, or 1/32 under it. So that these flanges have been laid out sufficiently large to give reasonable gasket width, even on the largest opening, and of course the gasket will be a little larger on the smaller opening, but we have tried to strike a happy medium and not change anybody's flange very much. You will note that all the well-known carbureters follow this design closely. There were just enough differences to keep it from being interchangeable. The first thing to take up and see what we can settle on would be the matter of flanges. Is it the consensus of opinion that it would be well to stop off at two inches for the present and not try to standardize anything over two inches?

Mr. Sweet: The report is not quite complete, and we thought that we had better cover the sizes up to two inches, and then we can add information—after we can agree better on that point—above two inches. Mr. Vincent has said that the attempt has been made to change the standard flanges as little as possible. Having something to refer to until we get better information, we can refer to the Society's standards for two inches, and we will all know what we are talking about.

Mr. Briggs: It would be impossible for us to change at present to the sizes given there. We have written to several carbureter manufacturers, and they have all agreed to make them one standard. There are three or four manufacturers that have agreed to make it to standards such as we now use, and we wouldn't like to have this thing settled without a little further getting together of the manufacturers. We are all trying to standardize with the standards we now have. They make a very serious difference as regards the water jackets, and it would mean absolutely upsetting the entire factory, and also would make a considerable change with a number of customers who have their manifolds drilled to our standards.

President: Various attempts have been made to get the carbureter manufacturers interested in this problem. The response has not been very quick. Consequently the committee places before you something that seems right. The other aspect of the situation is this: that there will be no immediate revolution, but the changes made will be made in connection with new designs. That is, assuming that an engine is to be designed next month,—instead of taking something that exists or something new, as might be done, the engineer or draftsman will go to this little data book and take what would be known as a standard flange. Now, if that standard is a bad one, that is what we want to bring out at this time.

Mr. Briggs: Suppose the manufacturers of carbureters should all agree on a standard—would that suit the Society—if we would get together?

President: I would say if the gaskets were wide enough and of a suitable shape and pretty much like these, why, something might happen.

Mr. Briggs: The difference would be very slight,—it would be a thirty-second here or there; nothing radical. Nothing different in the design or in the general appearance of the flanges here.

President: The situation is this: If the carbureter people had come forward, they would have had a hand in it and the whole matter would have been adjusted at this time. Now, to get action, the committee places something before you. If it is bad, say so. If it is good, adopt it.

Mr. Briggs: The only statement that I had to make was that the difference is very slight, and I thought we ought to see the manufacturers before deciding on this and see whether they would rather use the standard that now exists among two or three of the manufacturers or wanted to have them changed over to the proposed standard. It wouldn't take much time.

President: We are confronted by exactly the same thing that happened in the tire matter. All have got to yield something. The differences of various carbureters have been in the hands of the committee for some time and were in the hands of the committee when these sizes shown on our blue print were adopted. Now, Mr. Behn tried to justify the differences and make the difficulties just as small as they could be; that is, not to punish any one company by radical changes, and that is what the blue print is supposed to represent.

Mr. Sweet: Each manufacturer wants to influence the standard towards that he is himself using. And if we leave it to the manufacturer we won't have uniformity. And the best results will be obtained in general if you follow out some uniform system that the committee has suggested.

President: In other words, you feel that these flanges are a fair solution of the problem?

Mr. Sweet: Yes. We find the carbureters wanting to cover an extra 1/16, and they rub the flange surface, and the flange is so light that the work will have to be very nicely done or the carbureter will leak. I believe that these standards are reasonable.

Mr. Vincent: I would like to explain that it is the committee's idea that these flanges should be put into the note book as soon as possible, and that it wouldn't affect current models, but when we design a new engine, we could then use the standards. For instance, if we were designing a new engine and wanted to use a freak flange, the chances are we could get the manufacturers to make the flanges for us; and why not lay out carbureter flanges along the same lines, instead of making new designs? If we could get carbureters with the same size flange, that is going to simplify the proposition, and as you run out of current models, the carbureter manufacturer will drift into the standard flange. So it don't look to me like it will place a hardship upon him.

Mr. Pope: I would like to make a motion that the report of the Carbureter Division of the Standards Committee be adopted as far as the sizes of flanges is concerned up to two inches. Seconded. Carried.

Mr. Vincent: The next point is the matter of gasoline and water connections.

President: That was very carefully discussed by the Standards Committee and the point brought out as to the length of the connection. Its advantages,—removing vibration, supporting the pipe, making repair easy. A motion would be in order to accept the report as far as these connections are concerned.

Mr. Birdsall: I move the report be accepted, in that particular. Seconded.

President: It is moved and seconded that the report be accepted as far as the gasoline and water connections.

Mr Aull: As I remember, at the Standards Committee meeting the other day, the suggestion was made that you standardize the pipe connections. It is not indicated here. It should indicate the size of pipe that can be used on a certain number carbureter. There ought to be something done.

Mr. Vincent: Personally, I would like to have seen the connections standardized for each size carbureter, but as there seems to be so much variance in the size of pipe used, it seems almost impossible to standardize the pipe connections at the present time. I must admit that I don't know just how to go at that,—to get down to a standard on it. Of course, it would be possible to tap out all carbureters large enough to take the largest pipe,—but whether or not that would be a good idea, I can't say.

Mr. Sweet: The fear along that line is on account of the various systems. One using the pressure system can get along with one kind of pipe, and one using another system wants a different size pipe. It would seem unwise to establish that for all. This report, as was suggested, is quite incomplete. Whether we have accomplished enough to adopt certain portions of it is for you to decide. It was our opinion to submit the report as far as it had gone and add to it later.

PRESIDENT: Is there any danger in using this standard connection up to two inches?

MR. SWEET: I think not. I think it is very good up to the two-inch sizes. The reason we wanted to omit these larger sizes was we didn't feel just sure about them. We have been impressed with the fact that this supporting portion must be of quite definite size because if that is carelessly done and made 1/32 over size, it is entirely worthless. It has got to support the pipe very closely, and the difference there is to be recommended later. If you see fit to pass upon this, it is incomplete, and we feel that we could improve it very much before another meeting.

PRESIDENT: If the manufacturer takes hold of what we now have, we will be no worse off than we now are, because I will assume that he will make a reasonable fit. He tries to do it now, and he will try to do it with this standard before him, and that is a matter that can be refined. It is in the nature of a refinement rather than a radical change.

MR. VINCENT: The only other point is on the matter of throttle arm, and it is the opinion of your committee that it is almost impossible to standardize this throttle arm further than possibly indicating the size of the hole and the thickness of the boss. We believe that, after considering the matter in the light of the Standards Committee's suggestions that the hole should be ¼ inch, instead of 1/64 larger than the diameter of the pin or bolt, and that the thickness of the boss, 9/32, is O. K. That will conform to what has been the standard A. L. A. M. rod. I believe that all members of our committee would be glad to see the cut taken out and the dimensions given as a suggested standard for the throttle end; that is, quarter-inch hole and 9/32 thickness of boss.

MR. POPE: I make a motion that the eye of the lever be adopted as shown in the cut and stated by Mr. Vincent. Seconded. Carried.

MR. AULL: The motion was carried before the Standards Committee the other day to make the minimum length of lever two inches.

Views of a British Expert

The following extracts from the speech of Arthur Ludlow Clayden, editor of the *Automobile Engineer*, of England, proved to be one of the most interesting of those made at the banquet of the Society of Automobile Engineers at Dayton, Saturday, June 17. Among other things he said:

"One of the most interesting things I notice here is the difference between the automobiles of England and those of this country. One hears a great deal about the difference of the conditions in this country and in the United Kingdom. After all, it is a matter of road surface and variation of climate and temperature. It only means that your task is more difficult than the task we have at home. It really means that you have to guard against certain things we don't have to guard against.

"With respect to the engine, I see no reason why the small-bore long-stroke engine, which has proved in England undoubtedly superior to the older type, should not be found useful to you. I believe it is possible to make a long-stroke engine that is lighter. It runs at higher speed and you get less trouble in your transmission. And I should think that where roads are bad that would be even more advantageous than where roads are good.

"There are of course a great many engines in England in which the stroke-bore ratio is 1.5. There are a number of engines with stroke-bore ratios of 2. It is a little bit difficult to express a definite opinion. I am inclined to think that 2. is carrying it a little too far. But I think 1.75 will become quite common.

"Of course, the speed of these small engines is very high, too. I recall one that had a bore of 80 and a stroke of 120, and the number of revolutions was 3850 per minute. It is a little bit hard to believe. But in that case the valves were special and their diameter was considerably more than half the diameter of the cylinder.

"The great difficulty with these engines has been lubrication. Splash lubrication is entirely out of the question with an engine running at such high speed. The controlled splash with dippers on the back ends has proved useful for the comparative high-speed engine. But it is certain that the engine where the oil is flowed with force pressure is more durable. Of course, the Lanchester engines have always been so. They are supplied with oil where it reaches the engine at 30 pounds per square inch. The same applies to a number of others, and these engines last very much better than engines with splash lubrication.

"The great trouble with these engines has been the balance. That may be overcome in two ways. One is by making the reciprocal parts much lighter and also paying attention to rotation balance of flywheel and crank shaft. The other is by adding a number of cylinders and using small six-cylinders instead of large four-cylinders. That has signs of getting to be popular. That has difficulties owing to shaft whipping. That rotation balancing machine is doubtless going to help us put it right, and bearings between each crank throw are also essential. We have found that that balancing trouble is one of the most powerful influences against ball-bearing crank shafts. The ball-bearing crank shaft gives too little rigidity. It doesn't give you a rigid support, and the crank is going to roll around on the balls to any extent it likes; and there is very good reason to believe that it does so at high speed.

"The only other thing about engines is with reference to two-cycle engines. The two-cycle engine is coming to the front very much. I think it is an open question whether the engine in the future is going to be a two-cycle valveless engine or four-cycle engine. I believe in the possibility of the rotary valve over every other kind of engine. I think the rotary valve is the most mechanical idea. I won't say that I have seen any rotary valve engine which seemed to be obviously the right thing. I think we are going to get an ultimate type which will be a very good engine. Which of them it is of course time alone will show.

"The two-cycle engine has been made in very many forms. I believe that more two-cycle engines have been built in this country for body work than in all the rest of the world. The pump-filled two-cycle has also received a good deal of attention. And the Lamper engine was one of the few which was really feasible. It gives a very good gasoline economy. The N. E. C. engine which is oiled by the splash method is another engine that has appeared feasible. Then the Illinois engine,—now there are two cylinders connected with a common composition chamber, so that the fresh gases have got to pass through the whole system before they get to the outside. That is also very successful.

"The next point which we have been spending much time over is the quieting of transmission and axles. The manufacture of a perfectly quiet gear is always likely to be a matter of very great expense. If you are going to run spiral gears, they will have to be as accurate as a ball bearing or even more accurate. They will have to be ground perfectly and as far as I am aware there is no method for grinding small spiral gears which is anything like practical on account of the cost. Very much the same thing applies to bevel gears. Therefore I think the worm gear will come in entirely for the back axle, and I am not very sure out what the chain will not come into ordinary use for pleasure car work, as well as for truck work. There is one advantage of the chain box for truck work—we find in England that omnibus drivers and truck drivers are very careless men. They are likely to knock the transmission, but the worst thing you can do to a chain transmission is to break the chain. The cost of renewing the chain entirely—not considering the cost of a few links—is very small; and it is absolutely nothing as compared with the cost of putting in a new spiral gear which has been stripped. To insert a new spiral gear means taking the whole box to pieces. I know the London General Omnibus Company claim that they saved six thousand dollars a year on work alone.

"We have been discussing a good deal at home as to whether we are not building our frames too rigidly. You have only got to watch a car going over a rough road to see that a frame cannot remain rigid; and yet the majority of frames are made to be rigid. That produces body troubles, which I notice you are getting over here by the very extensive use of metal. I was very much interested in some of the bodies I have seen as being enormously strong. But I should think that they must be bad in places, after the bumping that they get on some of your country roads. Still more does this apply to trucks. There again I don't believe that anywhere in the world people are making proper bodies. I think the structures are too rigid. And I think the future will show us some frames or body designs with a certain amount of spring to allow the whole body to roll about on the axle freely.

"Another point on which I should like some information, and I am going to endeavor to get it before I go back, is as to why brakes in this country are almost invariably on the hubs of the rear wheels. The external brake has disadvantages; the big disadvantage is shown when it plugs up with mud, and I am sure that is the trouble that is found here. Of course, the internal brake can plug up, too, and if you run cars down to the axle, I should think they would get just as bad treatment as any external brake.

"What surprised me was the absence of transmission brake. I have always found that I could use a transmission brake under certain conditions of road surface when it wasn't safe to apply the brake to the hub. I believe the brake going through the gear has an influence upon the non-skidding properties. I know that is so upon greasy macadam. I should think that it would be so here. Of course I realize that a propeller shaft brake throws a great deal of stress upon the transmission, which it doesn't receive with the hub brake.

"The front wheel brakes I have tried myself, and I have talked to a great many other people who have tried them. Some of our manufacturers are building them as standards and some if requested. The front wheel brake has the advantage of pulling you straight. It has a great disadvantage if you apply it hard enough to lose all control over the steering. I was trying a system of brake which acted on all four wheels at once. I have tried it under extremely severe conditions of road surface, and I found it was practically impossible to create a skid with it. I also tried using the brake on one front wheel and one rear wheel, on opposite sides. That kept it from skidding, while the power was slightly less than when on all four. We are bound to see some developments of that nature.

"Another thing which interests me very much over here is the system upon which most of your works are conducted. That is, a system where you have a chief engineer with a staff acting as an advisory committee of construction.

"I believe that some of the best engineers we have got in England began their work as repairmen and gained their experience through others' failures. I know that some of the most successful designers began that way; men who were actually at the bench in a country repair shop, and there had opportunities of noticing the things that broke in cars of every variety. I believe, therefore, that every designer ought to have a stay in a repair shop. I think that a man who has been designing for some years would find that it would help him to go out and work in a garage for six months.

"I have heard a lot about the difference between the wood that is obtainable in the different parts of the world. There is no doubt but that the hickory wood that you get here will build a better wheel than any wood we have in England; but it won't build a wheel that is anywhere near as strong as a wire wheel. It won't build a wheel that is as durable as a wire wheel. It has been claimed that wire wheels are easier on tires. I have no evidence on that. I don't think it is likely to be a very big difference.

"The tire wear comparisons are extremely difficult to make because it is hard to get the same conditions twice. Even if you put one wheel on one side of the car and one on the other,—even then one tire is on one side of the road and one on the other, and it is always different, when the traffic is going in one direction. But I do believe that the wire wheel or the steel wheel is going to displace wood entirely in England.

"The only slide motor which I had some personal experience with is the Knight. I believe the Knight engine's method of getting free of the trouble of noise and of rapid opening is a very good way. There is a wonderful number of them running in England and running extremely well. The great advantage is once it is right it stays right until it is altogether wrong. There is no valve-grinding. Another thing is that it runs much better when it has got a fair layer of carbon deposited. I think it is a cool engine; when you have got a bit of a layer of carbon on the inside that retains the heat and gives you better working conditions. I think it is likely to be very many years before any one type of engine comes out on top,—even indeed if it ever does. One finds modifications of one kind or another. There must be a great deal of personal choice on the part of the designer. I don't think it can ever be otherwise."

PROPER PLACE TO STOP—When stopping for any cause the automobilist should bring the car over to one side of the road so that it will be out of the way of other traffic. In doing this a position should be taken up so that when the car is started again there will be no difficulty in getting under way. In bringing the car to the roadside the driver not only allows others the use of the road but protects himself from being run into or hindered while making repairs, etc. On the other hand, drivers who are otherwise considerate sometimes remain in or near the center of the road, if the stop is an involuntary one, and commence repairs, hindering other cars from passing and running the risk of being hit.

Convenient Position for Tools

Editor THE AUTOMOBILE:

[2,723]—I am desirous of having a body built according to my own design and would like to keep the running boards as clean as possible. I have made provision to carry the spare tire in a drawer under the rear seats, which eats up a good deal of space, the cushions being made deep, as suggested by you recently. Could you give me an idea of how to carry some tools that are likely to be wanted from time to time and do away with the unsightly tool-box that is found on the step of nearly every car? My experience of these things is that they are not waterproof, besides being unsightly, and the tools become covered with rust if left in the garage for any length of time without being used. JOHN.

New York City.

The method shown in Fig. 1 should overcome your difficulty, as by this means the tools are kept dry and out of the way, but instantly accessible when wanted. There is another advantage, viz.: out of sight is out of mind, and there is less likelihood of some one "borrowing" anything without permission.

Authentic Information as to Indianapolis Race Is Hard to Get

Editor THE AUTOMOBILE:

[2,724]—In the issue of THE AUTOMOBILE, June 1, in the list of prize winners in the Indianapolis race, you gave Dawson (Marmon) fifth place, while the detailed account of the race you gave the fifth place to De Palma (Simplex). Will you kindly enlighten me in the matter through your columns?

SHEPARD WILLIAMS.

Newton Highlands, Mass.

THE AUTOMOBILE published in the issue mentioned all the information of an authentic character that could be had in relation to this matter.

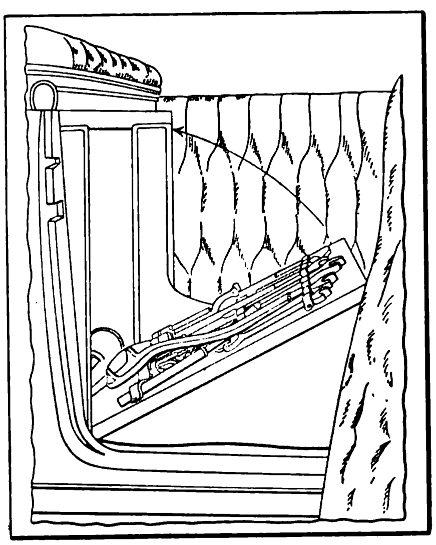

Fig. 1—Showing how the tools can be carried behind the front seats

What Some Subscribers Want to Know

Open the Exhaust Valve a Little Earlier

Editor THE AUTOMOBILE:

[2,725]—I have a four-cylinder motor with the following valve timing: Exhaust valve opens 45 degrees before lower center; exhaust valve closes 15 degrees after top center; inlet valve opens 20 degrees after top center; inlet valve closes 20 degrees after lower center. Will you be good enough to inform me if you could recommend any valve timing that would decrease the tendency for the motor to heat and at the same time not materially affect the power? E. EVANS.

St. Louis, Mo.

Quite a number of motors are so timed that the exhaust valve opens as much as 51 degrees early. You might emulate this good example. It is more than likely that your heating trouble is due either to an accumulation of carbon within the motor cylinders, or a scale formation on the exterior domes thereof; and it is also possible that the ignition system is too poor to properly ignite the mixture, in which event the flame travel will be retarded and overheating will be the normal expectation. Another way to lower the heating effect is to adjust the carbureter so that it will not deliver too much gasoline. This adjustment should be made when the motor is running slow, and the air adjustment should be accomplished when the motor is running fast.

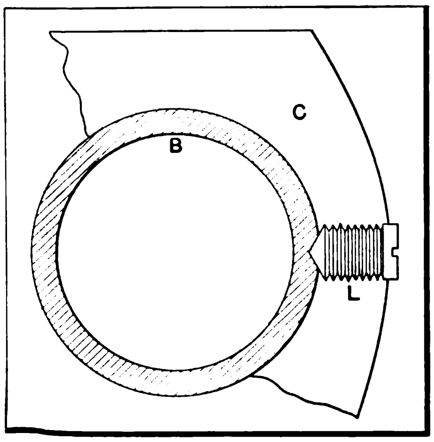

Fig. 2—Method of holding the camshaft bushings secure and preventing them from turning

Linseed Oil Will Prevent the Creaking Trouble

Editor THE AUTOMOBILE:

[2,726]—If the spokes of an artillery wheel creak when the car is started or the brakes applied, and tightening the hub bolts proves ineffectual, what should be done under the circumstances? It seems to be due to the spokes drying out and the application of linseed oil has been suggested. Only the rear wheels, which are subjected to the alternate driving and braking stresses, are thus affected, but the braking strains are unusually severe, as the brakedrums are not bolted to the spokes.

MURRY FAHNESTOCK.

Allegheny, Pa.

Take the flange off the wheel and apply linseed oil with a brush, taking enough time to make sure that the oil will soak in, then put the hub flange back and fetch up tight on the holding bolts.

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their automobile troubles, stating them briefly, on one side of the paper only, giving as clear a diagnosis as possible in each case, and a sketch, even though it may be rough, for the purpose of aiding the Editor to understand the nature of the difficulty. Each letter will be answered in these columns in the order of its receipt. The name and address of the subscriber must be given, as evidence of good faith.

How to Stop Camshaft Bushings from Turning

Editor THE AUTOMOBILE:

[2,727]—Would you kindly tell me, through your Letters column, how I can prevent the bushing of the camshaft of my motor from turning with the shaft. The bushing is made of phosphor bronze and the crankcase of aluminum.

Philadelphia. F. W. MARTIN.

The method shown in Fig. 2 will stop the bush from revolving; but in case the bush has increased the size of the hole it might be as well to have a new bush turned up. The crankcase C in which the bush B is housed should be drilled and tapped to take a small set screw L.

Address the Maker, Who Will Apply the Remedy

Editor THE AUTOMOBILE:

[2,728]—Being a constant and interested reader of THE AUTOMOBILE I take the liberty of asking you for a remedy for my Packard car. I have driven a Packard "30" for 15,000 miles and then had it overhauled in the agent's repair shop. Since then I have had trouble with the water; in driving my car over a mountain road on second speed it will boil. It never did this before it was overhauled. The circulation seems to be good and the radiator is clean.

What Other Subscribers Have to Say

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their personal experiences for publication in these columns for the worthy purpose of aiding brother automobilists who may be in need of just the information that this process will afford. Communications should be brief, on one side of the paper only, and clearly put, including a rough sketch when it is possible to do so, and the name and address of the writer should be given as evidence of good faith.

It has plenty of power and runs very free. A remedy for this will be very much appreciated. DRIVER.

San Francisco, Cal.

Interest Centers in the Motor Scavenging Problem

Editor THE AUTOMOBILE:

[2,729]—As a constant reader of THE AUTOMOBILE I have become very much interested in a means you mention for a more complete scavenging of a motor in your issue of May 18 on page 1142. I take the liberty of asking you where I can receive more information or reports of tests on the subject or if you know of some motors on which this scheme is used.

A. G. ROSENTRETER.

Boonton, N. J.

We have no information relating to the use of a device as referred to on page 1142 of THE AUTOMOBILE of May 18, as shown in Fig. 43. Isolated uses of a device more or less of this character would seem to indicate that it is an efficacious device.

How to Find Critical Speed

Editor THE AUTOMOBILE:

[2,730]—I was interested in a reply to a letter that appeared recently in your paper with reference to cars overturning, and on reading some literature on the subject I came across the words "critical speed." Could you tell me how to determine the critical speed? J. W. T.

Shenandoah, Pa.

First find the center of gravity of the car fully loaded and let this be represented by S as seen in Fig. 3. AB represents the wheel track and the line MS perpendicular to AB. Then, as the wheel A is just about to lift off the ground there can be no pressure there, and hence if the moments are taken of all the forces about B the sum of the moments must be zero. That is, $F \times SM - W \times MB = 0$.

If W = the weight of the vehicle,

V = the velocity in feet per second,

R = the minimum radius of curve through which the steering wheels will turn the vehicle, in feet,

$g = 32.2$,

F = the centrifugal force acting at S due to the turning action of the vehicle,

Then

$$F = \frac{WV^2}{gR}.$$

$$\therefore \frac{WV^2}{gR} \times SM = MB$$

Canceling the common factor W, the equation becomes

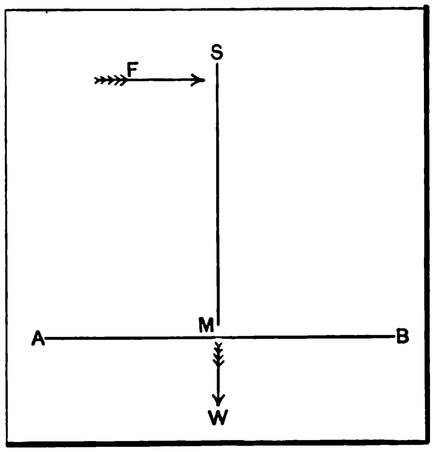

Fig. 3—Diagram used in determining critical speed

$$\frac{V^2}{gR} \times SM = MB.$$

$$\therefore V^2 = gR \times \frac{MB}{SM}$$

$$V = gR \times \frac{MB}{SM}$$

Simple Ignition Wire Attachment

Editor THE AUTOMOBILE:

[2,731]—I have been troubled with the ignition wires of my new car. They are all loose, and apart from making the motor look untidy they rest against the hot cylinders. I suppose the heat will have a bad effect on the rubber. Could you suggest a simple method of holding them together?

TROUBLE.

Mullica Hill, N. J.

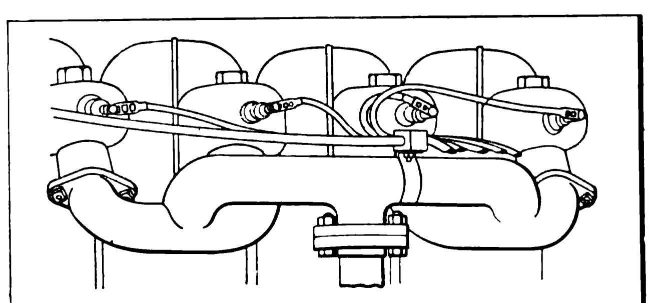

Fig. 4—How the loose ignition wires can be kept from rubbing against the cylinders

Take a piece of fiber and drill four holes in it for the wires to pass through, so that they will be a snug fit in the manner indicated in Fig. 4; then, with a bolt and nut and a piece of sheet metal, a clamp can be made to hold the bracket on to the intake manifold.

The Left Hand Should Be Used in Cranking a Motor

Editor THE AUTOMOBILE:

[2,732]—I saw in your paper some time ago an article on cranking a motor. I do not agree with you that the right hand should be used, as there is great danger of striking the wrist should the motor backfire. There is a tendency to throw the hand into the path of the crank. The proper way is to use the left hand, then a backfire will do no harm, as the hand is thrown away from the path of the crank. I have tried both ways and only yesterday I had a backfire and carelessly used my right hand and got hurt some. I consider it very dangerous to crank with the right hand. W. W. TREVOR.

Lockport, N. Y.

We do not call to mind having recommended right-hand cranking, nor would we consider doing so excepting in individual cases when the left hand is out of training.

E-M-F Gear Ratio

Editor THE AUTOMOBILE:

[2,733]—Will you kindly inform me, through your columns, what the different gear ratios are on the E-M-F "30"?

Johnstown, Pa. W. G. M.

The ratios are as follows:

High gear—3¼ : 1.

Second gear—6¼ : 1.

Low gear—11 : 1.

Reverse—6¼ : 1.

Get the Maker to Support Suitable Equipment

Editor THE AUTOMOBILE:

[2,734]—We have a four-ton Knox truck which we would like to limit to 12 to 15 miles per hour. Can you give us the name of a manufacturer of a governor which we can attach to same?

E. P. LUTZE.

Buffalo, N. Y.

Meeting Recurring Troubles

Presenting a Series of the Most Probable Cases

A series of correlated short stories, accompanied by diagrams and characteristic illustrations, including the nature of the troubles that are most likely to happen to automobiles, discussing their causes and effects, all for the purpose of arriving at a remedy. It is the aim, for the most part, to show how these troubles may be permanently remedied, and as a secondary enterprise it is indicated how the automobilist can make a temporary repair, thereby enabling him to defer the making of a permanent repair until a convenient time arrives.

Splash Lubrication of the Kissel Kar—The Kissel Kar four and six-cylinder motors are lubricated by the splash system. The oil tank is located in the base casting of the motor and forms the lower half of this casting. The oil reservoir is filled through a large filler opening in the forward left-hand side of the crankcase, which is marked in large letters: OIL. The filler opening is opened by means of a hinged cover which can be lifted and swung back.

The oil is drawn from the engine base by means of a rotary gear pump, driven off the cam shaft. The pump forces the oil into the splash troughs located in the upper base casting, on a sort of tray above the reservoir. There is a splash trough below each cylinder.

After having filled each of the splash troughs the oil is allowed to flow into a drain pipe, which runs the entire length of the crankcase. This drain tube is punctured by a long slot at each trough through which the oil enters the tube and drains back to the rear of the engine and down into the reservoir. There is a lever on the forward left-hand crankcase supporting arm, which may be raised or lowered, thereby turning the tube which contains the slots and respectively raising or lowering the point at which the oil may flow into the tube. The level of the oil in the crankcase at any time may be determined by means of a level gauge glass on the side of the motor.

As has been seen, the crankcase is sub-divided into an upper and lower half. The upper half has a trough below each connecting rod throw, into which the connecting rods dip, churning the oil therein into a flying spray or vapor.

The excess oil drains off the cylinder walls and flows back into the troughs, and in like manner drains off all the other bearings back into the same. After overflowing the oil will be drawn through the pump and be used over again. Before entering the pump the oil passes through a screen in the base of the motor.

This screen and the pump itself should be often removed and cleaned. The brass inspection plugs on the left-hand side of the crankcase should also be removed from time to time, to see that the oil openings in the supply pipe from the pump to the splash troughs are not obstructed in any way, as this would allow a greater supply of oil to get into one cylinder than another.

The timing gears are oiled by the connecting rod splash by means of an oil pipe which leads from the crankcase into the timing gear case. Other bearings all over the car are lubricated by means of oil holes or grease cups, as the case may be; while the transmission and differentials are packed in oil and grease.

Lubrication in Amplex Valveless Cars—The Amplex Model H. 30-50 horsepower car is lubricated by the force feed system. The crankcase is divided into three horizontal sections. The lowest section of the three is an oil well and this taken in conjunction with the oil in the force feed box carries the oil supply.

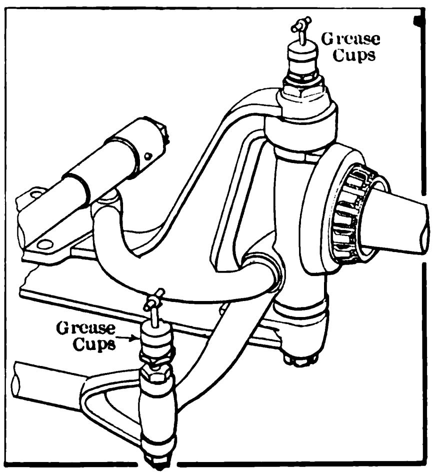

Fig. 1—Illustrating the manner of oiling steering knuckle on Amplex automobiles

The force feed oiler is of the Hancock type. It is driven by gears from the crankshaft. The oiler is located on the exhaust side of the motor and takes up about half the length of the engine. It is boxlike in form and rests on a broad flange which projects from both sides of the crankcase for the entire length of the motor. The reservoir is cast integral with the crankcase.

Near the front end of the mechanical oiler box the filler hole is located. A spring cover can be lifted up on a hinge when filling the oiler, exposing the opening which contains a gauze screen through which the oil is poured.

A pump sends the oil from the reservoir through a sight feed on the dash, back to the mechanical oiler, then through a separate lead to each cylinder and main bearing as well as to the timing gears. There is one lead to each of the four cylinders, to the five main bearings, and to the timing gears.

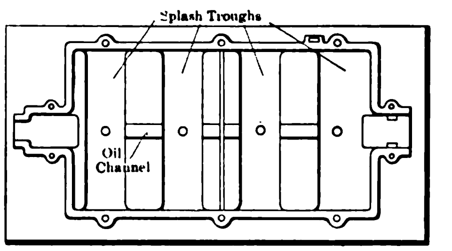

Fig. 2—Looking down into the oil reservoir as it is used on Kissel Kars

The flow through each of the leads may be made to be a certain proportion of the total flow, which is governed entirely by the speed of the engine, since the oiler is driven off the crankshaft. The relative speed of the whole oiler to the revolutions per minute of the engine is determined by the gears, but the amount of oil delivered depends on the stroke of the oil pump. This can be governed directly from the dash by means of a lever. This lever projects from the top of the oil box at about the center and is drilled at the top to allow a rod to be attached so that it may be operated from the dash.

Each oil lead has a sight feed on the top of the oiler box. A main sight feed located on the dash shows whether the whole system is working properly or not.

The oil drains into the bottom of the oil pan in the lowest part of the crankcase and will gather there in a quantity if too much oil is supplied to the main bearings and cylinders. In a case like this blue smoke will issue from the exhaust pipe and the lever on the dash may be used to diminish the supply of oil given to the motor.

There are drain pipes located in the bottom of the crankcase through which the oil may be allowed to flow out.

There are compression grease cups on the water pump bearings, steering knuckle bearings and all over the car at the revolving or oscillating bearings. The transmission and differentials run in oil while the universal joints are packed in grease.

Force-Feed Oiler Used on Stoddard-Daytons—The Stoddard-Dayton model 11-K four-cylinder car is lubricated by the force-feed system. The crankcase forms the oil supply tank and carries about two and one-half gallons.

A gear-driven oil pump which is actuated by the camshaft takes the oil from the base and pumps it into a manifold which serves as a distributor. The leads are supplied from this distributor and run directly to the crankshaft and camshaft bearings.

After lubricating the various bearings, the oil drains back into the bottom of the crankcase, which is covered with a baffle plate to prevent the oil from splashing into the cylinder in case the connecting rods should dip into it. The force-feed system is designed to completely and sufficiently lubricate the whole engine. On the rear right-hand crankcase supporting arm there is an oil level gauge glass. The oil in the reservoir should never be allowed to fall so low that it is not visible in the level glass.

When starting on a trip the oil level in the crankcase should be examined and if a sufficient height is not indicated on the level gauge, the reservoir should be filled. This is done by means of a filler pipe located between the two central cylinders.

The amount of oil supplied can be governed by means of a regulating nut on the side of the crankcase. To increase the supply of oil sent to the distributor the lock nut should be loosened and the regulating nut screwed down a turn or two, the lock nut is then tightened up again. To decrease the supply the process is naturally directly opposite to that of increasing it.

On the dashboard there is a pressure gauge which indicates the pressure on the pump. This

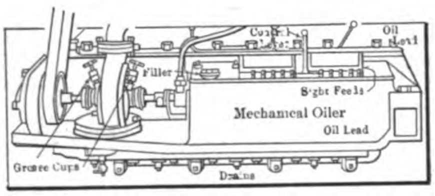

Fig. 3—The mechanical oiler of the Amplex and indication of oil distribution

pressure for ordinary country work should be about two pounds. For city use, however, the pressure need not be as high as this.

As the oil by this system is used over and over again it is evident that an adequate straining system must be employed, so a strainer is placed so that the oil passes through it before entering the pump and another which strains the oil before it returns to the reservoir.

Oiling Apparatus in Use for Colby Cars—The Colby "40" is lubricated by both the splash and force feed systems. The lower half of the crankcase is divided by means of a horizontal partition into two parts; the lower part forming the oil reservoir and supply tank for the motor. The horizontal partition or tray is shaped so as to have a depression forming a small well beneath each cylinder. These walls are the splash troughs.

The oil in the splash troughs is constantly added to by that which escapes from the force feed system through the crankshaft bearings. As the oil is supplied to the splash troughs faster than it is used, there will always be an overflow over the walls of these troughs. This overflow finds its way back into the oil reservoir by means of overflow holes.

The force feed system is entirely separate from the splash system just described except that the oil for the splash is replenished by the oil flowing off the bearings supplied by the force feed system. The latter is operated by a gear pump driven off the camshaft by worm gears. It is located within the crankcase, which has a recess in both of its halves to accommodate the pump, pump shaft and gear. The pump may be removed from the pump chamber through an opening in the bottom of the crankcase.

The pump and gearing are located at the rear end of the crankcase on the left-hand (exhaust) side of the motor. This pump delivers oil to the main bearings under a pressure of about four pounds. After lubricating these bearings the oil is carried by centrifugal force through ducts in the crankshaft, into the connecting rod bearings. Then the oil will be thrown off the cranks and connecting rods into the cylinder or work its way up to the wrist pin.

The excess oil drains back to the oil troughs, which are constantly kept overflowing; the overflow draining back to the pump recess, where it passes through a strainer. The capacity of the oil reservoir is two and one-half gallons.

The transmission is packed in non-fluid oil as are also the differentials and the universal joint between the clutch and transmission. The other bearings are equipped with grease cups.

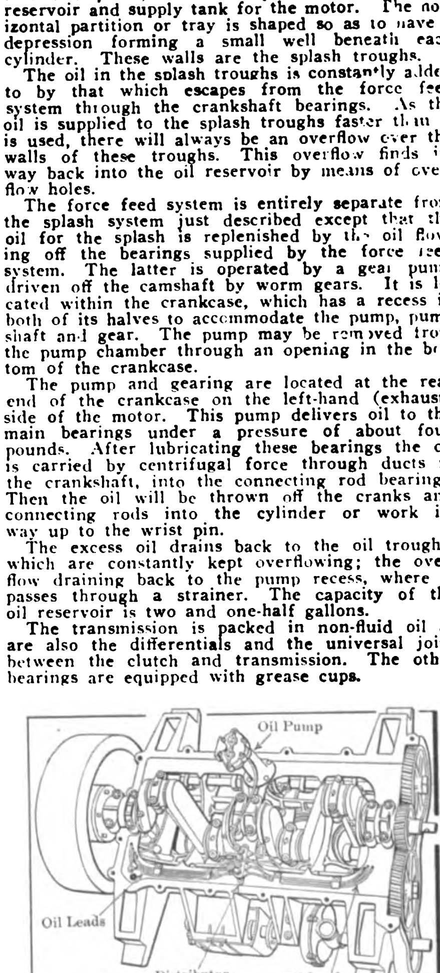

Fig. 4—Looking into the crankcase of the Stoddard-Dayton from below, showing oil leads

Lubrication of the Moon "30"—The Moon car is lubricated by the splash system. The oil supply is carried in the crankcase, which is so divided as to provide an oil reservoir in the bottom, as well as to carry a set of splash troughs. The splash troughs are carried on a horizontal partition which is cast directly in the base of the crankcase, being an integral part of the same.

The capacity of the reservoir or oil tank is about two gallons. It may be filled by either of two methods; that is through the breather tube in which there is a strainer or by means of the pump cover plate on the left-hand side of the motor.

The oil is drawn from the reservoir by means of a plunger pump, which is driven off the camshaft by spiral gears, and takes the oil from the reservoir in the bottom of the crankcase and sends it through the sight feed on the dash. The oil then flows back into the crankcase and supplies the splash chambers with oil.

The troughs are of such a depth that an adequate amount of oil will be held in them to

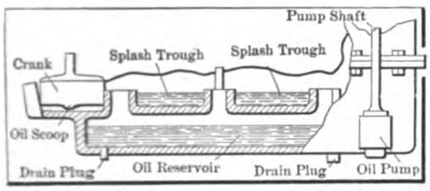

Fig. 5—Vertical section through Colby crankcase, showing location of troughs and pump

permit the bottom of the connecting rods to splash into the oil at any normal inclination of the car. When the oil overflows the trough wall it will drain back into the reservoir in the base. There are two large overflow stand pipes of elliptical shape. The purpose of making these overflow holes large is to allow the oil to drain from the splash troughs into the base as quickly as possible in case of an oversupply getting into the crankcase.

Between the two central splash troughs there is a solid wall of metal which is of the same height as the other trough walls. It does not form the enclosing wall of the overflow pipes as the other divisions between the trough do, but is pierced by two holes which form a communication between the two central troughs.

The oil is picked up by the copper scoops on the bottom of the connecting rods and thrown in the form of a fine spray up into the cylinders and the several bearings.

The train of gears which drives the camshaft on one side of the engine and the pump and magneto shaft on the other, are lubricated by the oil which they pick up from the trough which is in the bottom of the gearcase. This trough or oil well catches a supply of oil from the splash of the connecting rods. The gears dip into the oil and pick it up, thus carrying it to the top of the gearcase and into the bearings located in the case.

On the right-hand side of the oil reservoir there is a pet-cock at the correct level at which the oil must be kept. There is a large drain plug under the rear end of the base through which the oil may be drained completely out of the crankcase whenever the same is being cleaned.

The transmission and differentials are packed in grease, while the other bearings all over the car are taken care of by means of compression grease cups or oil holes, as the case may be.

Self-contained Fiat Oiling System—The Fiat car is lubricated by an entirely self-enclosed force-feed system. The lower half of the crankcase which carries the oil is formed so that the rear or flywheel end of the reservoir is the deepest part of the casting. There the suction pipe from the tank to the pump enters the casting.

There is a large drain plug in the base of the oil reservoir just below the point at which the suction pipe draws its supply from the oil in the tank.

The level of the oil in the crankcase is determined by removing the inspection cover provided for this purpose on the bottom half of the base chamber. The proper level to keep the oil is about one inch below the cover.

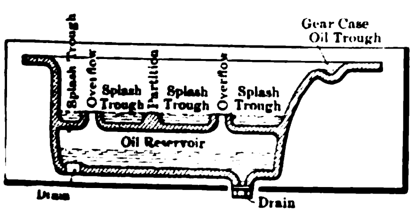

Fig. 6—The oil reservoir of the Moon car is formed by the base-chamber of the motor

A rotary gear oil pump, driven off the camshaft, lifts the oil from the reservoir through the suction pipe and forces it through a lead to the main bearings, then through the crank hollow shaft to the connecting rods, whence the oil is thrown up into the cylinders by centrifugal force, thus filling the crankcase with an oil vapor which is sufficient to lubricate the cylinders under ordinary circumstances. When running at higher speeds, however, the oil supply to the cylinder walls may be increased by pressing a button located on the dash. This button controls a valve which admits oil to a lead to the cylinders directly from the pump.

A pressure gauge shows the pressure on the oil pump. When the motor is running at normal speed the gauge should show a pressure of somewhere in the neighborhood of two or three pounds. When the pressure runs up beyond this point oil should be admitted to the cylinders.

When starting the motor after it has not been in use for a long time, it will often be found that the oil pump will not perform its functions properly. To aid the pump to draw properly in a case of this kind, a priming cock is placed on top of the oil pump, through which a little oil may be poured.

The gear box is kept filled to the level of the top of the gear shafts with medium grease. An examination of this bearing is advisable every two or three weeks.

Oiling System of Packard Cars—The Packard 1912 cars are lubricated by means of the splash system. The connecting rods dip into the oil, which is held at the proper level in a series of splash troughs in the crankcase of the motor. The splash of the rapidly revolving connecting rods into these pools of oil generates an oil mist which entirely fills the crankcase and lubricates all moving parts located within the crankcase.

The oil supply is carried in a tank which is entirely separate from the crankcase and is located on the left-hand side of the motor. The tank is made of copper and cylindrical in form. The copper construction of this tank and its location between the two middle cylinders, ensure a warm temperature for the oil while the motor is running.

The tank is filled through a filler opening in the

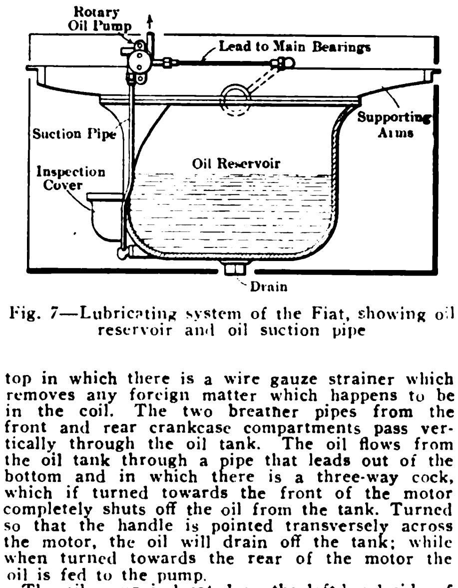

Fig. 7—Lubricating system of the Fiat, showing oil reservoir and oil suction pipe

top in which there is a wire gauze strainer which removes any foreign matter which happens to be in the coil. The two breather pipes from the front and rear crankcase compartments pass vertically through the oil tank. The oil flows from the oil tank through a pipe that leads out of the bottom and in which there is a three-way cock, which if turned towards the front of the motor completely shuts off the oil from the tank. Turned so that the handle is pointed transversely across the motor, the oil will drain off the tank; while when turned towards the rear of the motor the oil is fed to the pump.

The oil pump is located on the left-hand side of the crankcase at about the center of the engine in a longitudinal direction. It is on the outside of the crankcase directly below the oil tank. When the cock is turned to the rear of the engine and the motor is running, the pump will take the oil from the feed pipe and force it to the two sight feeds, located on the dash. The oil then drops through the sight feeds and flows through one lead to the rear crankcase compartment and through the other to the forward one. The pump is driven by means of a worm gear off the exhaust camshaft, and has two adjustable plungers, one for each of the two leads just described.

The oil carried in the copper tank is in reality the reserve supply of oil. That is, its purpose is to replenish the supply in the crankcase as it is burned up. Before starting the oil should always be put first into the crankcase so that the level therein is sufficient for the splash. To determine this level there are two pet cocks on the left-hand side of the bottom of the crankcase

The stroke of each pump plunger is independently adjustable. To increase the flow of oil in either lead, the adjusting screw and check nut should be turned downward for the plunger which governs the supply to that lead.

About every 1000 miles the old oil should be drained out by removing the drain plug in the bottom of each compartment in the crankcase. The crankcase should then be flushed out with kerosene, and, after this has been cleaned out, refilled with new oil.

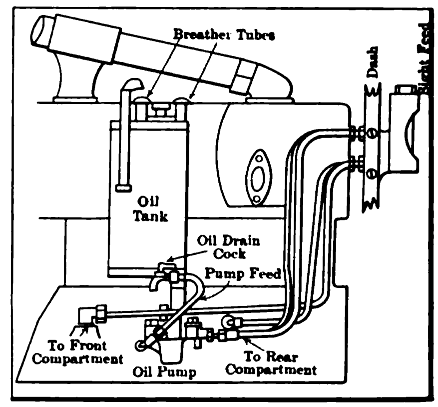

Fig. 8—Oil tank and connections for lubricating Packard cars of the latest type

Renault Oiling Scheme—The Renault cars are lubricated by the splash system. The oil is carried in the crankcase, which is filled through a filler opening located on the left-hand side of the motor just above the front axle of the car. The oil is taken by means of a pump driven by an eccentric and eccentric rod off the camshaft, and forced through a series of sight feeds located on the dash.

The sight feeds are marked by letters which stand for the French names of the parts which are taken care of by each of these oil leads. The leads are marked as follows: M.D., M.C., M.V. These three go to the motor itself, while the other two marked C.V. and E.D. (or E.A.) go to the gear box and rear axle, respectively.

The lead marked M.D. (moteur distribution) runs to the front main bearing; that marked M.C. (moteur central) to the central main bearing, and the one indicated by M.V. (moteur volant) to the rear of flywheel bearing. The amount of oil passing through each of these sight feeds may be adjusted to the requirements of each by turning the milled screws on top of the sight feed.

The connecting rods pick the oil from the series of troughs or compartments into which it is divided and throw it up into the cylinders. Besides lubricating the cylinders the oil is caught up by channels located in the upper part of the crankcase. These channels run longitudinally along the crankcase and are provided with small oil ducts above each bearing of the crankshaft. The oil will flow through these ducts by gravity to the bearings and from there into centrifugal oil rings on the shaft where it is naturally thrown by centrifugal force to the outer circumference of the ring.

Centrifugal force sends the oil into the crankpin, which has an opening so as to allow the oil to flow into the connecting rod bearing. The wrist pin will be lubricated also by the oil which works its way up from the splash, as well as that which is thrown there by centrifugal force.

To keep the oil in the splash troughs at constant level, the crankcase is divided into four transverse divisions. These may be put into communication with each other by means of a four-way cock which also drains the crankcase, separates the compartments and allows the oil to overflow to the correct level when there is too much oil in the splash troughs.

The change-speed box is packed in oil and grease which should be replaced occasionally. This can be done by removing the inspection cover. The flow through the sight feed into the lead to the change-speed box should show about fifteen drops per minute.

The remainder of the bearings all over the car are provided with grease cups or oilers.

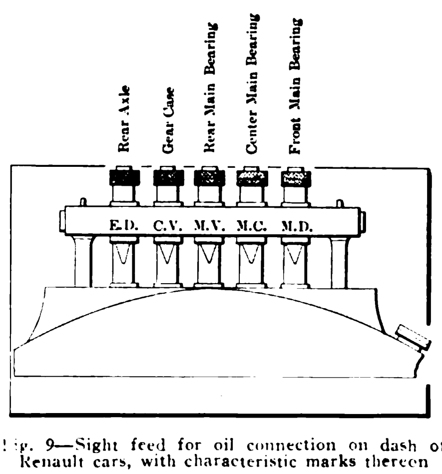

Fig. 9—Sight feed for oil connection on dash of Renault cars, with characteristic marks thereon

When Judgment Whispers Don't

A Series of Abbreviated Injunctions

DON'T discourage racing events and contests simply because they are difficult to control.

DON'T overlook the value of a "try-out" of an automobile under racing conditions—the weak spots float to the top.

DON'T try to build automobiles on a basis of pure theory—a real test welds theory to practice.

DON'T leave it to the purchaser to do the testing for the purpose of fixing the value of the product.

DON'T overlook the quality of the purchaser's money or the necessity of giving him an equivalent in the shape of a good automobile.

DON'T take it for granted that the automobile as made in your plant is good—a rigorous grind in a contest will develop that fact.

DON'T lay too much store upon circular track work—there is more to be learned during the length of a tour.

DON'T expect the control body to furnish honesty for you—it will have trouble enough keeping its own forces on the straight and narrow path.

DON'T be discouraged if a few false steps are to be found in tracing the past of contests—you have the whole future before you.

DON'T overlook the fact that however long the past may be it is but a moment as compared with the duration of the future.

DON'T mope if you are beset by a certain measure of failure—just make it a small percentage of the total and let the rest be success.

DON'T imprison a good idea in a poor setting—referring to an automobile, the good ideas will produce the right result if the car as a whole has been given a fair measure of attention.

DON'T practice mistakes after you find them out—the situation then becomes malicious.

DON'T incline the ear to drink in the story of the type of salesman who talks about everything but the subject in hand.

DON'T race with your money to put it in the coffers of the second-hand man before he races with the automobile to see if it is any good.

DON'T allow your incredulous smile to be supplanted by a serious look if the second-hand man gives you a more alluring version of the same story.

DON'T tap the boundless knowledge of the knave; there is no part of it that can be of any service to you.

DON'T permit yourself to be captivated by individuality; perhaps you need a good automobile instead.

DON'T pursue the business of buying an automobile according to a system that differs from the methods that you employ in the buying of real estate.

DON'T accept a demonstration if the car used has tires that are larger than the tire equipment of the automobile that you are taking an interest in.

DON'T overlook the importance of taking a demonstration in the particular automobile that you are to get.

DON'T harbor the fear that you will be giving the salesman too much trouble if you make him demonstrate the very automobile that you buy.

DON'T be satisfied with a wretched top on a good car—someone will take you for a ragman.

DON'T go in quest of a fool-proof automobile unless you belong to that fraternity.

DON'T expect that intelligent qualities will reside in a fool-proof car; intelligence never keeps such bad company.

DON'T cement your views to an incongruity, which is all that happens if you buy a car that is not in accord with your needs.

DON'T mistake a catalogue for the Bible, or forget that the maker's guarantee is in the back of the catalogue.

DON'T expect any more of redress from the maker than you will find reflected in the printed guarantee.

DON'T allow a salesman to make so little of you as to try to make you believe that his private guarantee will be underwritten by the maker of the car.

DON'T put your common sense up in camphor balls while you go to buy a car.

DON'T forget that you would have a fine automobile if you received the square root of the promises that are too often made.

DON'T boast of the speed that you can make with your car—somebody might get the impression that you are intemperate.

DON'T preach the doctrine of infallibility in connection with automobiles; the success of the automobile business depends upon the ultimate termination of the life of the cars.

DON'T assume that a good automobile should wear out before the purchaser gets a chance to pay for it.

Storage Battery Charging Equipment

THE study of the storage battery and its ailments is a subject which has not in the past received the attention it deserves at the hands of the average motor garage owner, and their charging is frequently placed in the hands of a youth who has no qualifications for undertaking this important duty, and yet on its proper discharge is frequently dependent the whole pleasure of the run. No garage owner who is alive to the welfare of his business can afford to ignore the advantages resulting from the installation of an up-to-date, efficient charging plant.

The storage battery, if properly looked after, is a piece of apparatus which will last for years, but no accessory on the car can be spoiled with such ease, a short circuit being sufficient to ruin the best of cells. The question then arises as to what method of charging best fits in with local conditions. In the towns it is an inexpensive matter to install a suitable plant, as a supply of electricity is almost always available, be it alternating or continuous.

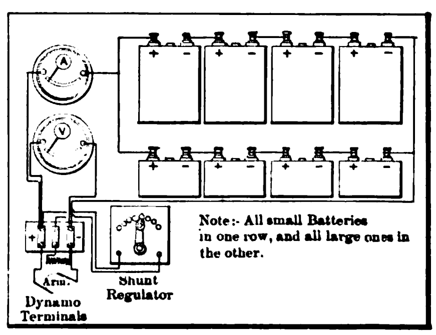

Fig. 1—Illustrating method of charging by a dynamo

CHARGING FROM A MAIN.—Should it not be known what the supply is, this can be easily ascertained from the supply company. If alternating current only is available, some form of transformer or rectifier is essential to convert it into continuous or uni-directional current, as alternating current theoretically surges backward and forward many hundreds of times a minute, first in a positive direction, then in a negative one, and if a storage battery is connected to this no charge is retained.

CHARGING FROM ALTERNATING CURRENT.—The transformer usually used consists of a motor wound for the alternating current circuit driving a continuous current dynamo; this set sometimes consists of a separate motor on a base coupled to a dynamo, but more usually the motor and dynamo are combined in one frame. The voltage on the secondary side of these transformers is always kept low in order that no waste is necessary in charging a small number of batteries, which will be explained later.

The rectifier is another method of converting alternating to uni-directional current for battery-charging purposes. The principle of the rectifier is to collect all positive and negative impulses and direct them to their respective terminals. It is usually made up of two parts—the incoming high voltage is led to a step-down static transformer, which reduces the voltage to a low figure, such as 6-8 volts, and this is then carried to an electro-magnetic rectifier, which synchronizes with the periodicity of the circuit on which it is fixed.

CHARGING FROM CONTINUOUS CURRENT MAINS.—If the supply is continuous current the choice of methods for charging is very much wider. The simplest, but by far the most extravagant, method of charging is by the use of lamps or resistances direct off the mains. This can be done by removing a lamp from its holder and inserting an adapter to which flexible leads are connected. A lamp or lamps should then be placed in circuit with the storage battery it is desired to charge, having first ascertained which is the positive and which the negative wire. This can be done by holding both wires in a cup of clean water about one-quarter of an inch apart with the current on, when bubbles will be seen to form on the negative wire. A good average rate of charge is 2 amperes for an ignition cell, and it will be necessary to connect six 16-cp. carbon lamps in series with the battery on a 200-volt circuit to carry this current, and half this number on a 100-volt circuit. This method of charging is not, however, to be recommended unless the light given by the lamps can be put to some useful purpose or charging is only very occasionally resorted to, as about 90 to 95 per cent. of the current consumed is absolutely wasted! Should, however, the number of batteries it is required to charge be large, say 30 to 40, then this method is to be recommended, as the above number of batteries will require practically the whole voltage of the mains if they are connected up in series.

The most efficient method, and the one usually adopted where it is required to charge a medium number of batteries off a continuous current supply, is by means of either a motor generator or a rotary converter.

The former consists of a motor wound for the voltage of the supply mains, coupled to a dynamo wound for a low voltage, such as 15 to 25. With these voltages the 4-volt batteries will be connected in three and five cells per row, and as many rows as the amperes will allow; the output of the dynamo can be varied by means of a shunt regulator, according to the number of batteries it is required to charge.

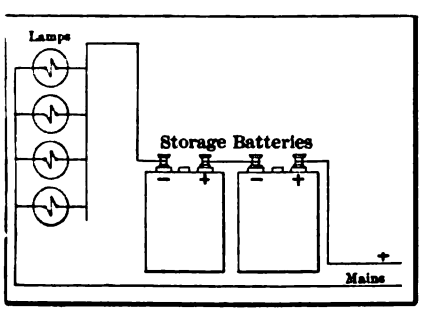

Fig. 2—Illustrating the method of charging a storage battery from a main, using lamp resistances for the purpose

The other method mentioned, viz., the rotary converter, consists of a single machine fitted with a commutator for collecting the current at each end, and a double set of conductors, viz., one set of fine wires connected to the mains or motor side, and a set of coarse wires connected to the secondary or dynamo side. This machine can be wound to give the same output as the motor generator mentioned above. Its advantages are: Slightly greater efficiency owing to the elimination of one pair of bearings, and the fact that this machine has only one pair of field coils instead of two; greater compactness; and less cost due to less material required in its manufacture. As a set-off to these advantages, any regulation required in output must be obtained through a series regulator, which is less efficient than a shunt regulator, and somewhat more expensive, but this latter machine has proved itself the more serviceable.

CHARGING BY DYNAMO.—Should no electricity mains be available, the problem before the man requiring to charge batteries is more serious. Some form of power is, however, necessary to drive this dynamo, be it gas or oil engine, gasoline or water motor. If the dynamo is required solely for charging purposes, the power required from the prime mover will be very small, 1-3 hp. being sufficient to charge as many as nine 4-volt storage batteries, but it is usually wise to install a larger plant than this and use the surplus for lighting purposes, as not only is electric light the very best and safest illuminant for the garage, but its cost compares favorably with even oil lamps. For instance, it is possible to light fifty 10-cp. metallic filament lamps for less than 3 cents per hour!

Having decided to install a dynamo, the question of the most suitable voltage arises. For all-around purposes 2 volts will be found the most satisfactory. With this voltage it will be necessary to connect the 4-volt batteries to be charged in series rows of five per row. Care should be taken in connecting up these rows to put, as far as possible, batteries of an equal size in the same row, as otherwise a small battery placed in a row with large ones will get too heavy a charge or else cause the large cells to be charged at a slow rate, which latter course, while not damaging them, will lengthen the time taken unnecessarily.

When the dynamo is lighting lamps at the same time as charging batteries, the voltage can, by means of a shunt regulator, be reduced according to the number of batteries it is required to charge. Thus, should there be only three 4-volt cells the dynamo must only give 15 volts, and so on. The regulation of the output of the dynamo obtained in this way is not at all extravagant, as the power required to drive it diminishes in the same ratio.

Another method of charging storage batteries is by means of a bichromate battery, but this method can only be recommended for use in the hands of an expert. This primary battery consists of a porous pot in which is a zinc rod amalgamated with mercury. This pot is placed in an outer jar in which is a solution of chromic acid and sulphuric acid. To charge one battery four primary batteries should be used. Each cell will give 1.1 volts.—*The Motor Trader,* May 24.

MERITS OF ZINC AND COPPER ALLOYS WITH ALUMINUM—For cheap aluminum castings a 33 per cent. zinc alloy with fusion point about 470 degrees centigrade is preferable, but for castings which must be particularly light and are subject to considerable deformation stresses an alloy with copper, though much more difficult to cast, meets the requirements better. There must first be made an alloy of 50 per cent. copper and 50 per cent. aluminum, which requires high heat and causes the formation of oxides and ashes. Commercially pure aluminum is added afterward, until the copper content is reduced to about 7 per cent., and the alloy has then a fusion point between 560 degrees and 622 degrees centigrade.

CANADIAN EXPORTS—Automobiles to the value of $43,650 were exported from Montreal, Canada, during the fiscal year of 1910, as compared $28,400 worth of exports of motor cars in 1909. St. Johns, N. B., sent $34,100 worth of automobiles to the United States in 1910, which was a decrease in comparison with the 1909 exports, when the value was $37,770.

It Stands to Reason—

(Remembering That the Exception Proves the Rule)

THAT the advance guard among automobile designers is making progress every minute.

THAT the purchasing public would be in poor business dogging the advance guard.

THAT every device must be tried out before it is entitled to a certificate.

THAT trying it on the "dog" is the regular thing.

THAT the "dog" ought to know when he gets enough.

THAT trouble will come soon enough—lubricate the parts and don't wait until they signal that they are in distress.

THAT the success of any art depends upon a certain amount of "try-out" work.

THAT a great many things are being tried out that will never be standardized.

THAT standardization comes when the public puts its stamp of approval upon the product.

THAT sanctioned practice is really the practice that pulls money out of a prospective's pocket.

THAT a little temporary success on the part of an upstart is in the nature of a remote contingency as compared with sanctioned practice.

THAT to get the opinion of an upstart he will convey the impression that he is the whole "cheese."

THAT the men pulling in the traces and making the wagon of progress go are not even groaning under the load.

THAT all the noise comes from the fellow who gambles on an idea.

THAT the automobile business in the main is an established institution remote from the gambler's pavilion.

THAT there are many little odds and ends attached to the automobile art that can well be dispensed with.

THAT the shepherd of the automobile flock is counting his sheep with a good deal of care these days and the goats are being separated out.

THAT there can be no retreat from the present status of the automobile business—advance is the order of the day.

THAT there is too much merit in good means of transportation to permit the project to falter by the wayside.

THAT most of the complaining that is heard is from the type of man who has insufficient funds to buy a good automobile and too little nerve to risk the other kind.

THAT the conflict of thought as it affects the designing problem is being reduced to its lowest terms.

THAT the designer who chums with a poor original idea might better copy his master.

THAT every designer has a master in precedent.

THAT taking due notice of sanctioned practice is no reason why an improvement should not be made in the due course of time.

THAT failure is due to the man who quits improving because he has an investment in perishable tools.

THAT the purchasing public does not care a rap about the investment considerations—they are willing to foot the increased bill if the product reflects the difference.

THAT the man who does not know how to act wisely can get his marching orders from the purchasing public.

THAT the jaded nerves of a worn-out motor are scarcely to be improved by a monkey wrench in the hands of a novice.

THAT too many automobiles are put awry by the careless use of convenient tools.

THAT an automobile should not be subjected to a surgical operation if it is going about its business and keeping still.

THAT good service is the shadow of good management.

THAT short life is the product of a speed lust.

THAT the user of a car holds no brief to tell the designer how to improve upon his stock.

THAT the designer of an automobile is in poor business plugging up his ear against the complaints of users.

THAT success in the designing office comes with vigilance and alertness.

THAT satisfaction on the road is a matter of care and caution.

THAT the designer of an automobile has no more right to perpetrate a poor product than a user has to abuse a good car.

THAT a happy situation is reflected when the designer and the user work together.

Short Stories of Current Interest

Unraveling the Puzzling Situations

Of the many things that automobilists take an interest in, some of them are on debatable ground, but it is generally true of such matters that they can be reasoned out even after algebraic formulæ fail to serve the intended purpose; it is the idea here to reason out some of these situations.

EVERY known element and compound, if it is changed from a liquid to a gas, must boil in the process. Water boils at 212 degrees Fahrenheit under a pressure of one atmosphere. Other liquids have various boiling points, and gasoline, for illustration, if it is to best serve the purpose for which it is used in automobiling, must be so compounded that it will boil at the surrounding temperature. It is a too common belief that nothing can be made to boil unless it is put into a pot or other form of receptacle and placed over a fire. This belief melts under the impetus of secondary thought, especially when it is remembered that some elements and compounds obtain only in the gaseous state under the normal conditions of temperature as we know it. The more volatile constituents of the hydro-carbon that is used to obtain gasoline are in gas form at the normal temperature, and for that matter it is scarcely believed that anything below hexane is sufficiently stable to constitute a good liquid to put in the gasoline tank. In the various fractions of hydrocarbons, so it would seem, there is a wide choice, beginning with the fractions that boil at the temperature of the surrounding air are slightly below and ending with the fractions that can only be made to boil when the air that is sent through the carbureter is preheated. The right time to stop off is when the fractions are so non-volatile that they cannot be induced to boil excepting in the greater heat of the combustion chamber.

WHEN carbon forms in the combustion chamber of the cylinder of a motor the operator of the car is made aware of the fact due to the cranky performance of the car under such conditions, and yet the explanation for this cranky performance presents a difficult situation to cope with. It is claimed by many designers of motors that the thermal efficiency will be on a higher plane if heat is prevented from getting out of the cylinder into the cooling water, and a coat of scale over the combustion chamber surfaces retards the flow of heat through the cylinder to the cooling water, so that in a sense the very deposit of carbon to which exception is taken is beneficial in its presence because it retards the flow of heat and conserves the useful measure of the same, thus increasing the power of the motor and decreasing the necessity for circulating cooling water. The effect of carbon in the combustion chamber is more marked as the compression of the motor is increased, and we must reach the conclusion that the placing of a layer of scale over the inner surface of the cylinder has the same effect to some extent as increasing compression. According to this method of reasoning it would be possible to increase the efficiency of the motor by putting a coat of scale over the flame-swept surfaces as well as by increasing the compression, since both methods seem to have the effect of increasing the rate of flame travel in the burning mixture. Following this thought a little longer makes it possible to reach the conclusion that there might be some advantage in running a motor under conditions of relatively low compression and courting the growth of the coat of carbon over the flame-swept surfaces in the cylinders. It has been found in practice that a motor acts precisely the same if the compression is 95 pounds (absolute) per square inch as when the compression is 10 or 15 pounds lower, and a coat of scale is permitted to grow over the flame-swept surfaces. It has been found also that with a compression of about 75 pounds per square inch (absolute) the effect of carbon deposit is materially reduced, and it might be that with a pressure of 60 pounds (absolute) per square inch the effect of the carbon growth would be so reduced that its presence might be disregarded.

WHILE the Society of Automobile Engineers were attending the Summer Meeting at Dayton, Ohio, a few days ago, there was quite a little discussion bearing upon the relation of a designing engineer to the man who purchases and uses a freight automobile. Some of the experts present advocated the employment of a second engineer, whose duty it would be to tell the designing engineer what the purchaser wants and whose second duty would fall in the direction of telling the purchaser how to conserve his investment and get a return on the same. There is some merit in the idea of using two kinds of engineers in this large commercial undertaking. It must be remembered that the designing engineer in the plants in which automobiles are made has a strong influence brought upon him for the worthy purpose of standardizing the output of the plant, and it would be nothing very unusual were the engineer to encourage the thought that one type of freight automobile should serve all the different kinds of users, and yet the point must not be overlooked that the wish is father to the thought. It is highly improbable that one type of automobile can be made to serve under all the commercial conditions to which freight automobiles offer advantages, and it is more than likely that an efficiency engineer who studies the wants of users of freight automobiles will be the best judge of the modifications of the main plan that must be indulged in ere the result will be satisfactory.

Calendar of Coming Events

Handy List of Future Competitive Fixtures

Race Meets, Runs, Hill-Climbs, Etc.

July 5-22..........Winnipeg, Man., Fourth Canadian Competition for Agricultural Motors.
July 7..............Taylor, Tex., Track Races, Taylor Auto Club.
July 8 or 15.......Philadelphia, Track Races, Belmont Park, Norristown Auto Club.
July 14.............Philadelphia, Commercial Reliability Run, Quaker City Motor Club.
July 15.............Guttenberg, N. J., Track Races.
July 15-17........St. Louis, Mo., Reliability Run, Missouri Automobile Assn.
July 17-19.........Cleveland, O., Three-Day Reliability Run of the Cleveland *News*.
July 17-22.........Milwaukee Reliability Run, Wisconsin State Automobile Association.
July 21-22.........Brighton Beach, N. Y., Twenty-four-Hour Race.
July 20-28.........Minneapolis Reliability Run, Minnesota State Automobile Association.
Aug. 1.............Chicago, Ill., Commercial Reliability Run, Chicago *Evening American*.
Aug. 3-5...........Galveston, Tex., Beach Races, Galveston Automobile Club.
Aug. 12............Philadelphia, Reliability Run, Quaker City Motor Club.
Aug. 12............Worcester, Mass., Hill Climb, Worcester Automobile Club.
Aug. 17............St. Louis, Mo., Reliability Run, Missouri Automobile Assn.
Aug. 25-26.........Elgin, Ill., Stock Chassis Road Race, Chicago Motor Club.
Sept. 1............Chicago, Ill., Commercial Reliability Run, Chicago Motor Club.
Sept. 1............Oklahoma, Reliability Run, *Daily Oklahoman*.
Sept. 2-4..........Brighton Beach, N. Y., Track Races.
Sept. 2-4..........Indianapolis Speedway, Track Races.
Sept. 4............Denver, Col., Track Races, Denver Motor Club.
Sept. 7-8..........Philadelphia, Track Races, Philadelphia Auto Trade Association.
Sept. 7-9..........Hamline, Minn., Track Races, Minnesota State Automobile Association.
Sept. 12-13........Grand Rapids, Mich., Track Races, Michigan State Auto Association.
Sept. 15...........Knoxville, Tenn., Track Races, Appalachian Exposition.
Sept. 16...........Syracuse, N. Y., Track Races, Automobile Club and Dealers.
Sept. ....Denver, Col., Track Races, Denver Motor Club.
Oct. 3-7...........Danbury, Conn., Track Races, Danbury Agricultural Society.
Oct. 7.............Philadelphia, Fairmount Park Road Race, Quaker City Motor Club.
Oct. 9-13..........Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 16-18.........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.
Oct. ....Atlanta, Ga., Track Races, Atlanta Automobile Assn.
Nov. 1.............Waco, Tex., Track Races, Waco Auto Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 7-10..........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9-11..........San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 10............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 28-30.........Savannah, Ga., Vanderbilt and Grand Prix Races, Savannah Automobile Club.
Nov. 30............Los Angeles, Cal., Track Races, Motordrome.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.

Foreign Fixtures

July 9.............Sarthe Circuit, France, Grand Prix of Automobile Club.
July 13-20.........Ostend, Belgium, Speed Trials.
July 21-24.........Boulogne-sur-Mer, Race Meet.
Aug. 6.............Mont Ventoux, France, Hill Climb.
Sept. 2-11.........Roubaix, France, Agricultural Motor Vehicle Show.
Sept. 9............Bologna, Italy, Grand Prix of Italy.
Sept. 10-20........Hungarian Small-Car Trials.
Sept. 16...........Russian Touring Car Competition, St. Petersburg to Sebastopol.
Sept. 17...........Semmering, Austria, Hill-Climb.
Sept. 17...........Start of the Annual Trials Under Auspices of *l'Auto*, France.
Oct. 1.............Gaillon, France, Hill-Climb.
Oct. 12-22.........Berlin, International Automobile Exhibition.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

WIDE interest is being taken in the types of motors that do not depend for their proper functioning upon poppet valves, and the supporters of the automobile industry are about to have an opportunity to inspect and try American-made Knight sleeve types of motors, as they are being manufactured by four companies of tried experience. In addition to this concrete effort, there is a strong undercurrent, with particular attention being paid to other forms of this broad idea, and the interested investigator will be struck by the diversity of effort and the impetus that is being given to original investigation in the face of the fact that designers who have had their nests well feathered are trying to teach the world to accept their marvelous handiwork as the last word.

* * *

TO the man who rests upon his hard-earned laurels, an early death and a heavy monument is all that the world affords; but we cannot bring ourselves to believe that glory in this form has any more compensations than will come to the progressive struggler who refuses to believe that finality hovers in the offing, and who goes on sweeping obstacles aside, holding tenaciously to the idea that there is something better higher up. As against the loud cry deprecating the annual model idea, the automobile industry is confronted by a more persistent and potent situation and the patrons of the industry are about to enjoy an opportunity to test the acumen of the builders, who seem to go on the principle that if there is nothing ventured there is nothing gained. It would be a foolhardy attempt on the part of a novice to try to market something new just because it is different; but there is a great difference between an innovation for sensation's sake and the supplying of a real demand.

* * *

JUST as refined society is conspicuous for its well-bred silence, so it may be said of a motor. If it does its work silently and well it will occupy a social throne motorwise that will attract the discriminating attention of the man who expresses a preference for the refined instead of encouraging the antics of the brawler. The time was when a silent motor was past believing, and the only hope that was entertained had for its foundation the thought that quite a little of the disconcerting sounds might be wrung out of the average motor. It is not believed that the purchaser of an automobile will concern himself overmuch relative to the scheme of design and the details of construction of motors in general, provided motors as used will do the work for which they are intended; on the further count, however, that the user thereof can take the evidence of his own ears and say to himself that the performance of the motor is silent.

* * *

UNEXPECTEDLY the builders of well-performing motors from the noise point of view were confronted by a strange situation. When they got the noise out of the valve mechanism they found that it had taken up its abode in the halftime gear system and in the drive for the magneto, water pump, and lighting dynamo. These relatively puny noises must have been in motors all of the time, but they sank into insignificance in comparison with the considerable clatter of the valves, only to be discovered when these great noises were removed. It was only half the battle to pay attention to the proper contriving of valve mechanism, and the other half of the struggle is being taken care of by the introduction of silent chain drives. Fortunately for the builders of all types of motors, the use of the silent chain is free to all, and we gather the impression that even the most inexpensive types of poppet-valve motors, as they will find a use in popular-priced cars, will vie in point of silence with their more pretentious brothers, due to the use of chain drives and the strangling of the grind that comes in the trail of ill-fitting gears.

* * *

FLEXIBILITY is the condition that makes it possible for a locomotive to start a train of 100 freight cars, and this desirable property is at no greater cost than the use of a spring in the coupling; and this flexibility, in addition to facilitating the work of starting, has a marked and favorable bearing upon the equipment. In the same way the presence of flexible members in the driving equipment of an automobile facilitates in the acceleration of the mass and saves the members in the machinery equipment from the ills of shock. There are two ways at the disposal of designers to overcome the ills of shock, one of which has to do with the use of dynamic steel at a price; but the second and perhaps the best way lies in the elimination of the shock. One of the distinct and desirable advantages attending the use of the silent chain lies in this very flexibility, the presence of which is the best guarantee that shock does not have to be entertained.

Fate of Dirt Tracks in Balance

M. C. A. to Take Action on Racing Next Month

Whether automobile racing on circular dirt tracks shall be continued or not on present lines will be the subject to be considered at the next meeting of the Manufacturers' Contest Association. The proposition will be taken up from all viewpoints, and the action that develops will likely be along the line of restricting racing of this kind. One point in particular will be considered, the methods of settling dust by other means than water in preparing for races. Sweeping prohibitory action would leave New York without racing representation for the present at least.

WHAT shall be the fate of dirt-track racing is a problem that has an interest for a circle considerably wider than that comprising motordom and it will be settled, according to announcement, by the Manufacturers' Contest Association at its coming meeting in August.

Automobile racing on the general run of county fair tracks that have not been specially prepared for such use has its dangers and certainly lends an element of peril to contests that is absent on the speedway or upon the specially prepared dirt track.

If general action should be taken by the association barring racing on all dirt tracks the situation in New York would be disconcerting. One thing seems to be certain and that is that the present situation will not be broadened. Therefore if action is taken it will likely be restrictive.

The association has issued the following bulletin covering the subject:

"One very important subject which will be given most careful consideration at the general meeting of the Manufacturers' Contest Association, to be held in August will be the question of racing upon circular dirt tracks. All over the country there are in existence one-mile circular dirt tracks built for horse-racing. The popularity of the automobile and of automobile competitions has prompted county and State fair organizations to feature racing among the head-liners of the "big days." In addition to this, racing events on circular dirt tracks are being advertised by individual promoters who have in mind the possibility of a considerable financial return in the way of gate money.

"At a meeting of the Active Rules Committee held in Detroit on June 19 it was the consensus of opinion that decisive action should be had at the August meeting for the restriction of circular track racing. Whether racing of this kind upon mile dirt tracks should be legislated against by the governing body, or whether sanction for circular-track events should be granted only after an entire reconstruction of the track surface and surroundings and some adequate provision other than the use of water has been made for laying the dust, are open questions. In any case. the situation requires decisive action."

Everybody Experimenting with Motors

Recent developments with regard to the sleeve type of motor have uncovered a tremendous line of activity in motor building. It may be said with conviction that practically every manufacturer of automobiles in the world has been experimenting with some new kind of a motor this year.

Many of them are doing this openly, but in the majority of cases the investigations have been carried along with more or less secrecy. In a few instances the fact that the experiments are being made has been officially denied but unofficially confirmed.

The result of course is problematical, but with the adoption of the sleeve motor by several well-known companies, it is apparent that most of the others have been active in looking into the merits and demerits of various sorts of motors not represented by the formal poppet valve types.

Of these there are fifty-five different species ranging through the entire gamut of motor construction. The poppet valve motors generally follow somewhat similar lines and opposed to them is a staggering array of other varieties.

The field of choice offered to the manufacturer is wide and as a consequence the investigation and experimentation have been conducted upon broad lines.

Blue Book Fleet to Rival "Stunt" Cars

With its road work department equipped with three six-cylinder Thomas cars of high power, the Official Automobile Blue Book is about to enter upon its preliminary work for next year. The cars, manned by members of the staff of the publication, will start out this week on tours which for size and length rival the dreams of all the "stunt" car publicity agents rolled into one. The team will cover all the Blue Book routes lying between the crest of the Rocky Mountains and the Atlantic Ocean north of Miami, Florida.

All told, the routes foot up to a total of something over 75,000 miles and in addition to that vast amount of touring the cars will seek out other routes.

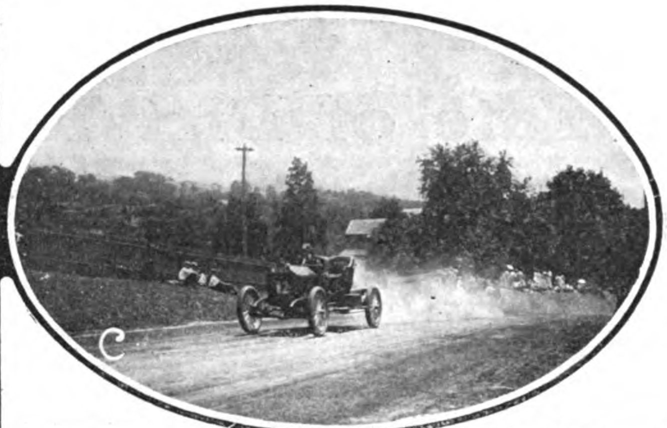
In making these tours the utmost pains are used to localize every landmark, branch road, fork, schoolhouse, cemetery and church so that the users of the routings may have the advantage of the careful work of the map-makers. Every branch road is covered with care, even though it does not form a part of any of the published routes. Every fork is investigated as to where it terminates.

Using a rapid schedule it will require all the time between now and the deadlock of Winter to cover the ground. The reason for this is that every road, whether it is a part of any route or not, is carefully measured with the odometer and checked with other instruments.

It is the announced intention of the management to enlarge and improve the Blue Book of 1912 along the same lines laid down in the current work. This will mean more detailed information about the roads and if possible more complete hotel directions.

T. C. A. Warns of Speed Traps

SYRACUSE, N. Y., July 3—Automobilists of this city and vicinity are interested in the measures that are being taken by the Touring Club of America properly to warn drivers against the existence of speed traps, of which there are a number in this vicinity. They have been springing up of late through the mistaken zeal of that small but troublesome part of motordom known as speed maniacs. The T. C. of A. is taking measures to warn motorists of the traps and at some of them scouts are to be placed on Saturdays and Sundays to issue proper warning to tourists.



A—Paige-Detroit competing in first event. B—At the starting line on Ossining Hill. C—Wilson's National winning the amateur event. D—Summer visitors watched the races with much interest

Nationals Sweep Ossining Card

Indianapolis Cars Win Four Races on Hill

Four events in which they were entered out of five programed at the annual hill climb of the Upper Westchester Automobile Club fell to the lot of National cars on Saturday at Ossining, N. Y. The other race was taken by a Mercer car. There was little sustenance derived by the foreign speed monsters in this hill-climb as the 200-horsepower Fiat finished last in the Free-for-all with a balky carburetor and the special Mercedes could do no better than second in both events in which it started. A big crowd enjoyed the proceedings.

OSSINING, N. Y., July 1—Before a crowd of natives and Summer visitors estimated at about 6,000 persons the Upper Westchester Automobile Club conducted its annual hill climbing contest to-day under delightfully favorable conditions.

The hill was rather easy and was not long and all the cars experienced no trouble in negotiating it. The running off of the card proved to be a clean sweep for the fleet of Nationals that were entered in four of the events. The foreign speed monsters were obliged to bow to the flight of the powerful blue car driven by Len Zengel, who won fame ast Fall by annexing the Fairmount Park Race in a hair-raising finish.

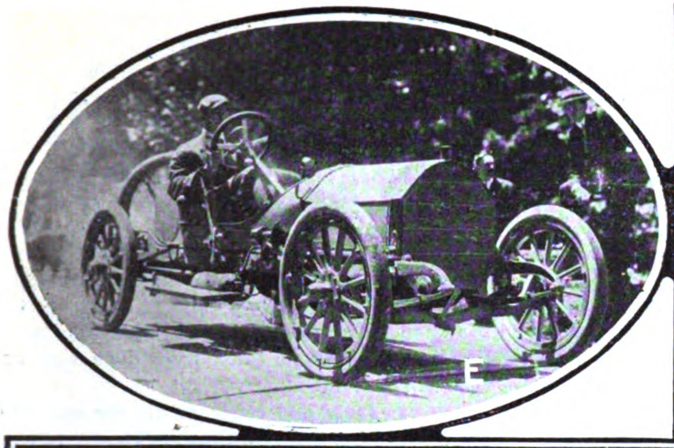
In two events this car was first at the wire, they being its division of Class C and the Free-for-all, in which it defeated such cars as the Arnold Fiat of 200 horsepower driven by Bruce-Brown and the Mercedes monster that ran so well at Indianapolis.

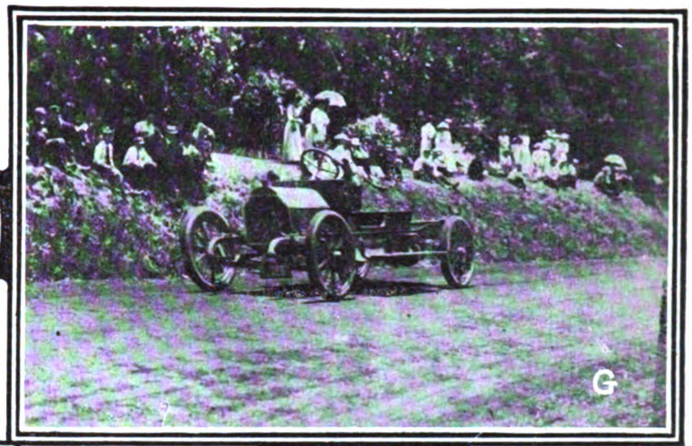
The first race on the program was originally intended for stock cars and was so carded, but its real status was Class E. There were three entries, a pair of Mercers and a Paige-Detroit. Mercer No. 1 proved the speediest and turned the hill in 48 1-5 seconds. The other Mercer was second, four seconds slower and the Paige-Detroit was placed third. The Mercers are considerably larger in piston displacement measurements than the Paige and all three competitors were actually stock cars.

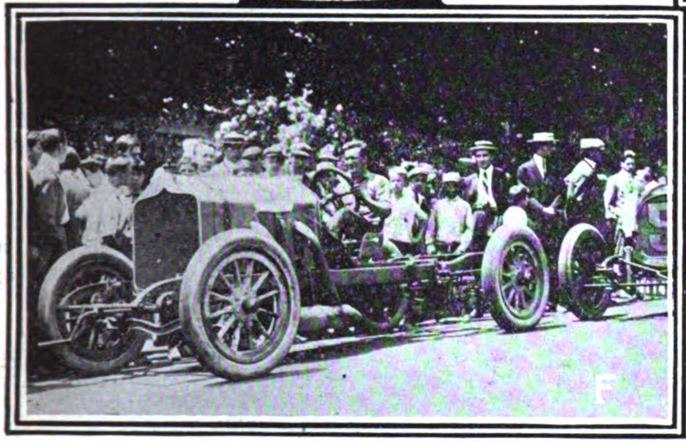
The second race found three Nationals opposed to a Pope-Hartford. No. 4 made a fast climb in 38 seconds and won rather easily, with No. 6 National and the Pope-Hartford separated by only one-fifth of a second for the place. The National that finished last was only three-fifths of a second behind the Pope.

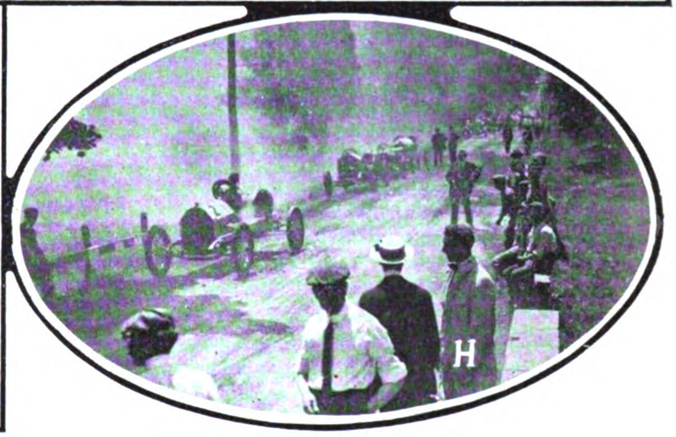
In the race for cars of from 450 to 600 cubic inches piston displacement National No. 8 made the fastest time of the day and won from the Indianapolis Mercedes by one-fifth of a second. The Pope was a distant third.

The club race for cars owned and driven by members of the Upper Westchester Automobile Club attracted only three starters. National No. 12 finished the climb in 45 1-5 seconds, beating the Stearns and the Mercer. There were handicap con-









E—Winning Mercer car in event No. 1. F—Double winner of the day, a National. G—Stearns car made a good showing in club event. H—When the word was given to start in one race

ditions in this event but they did not serve to alter the placing of the cars.

The big race of the day was the Free-for-all, last on the program. In this there were five starters including two Fiats, Mercedes, Pope and National. The latter equaled its fast run in the class race mentioned above, 33 4-5 seconds. The second car turned up in the Indianapolis Mercedes, one second slower, while the fully equipped Fiat car, No. 14, was third in 37 1-5 seconds. The Pope came fourth and the big Fiat, coughing and sputtering with carbureter trouble, just managed to wabble past the finishing line in 42 4-5 seconds.

The event had a distinct flavor of finance about it as three of the competing drivers, all of whom hold professional credentials, are rated above the million-dollar mark. They are: Bruce-Brown, Wishart and Bragg. Three other drivers are also considered rich men in a comparative sense, Disbrow, Rutherford and Sherwood.

The hill is hardly long enough and difficult enough to afford a setting for a hard test. It is not equal in any way to Sunset hill that has been used heretofore. The starting point was at the limits of the village of Ossining on the north side and the course was laid out 2,814 feet toward the center of town. The whole hill has an average grade of 6 1-2 per cent. and a maximum of 11 1-2 per cent. There is one curve of about 15 degrees.

There was nothing that looked like an accident during the afternoon and the races were conducted with commendable speed after the first car was sent away. A. F. Camacho represented the Contest Board and A. J. McShane was referee. The summary:

Class E, Special for 160-300 Cars

Number	Car	Driver	Position	Time
1	Mercer	Van Wyck	1	:48 1-5
3	Mercer	Sherwood	2	:52 1-5
2	Paige-Detroit	Craig	4	:58

Class C, Division 4, for 301-450 Cars

4	National	Bragg	1	:38
6	National	Rutherford	2	:39 4-5
5	Pope-Hartford	Disbrow	3	:40
7	National	Tierney	4	:40 3-5

Class C, Division 5, for 451-600 Cars

8	National	Zengel	1	:33 4-5
9	Mercedes	Wishart	2	:34
5	Pope-Hartford	Disbrow	3	:41

Class E, for Cars Owned and Driven by Members of Upper Westchester A. C.

12	National	Wilson	1	:45 1-5
11	Stearns	Wallace	2	:47 2-5
3	Mercer	Sherwood	3	:51 2-5

Class D, Free-For-All

8	National	Zengel	1	:33 4-5
9	Mercedes	Wishart	2	:34 4-5
14	Fiat	Stuart	3	:37 1-5
5	Pope-Hartford	Disbrow	4	:40 1-5
15	Fiat	Bruce-Brown	5	:42 4-5

Newark Club Plans for New Home

NEWARK N. J., July 3—The New Jersey Automobile and Motor Club has inaugurated a campaign to raise $25,000 for the erection of a country clubhouse. The plan provides for a nine-hole golf course. Several sites, within a short run of Newark, are under consideration. The club's present lease on the Lake Apshawa club house expires in 1912.

The contest committee of the organization is arranging for an endurance run to take place in September. While nothing definite has been settled on, the affair, it is said, will be either a twelve-hour or twenty-four-hour contest.

Foster to Spend $200,000,000 on Roads

PITTSBURG, July 3—County Road Engineer S. D. Foster has recently been appointed first assistant to E. M. Bigelow, Chief Road Engineer of Pennsylvania, who will have charge of the expenditure of more than $200,000,000 for good roads in the Keystone State. It is likely that the Automobile Club of Pittsburg will take action expressing regret at his departure at the next meeting. Before Mr. Foster's leaving the employees of the county engineer's office presented him with a fine gold watch and fob.

Big Crowd Sees Mile Record Fall

Brighton Beach Two-Day Meet a Success

Seventeen races, practically all of which developed a struggle somewhere in their various courses, as well as a mile trial against time that set a new mark for the distance, were the offerings set before the public at the two-day race meeting that was held at Brighton Beach July 3-4. The keenest and most spectacular of the struggles that were staged came in a race that gave little promise of any such thing, the free-for-all handicap of July 4, when an E-M-F racing car just lasted long enough to nose out a Pope-Hartford in the most remarkable finish ever made at the track.

TO a full house the automobile racers played on Independence Day at Brighton Beach. The crowd of 5,000 persons who witnessed the races on the preceding day was tripled in honor of the holiday and all around it was a delightful and successful day's sport. There were seventeen races decided during the two days and for good measure the one-mile circular dirt track world's record was lowered by one-fifth of a second. Not an accident marred the sport during the running of the cards.

The feature race of the meeting was the struggle for the Remy brassard and the $75 a week that goes to the driver of the winning car and as was predicted in THE AUTOMOBILE the big end went to the big special Benz car and the $75 a week must be paid to Burman, unless he has some arrangement with the manager of his stable by which the "salary" will go into the stable's treasury to pay railroad fares and such things.

The "stable" which is managed by E. A. Moross, who also promoted the race meeting, did very nicely all told. Besides the brassard race, two Class E races were won by its representative in the person of another Benz car driven by Patschke. In the bigger division of this class, however, something must have slipped for Simplex 2 took down first money on the opening day and National 33 gathered the shekels on July 4.

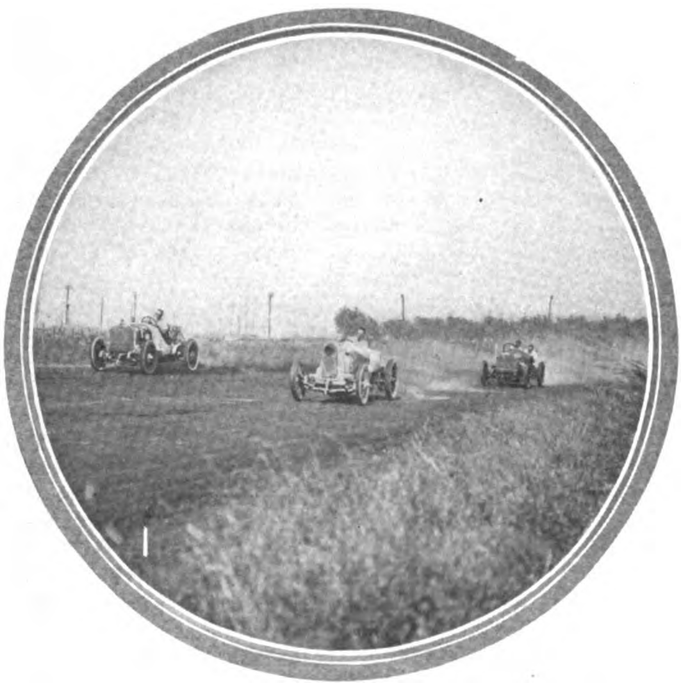
Despite these drawbacks the stable must have done well because the "gate" was satisfactory.

There were no stock car races and consequently the spectacle afforded was simply a spectacle, but it was a mighty interesting one.

The first event of the first day attracted a field of seven starters. The E-M-F entry got away flying and won all the way by a fair margin. Paige-Detroit 29 broke second and followed the pace for nearly 2 miles, when it gave way to the Lancia. At the finish the winner was eased up in 5:43.86 and the Lancia took the place handily. All three Paige cars finished.

Event No. 2 was for Class C cars of division 3, 231-300 cubic inches piston displacement at five miles. Five cars appeared on the starting line, two of the scratched cars being S. P. O. 14 and Mercer 31, the drivers of which had met fatal accidents before the opening of the races. The Mercer contestant had the speed of the party and led from end to end, winning in the fast time of 4:55.51. Correja 8 was second all the way and S. P. O. 15 worked its way into third position at the end. The Schacht did not have its burst of speed and the Marion went out with tire trouble.

The "stable" got its first taste of glory in the next race which was for Class E cars, 301-450 cubic inches displacement. Two Nationals, a Benz and a Jackson formed the field. National 10 took up the pace in the early stages and appeared to have the foot of the party. But in the fourth mile the Benz came along under Patschke's handling and nipped the contender. The Benz went on to win handily in 4:42.47. The Jackson suffered with ignition trouble and was never prominent.



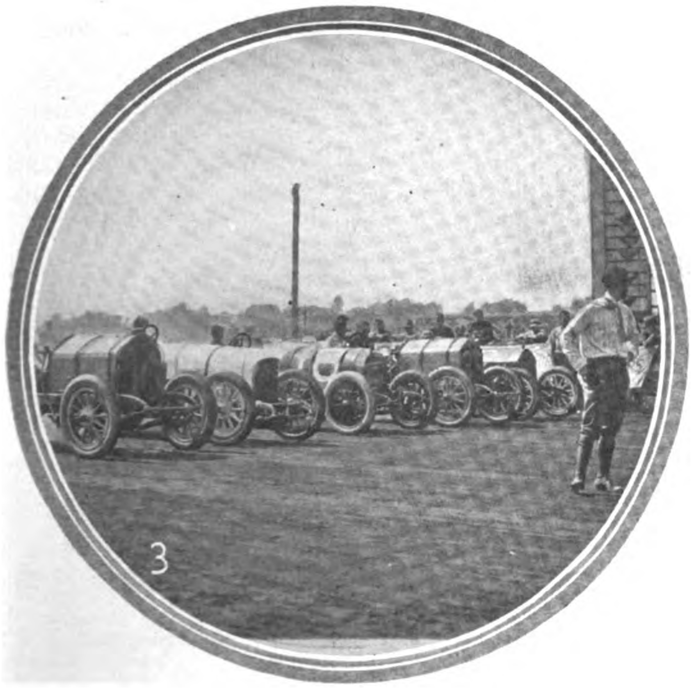
1—Making the far turn in the first heat of the Remy Brassard race

2—How six thousand spectators viewed the Independence Day races

Simplex 2 had a nice easy run in the next number, winning from three Nationals and the Benz car that got the purse in the foregoing event.

The novelty race developed no novelties and not much of a race. The cars were required under the rules to load passengers at the end of the first mile, discharge them at the end of the second; load them at the third; discharge them at the fourth and finish without passengers. A Hudson car had too much speed for the Colby that contested against it. The Hudson won in 8:11.56, including the time lost in making the four stops and five standing starts.

Next came the first heat of the Remy brassard race at three miles, flying start, free-for-all. Five cars faced the starter, including the Blitzen Benz, plain Benz and Mercedes, from the

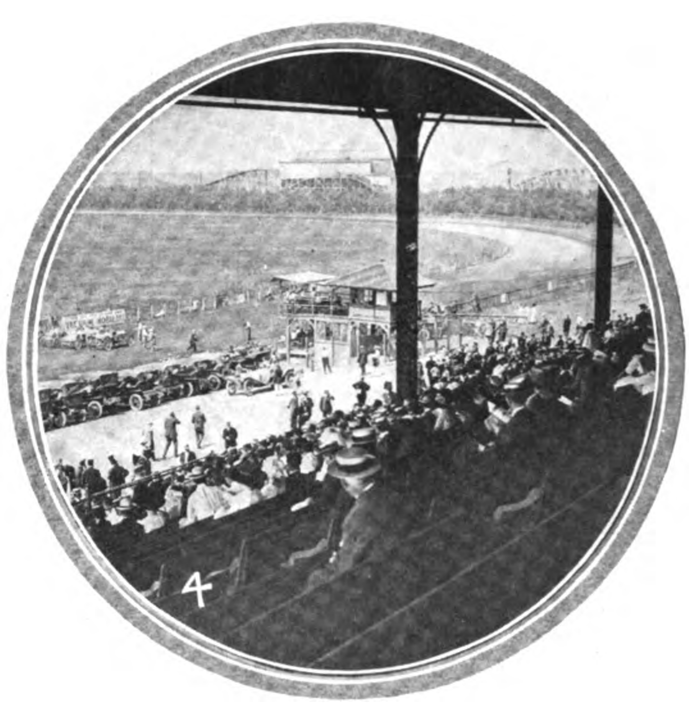


3—Line-up of the cars in Event No. 4, on the first day

Moross stable; National 33 of the Poertner Motor Car Company and Simplex 2 from the Simplex Automobile Company. After one false start, the cars came down to the line in a fairly good rank and the red flag signaled them to go. The plain Benz soon settled into a short lead, taking the pole position while out toward the center of the track the Blitzen lay second. In behind the leader, the Simplex ran along in third place, pocketed from wire to wire in such a way that, skillful driver though he is, De Palma could not get through. The others trailed throughout. The plain Benz finished first by a short margin with the Blitzen second and Simplex third. The time was 2:41.68.

Simplex number 20 was eligible to start in this event but the driver's card held by Ormsby had been suspended by the referee for the part the driver had taken in the accident that led to the death of H. Frey earlier in the day and the destruction of Mercer 32.

Event number 7 was changed from a one-hour race to a grind of 60 miles and drew out a fine field of eight starters. Simplex 2 won all the way without being extended. Second place went to Mercer 32, which worked its way up from fourth position. It was about 2 miles behind the winner and 1 1-2 miles ahead of Marion 13, which came third. The race was marked by a bit of sensational driving on the part of the pilot of Pope-Hartford 18. Disbrow blew a right rear tire making the paddock turn in the thirty-eighth mile and managed to bring the big machine to a stand just touching the fence after a plunging flight along the rail for over a furlong. The car was set going again in a short time and was a factor until the beginning of the final spurt, when tire trouble retired it.



4—The grandstand was not crowded on July 3

The trophy in this race was the W. B. and $100 in gold.

The last event of the day produced an unusual mixup and an unusual ruling on the part of the officials. It was a free-for-all handicap in which 14 cars presented themselves for the start. The word was given to the three Paige-Detroits which were to receive the limit handicap and when the Paiges started, six other cars went along. At the end of the mile it looked very much like a jam but the net results were the loss of a wheel by one of the Paige cars. The referee then refused to allow any of the six cars that had taken part in the breakaway to compete. These were the Crow 5; Correja 8; Marion 13; S. P. O. 15; Lancia 16 and E-M-F 19.

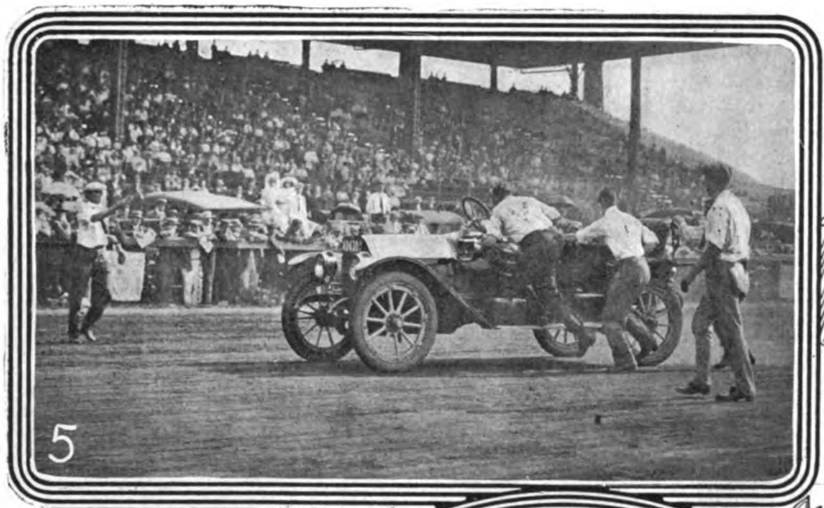
The race proved rather easy for Mercer 32 with Simplex 20 second and Pope-Hartford 18 third. Time 5:33.53.

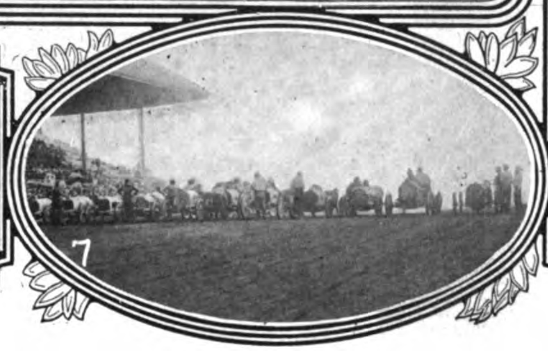
On July 4, the big Benz, under Burman's handling, lowered the dirt track record one-fifth of a second and won the Remy brassard by taking two successive heats from the plain Benz. Patschke, driving a dark horse known as the Jenatzy Mercedes, made one surprising spurt in this event and for a moment headed his colleagues on the far turn. The Jenatzy, however, was not up to much and flattened out after that single flash.

The card included a free-for-all handicap which was won by the E-M-F by the length of its hood from the fast coming Pope-Hartford. The brush through the stretch between these two cars was the closest and most terrific bit of driving of the afternoon. The handicap of the E-M-F was sufficient to give it a start of practically half a mile and as the pace was rather easy in the first two miles the Pope-Hartford had to come with keen speed to draw the finish so close.

The Correja won Class C, Division 3C, event with ease, finishing ahead of the Marion and Crow.

The Prince Henry Benz had a cake-walk in the fourth event, but National 33 defeated it and several others in the next class. Then came the foreclosure of the mortgage on the brassard as stated. National 33 won the Australian pursuit race after a fierce struggle. National 10 was put out first in this race by being passed by Simplex 20 and, in turn, National 33 put out the Simplex. This left only the Pope-Hartford and National 33 in the race and after a fierce drive of 23 miles the Pope blew a tire in front of the stand and in sight of 15,000 people the pilot racked the steering wheel in response to the reeling of the wounded car and brought it to a safe stop in front of the judge's stand.





5—Passengers scrambling into the Hudson, winner of the novelty race
6—Line-up for the 301-450 race on the first day—Benz, two Nationals and a Jackson
7—Start of the 60-mile race, which was won by the Simplex, Mercer second, Marion third
8—The E-M-F, Jack Tower driving, which won three races

A small class race was won by the E-M-F which was not on the program and was probably inserted to make up for the fact that most of the cars that took part had been barred from the free-for-all handicap of the previous day.

One of the most interesting races of the meeting was the last one carded for July 4. It was at 50 miles and brought out a field of six. Pope-Hartford won rather handily after the two Nationals had succumbed to tire trouble. The Jackson car was second and the Crow, carefully and conservatively driven by Otto F. Rost, General Eastern Agent of the company, was third, The Crow did not go to the pits for tires or anything else and was running considerably faster at the finish than earlier in the race. It was last to get away and maintained a steady pace all the way through and as one car after another went out from tire or motor troubles it forged toward the front. At the rate the last 10 miles were run, it would have won had the race been 60 miles long.

JULY 3—FIRST DAY

Division 2C for cars of 161-230 cubic inches, Five Miles.

Number	Car	Driver	Position	Time

Will Handle American and Marion

Papers have been filed in Albany for the incorporation of the American-Marion Sales Company, a $100,000 corporation to handle the American and Marion cars in the Metropolitan district. The incorporators are: James I. Handley (formerly vice-president of the U. S. Motors), Chas. E. Riess, distributor of the Marion cars, and Geo. R. Morris, at present general manager for Chas. E. Riess & Co.

Missouri Licenses to Come Down

St. Louis, July 3—A general reduction of the price of automobile licenses is in prospect for St. Louis. A law passed by the last legislature regulating the State charge makes it incumbent on cities to charge no more than is authorized under the State law. For years the rate in St. Louis has been $10 for each car, regardless of the size, type or horsepower. Under the new law the average charge will be about $5. There have been 4,632 licenses issued in St. Louis so far this year.

The new law goes into effect Aug. 1. The city's lawmakers are expected to pass a new ordinance covering the situation before that date.

New Electric in the Field

Louisville, July 3—The Electric Vehicle Company, which will manufacture electric trucks, has opened its new plant at Preston and College streets. Later the concern will build electric pleasure cars. The new plant, which is the first in Kentucky to manufacture electric cars, covers 20,000 square feet of floor space. All of the machinery has been installed and the capacity of the plant at present will be about 100 cars each year. Those interested in the new company are Lee Miles, of the Miles Auto Company, E. M. Drummond and H. B. Hewitt, who has been connected with the Cooper-Hewitt Company.

A panel-delivery standard body, with other types optional, will be used on both the 600 and 1,000-pound vehicles. The silent chain drive has been adopted. A wheel base of eighty-six inches is used. Fully loaded the trucks are capable of traveling from 12 to 15 miles per hour.

Premier Caravan on Westward Way

Indianapolis, Ind., July 5—After two days of feasting and sight-seeing in Indianapolis the sturdy Ocean-to-Ocean Premier tourists again turned their faces westward this morning. The first 1,000 miles of the long journey, from Atlantic City to Indianapolis, were accomplished with no more wear or tear or mishaps than are generally encountered. The big party of Philadelphia and New York business men, with their families and friends filling eleven cars, were as enthusiastic as children just out of school and all were confident that the tour would be a success.

The Northern route across the Great American desert will be followed, Chicago being the next stop on the schedule after the departure from Indianapolis. From Chicago the route lies through Des Moines, Ia., Omaha, Denver, Cheyenne, Salt Lake City, Reno, San José, San Francisco, Santa Barbara and Los Angeles. The tourists are due to arrive at the latter place September 10.

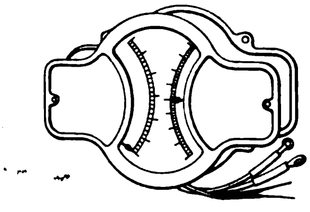
Seen in the Show Window

KNOWING a situation is equivalent to being able to describe it, and controlling the powers of nature includes not only their utilization, but also the possibility of measuring their amounts and intensities. This being true and applied to that most popular energy, electricity, it is seen that the many ways in which it is utilized to-day have brought about the construction of almost as many sorts of instruments of measuring and controlling that force, the fundamental of these appliances being voltmeters and ammeters. Since automobiles, at the present time, use considerable quantities of electricity, for propelling cars, igniting a mixture and illuminating the machines at night, it was only natural that special types of instruments for measuring the energy used in the work of charging automobile batteries were constructed. One of the up-to-date results of these efforts is illustrated at (AK), this being the volt and ammeter of the Weston Electrical Instrument Company, whose factory is at Newark, N. J.

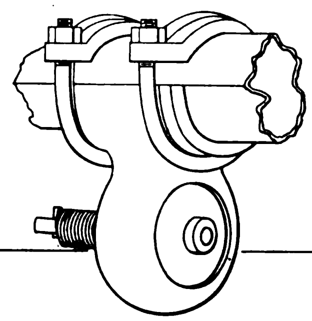
TO increase the driver's efficiency as well as his good disposition is a proposition which cannot but interest the gentleman automobile owner, and the little step in the forward direction which will bring him to the end desired is the acquisition of an electric lamp ignitor, an example of which, the Hart Instantaneous Gas Lamp Ignitor, is shown at (AM). By means of this device the driver, after opening the way for the acetylene to the headlights, ignites the gas without leaving his seat, by the simple expedient of pressing a button or turning a key, whereby a circuit is closed and a battery in conjunction with a sparking coil produces a spark above the acetylene burner, which is sufficient to instantly ignite the gas. This igniter is made by the Hart Gas Light Igniter Company, of Hartford, Conn.

THERE are occasions where the cut-out comes in handy, as in starting up a hill, and the silencing effect of the muffler will have to be sacrificed at such times for the utilization of what otherwise makes itself felt as back pressure. The S. B. R. Muffler Cut-out is illustrated at (AL), and being of simple construction, it is easily installed on a car in the minimum of time. The cut-out valve seen at the lower portion of the device, and which has a ground seat with spring holder, is operated from the dash by a pedal in the usual manner. This appliance is the product of the S. B. R. Specialty Company, of East Orange, N. J.

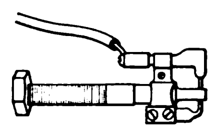
AK



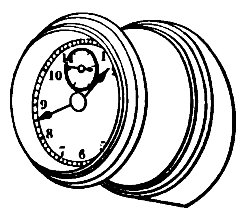
AL



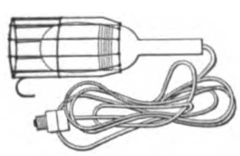
AM



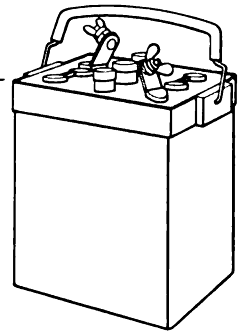
AN



AO



AP



AK—Type of volt-ammeter for various uses in connection with automobiles
AL—Illustrating one of the latest types of muffler cut-outs
AM—Enables the driver to light his lamps without leaving the seat
AN—Keyless dash clock which will prove a convenience for automobilists
AO—The Morse special type of portable electric lamp for garages
AP—Outward appearance of the Geiszler storage battery

STORAGE batteries are used on automobiles for several purposes, and, judging from present tendencies, the number of their applications in this field seems to be still on the increase. Compactness and efficiency, together with a relatively high capacity, are the main features looked for in batteries, but there are also some points of chemical rather than physical nature, these being the degree of sulphation that the various types of accumulators are subject to. The Geiszler storage battery, an illustration of which is here afforded (AP), is claimed by its makers to be non-sulphating, and the manufacturers guarantee that the battery will not deteriorate while it stands idle. It is manufactured by the Geiszler Bros. Storage Battery Company, whose address is 1512 W. Fifty-seventh street, New York.

TOO many accessories crowded on the dash may be a nuisance, but just because this is so it will be necessary for the autoist to weigh out carefully the importance of all the various devices which may be placed there, before deciding to eliminate some of them therefrom. Every motorist will grant that having the right time before him is a very desirable state of affairs, because a clock on the dash will never be considered a nuisance if compared to the timepiece which is carried in one's pocket and is hard to get at when driving. The Perfect Auto Clock, which has a Seth Thomas movement contained in its makeup, is shown at (AN), a special feature of this clock being that it is not wound up by means of a key, but the bezel is turned around once a week. This strong little piece of machinery is made by the Phinney-Walker Keyless Clock Co., of 77 E. 130th street, New York.

ELECTRIC light must necessarily be used all over in garages, and it is found in the important regions of these establishments; but the employees are not very frequently equipped with portable lights permitting of looking over any parts of a car without using any other illumination but an electric bulb. A special type of garage lamp is made and sold by Frank W. Morse of 516 Atlantic avenue, Boston, Mass., the lamp being shown at (AO). It consists of a vapor-proof globe containing a 16-candlepower lamp, a waterproof socket in handle, silvered guard and reflector, together with 12 feet of slicked cord and a two-piece plug. A special feature of this lamp is its being perfectly proof against combustible vapors.

VOL. XXV. NEW YORK—THURSDAY, JULY 13, 1911—CHICAGO No. 2

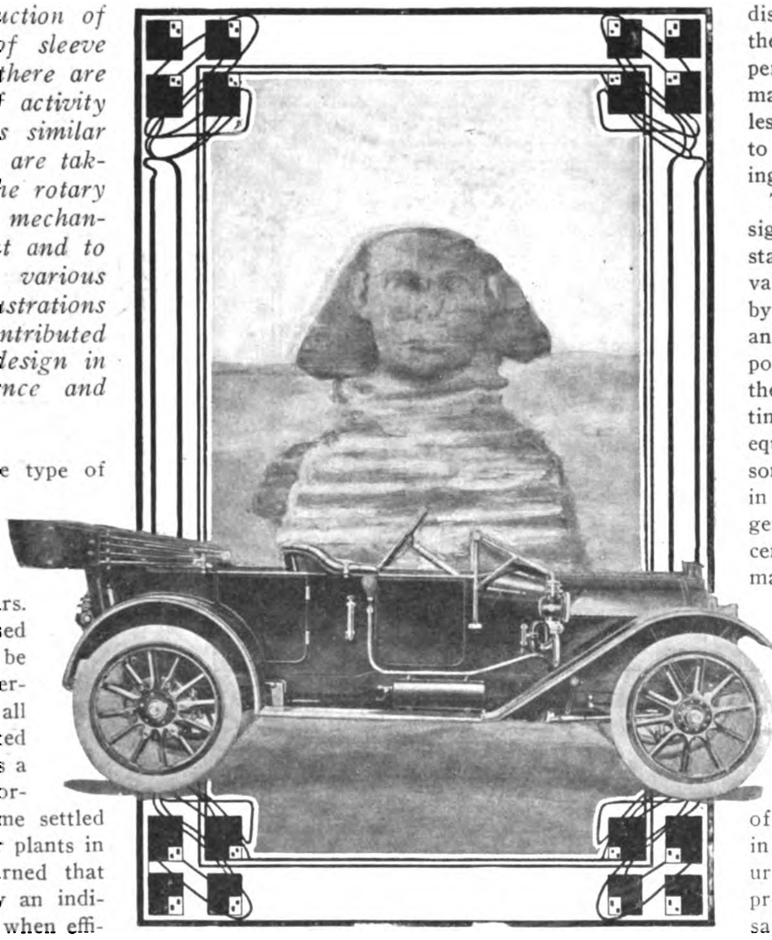
THE AUTOMOBILE

What Motor Inventors Are Doing

Quest for Silence in Devious Ways

Following the introduction of the Knight type of sleeve motor in America there are many indications of activity along more or less similar lines, and inventors are taking advantage of the rotary principle of valve mechanisms to some extent and to sliding valves in various forms, and the illustrations here afforded are contributed by one school of design in the quest for silence and efficiency.

WHEN the sleeve type of motor was first presented to the notice of the builders of automobiles it fell upon deaf ears. It was not then supposed that a machine could be built so that it would perform silently, and in all fairness noise was courted on the ground that it was a good indication of a vigorous power plant. As time settled upon the ability of power plants in general, and it was learned that noise was not necessarily an indication of power—in fine, when efficiency became a factor in the enterprise and the twins of merit were looked upon as the progeny of silence and efficiency—the desire to get away from the causes of noise and power losses took root in the thoughts of designers; the automobile industry has so far progressed that the supporters of the industry are putting a premium on silence, and it would be difficult to disabuse them of the idea that where silence reigns efficiency is absent.



IN THE COMPETITION FOR SILENCE

It would be difficult to state how many of the makers of automobiles of to-day are working upon the various types of motors that do not depend upon poppet valves for their performance. Moreover, it may be truly stated that every maker of cars who puts faith in poppet valve mechanisms is re-designing the parts on a basis of silence as the prime consideration, and it is doubtless true that when the valves do their work noiselessly they function efficiently also. It is more than likely that the best testing instrument available to the mechanician may be known by the appellation of "kinetic silence," the attempt being made here to distinguish between the static and the kinetic condition, with the hope, perchance, that the silence of the machine as it rests in its motionless static state will be transferred to the time when the motor is doing kinetic work.

There are many schools of design in motor building, and the staunch advocates of the poppet valve type of motor are proving by their work that silent performance is no stranger to a well-made poppet valve type of motor, nor is there any indication at the present time that these sturdy power equipments are to be supplanted by something new. It has been said in recounting business ventures in general that upwards of 94 per cent. of all the efforts that are made end in failure, and that a sparse 6 per cent. of industrial activity ends in success. Of the many undertakings in the motor field that have for their foundation the building of something new, it is not too much to expect that the customary percentage of the whole effort will go down in history on the carry-all of failure, and it is the purpose in this presentation to save time and the sap of investment by telling the various designers of the efforts that are being made in this field, avoiding, in so far as it is possible to do so, the praising of individual undertakings until it can be shown by actual trial that they will survive the "acid" test.

How the Various Designers Approach the Difficult Problem of Motor Building

Before passing on to the discussion of the types of motors that differ in principle from the Knight design, it is proposed to show by illustration and reference the modifications of this idea as they obtain in Continental makes of motors, and Fig. B is an elevation in part section of the Panhard-Knight motor as made by Panhard & Levassor, Paris. In this elevation, which is of the left-hand side of the motor, the front cylinder is given in section, showing the main bearings M1, M2, and part of the middle main bearing M3, the latter being provided with means for taking the thrust imposed upon the crankshaft. The connecting rod C1 has a liberal size of large end bearing M4, and the piston H has three rings h above the gudgeon pin. Attention is called to the inverted sphere-like head of the piston, and the fact that one of the piston rings h is in the body of metal forming the wall of the piston above the plane of the inverted sphere-like head. Among other possibilities it is more than likely that the designer of this motor figured upon the insulating quality of a layer of dead gas in the cup formed in the piston head, but this depression is also indicated period of combustion. In this particular design of motor a single spark plug is inserted in the axis of the head, but the provision for cooling in the region of the spark plug is on a liberal basis.

The eccentric shaft L takes its power from the crankshaft through the pinion G by means of a silent chain to the gear K. The sleeves N and N' have motion imparted to them through the connecting rods M and M'. The shrouded pulley V on the end of the crankshaft takes a belt for use in driving the air propeller. The crankshaft is flanged at the rear end and the main bearing M5 is of unusual length and has a liberal projected area.

Referring to Fig. C of the Panhard-Knight motor, the contour of the inlet and exhaust ports is sweeping and smooth, terminating in symmetrical lips of the inlet and exhaust ports, and when the piston H is on the top dwell point, the space between the shell of the piston head and the inmost point of the cylinder

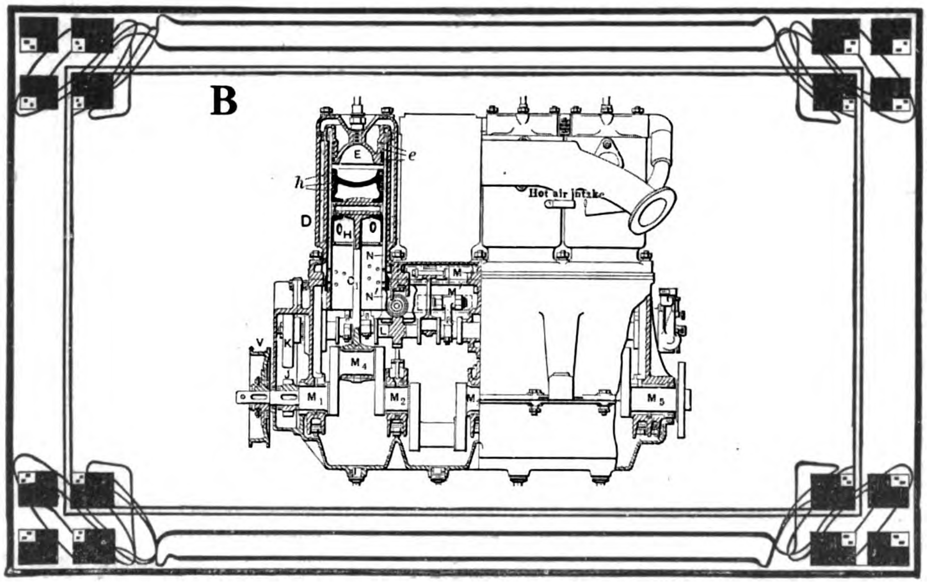


Fig. B—Sectional view of the Panhard-Knight motor, showing the relation of the sleeves, the spherical piston, and the method of operating sleeves

by the necessities of a proper compression ratio dictated by the fact that the cylinder head inserts into the cylinder and a considerable amount of the diametral space is occupied by the walls of the head, accommodating a junk ring e, not forgetting that the sleeves are in the concentric relation with the cylinder, also the piston, and the part of the head that extends down into the cylinder, so that the compression space E formed in the head would scarcely suffice in view of the requirement, and it therefore follows that the depression of the piston head offers the advantage of regulating the compression ratio without the necessity of exposing the walls of the sleeves to the flame during the period of combustion. We do not call to mind that anyone has heretofore pointed out that the sleeves of the Knight motor are protected from the fierce glare of the flame during the head is barely sufficient to uncover the slots in the sleeves, and the packing rings n_1 and n_2 on the inlet side, co-operating with the slots in the region of the exhaust port, imprison the mixture under compression within right confines, and leakage is substantially avoided. In examining this section of the cylinder in the region of the lips of the ports we do not find the same careful attempt to maintain cool conditions as is shown in some of the other examples of this same make of motor, although the excess of metal forming the lips of the ports is in close relation to the water in the jacket, the difference being due to the extension of the lips for an unwatered distance, and the bunching of metal, due to fillets, that must obtain under foundry conditions in a design so made. The carbureter is located on the right side of the motor and the intake I1 is of somewhat symmetrical

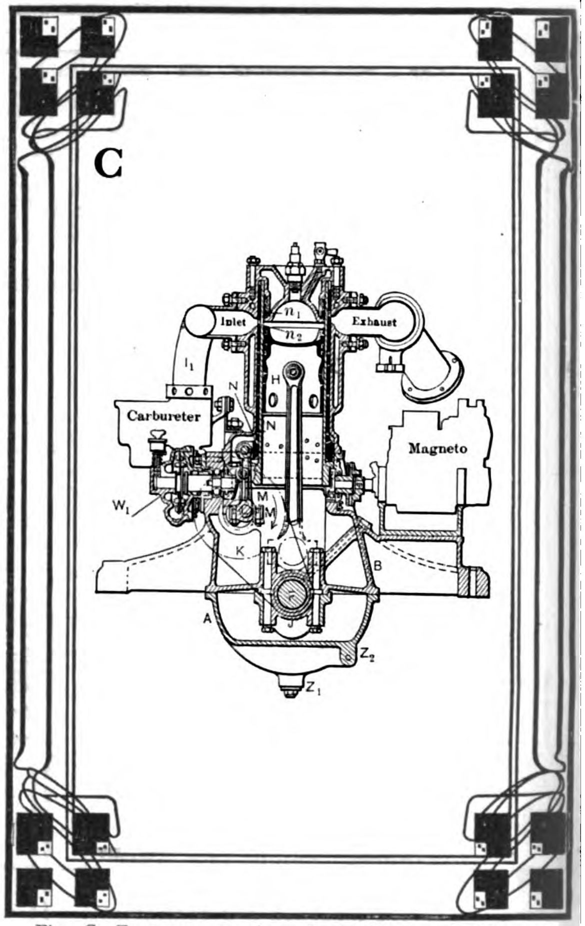

Fig. C—Transverse section of the Panhard-Knight motor, showing the small connecting rods that operate the sleeves and the cup-shaped piston

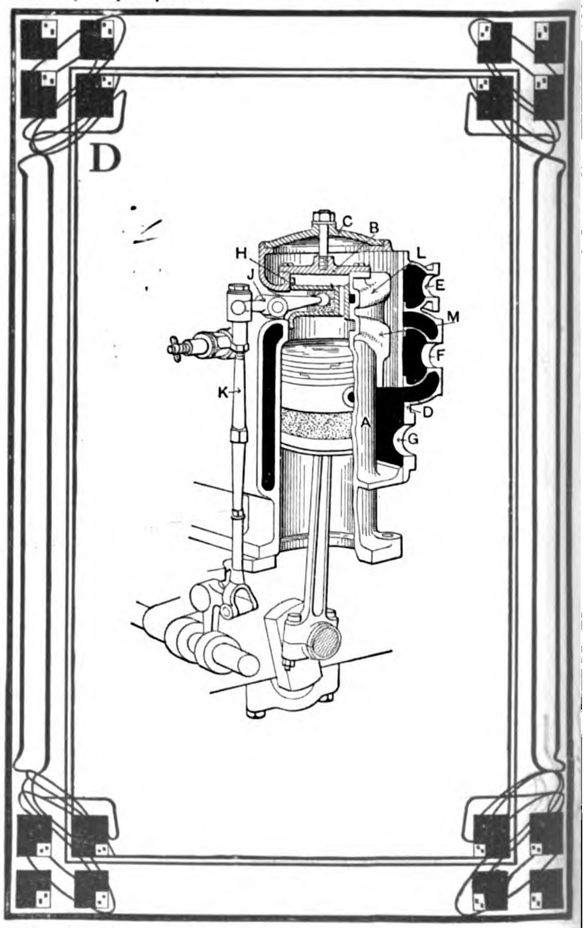

Fig. D—Showing the Reno Bois motor with part of the water jacket removed, together with the valve operating mechanism.

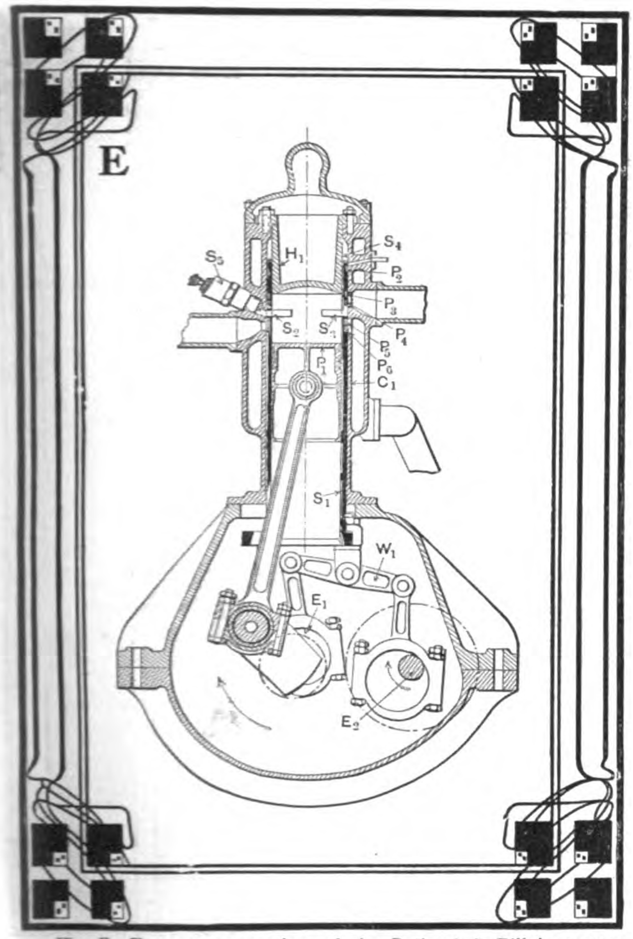

Fig. E—Transverse section of the Rolland & Pillain motor, showing the method of operating the single sleeve and the location of the spark plugs

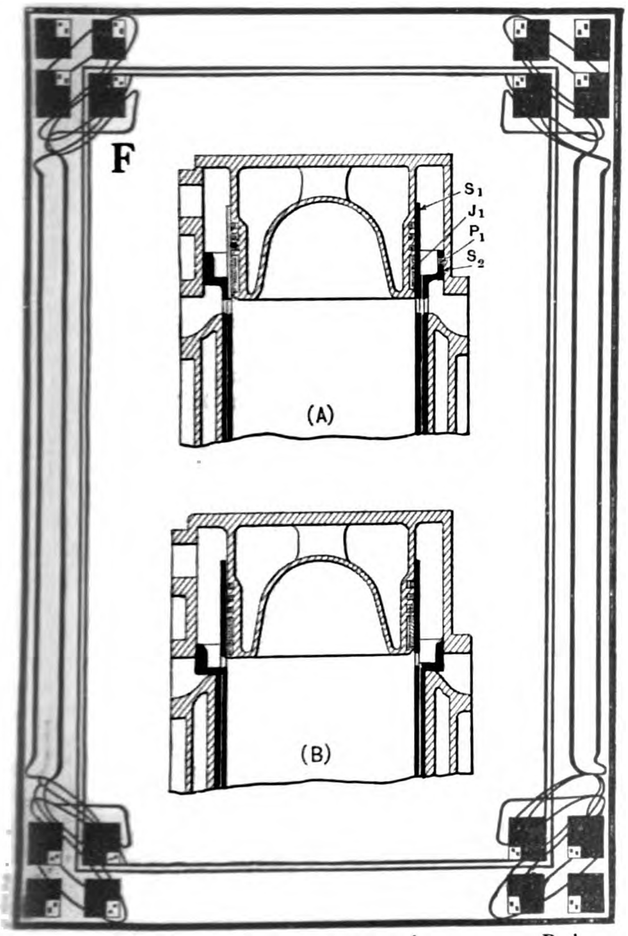

Fig. F—A shows section of motor with sleeves open. B shows position of outer sleeve when valves are closed

design, with an upward trend for a material distance before it branches out through the distributing arms to the respective cylinders. The magneto is on the opposite side of the motor, taking its drive from a cross shaft, the latter being driven through the good office of a spiral gear located between the first and the second cylinders on the eccentric shaft.

The water pump W1 is shown in section on the right hand side of the motor and is driven by an extension of the cross shaft in the plane of the magneto drive; an Oldham joint is placed in the length of this shaft at the approach of the water pump. Referring to the joint in the shaft as it extends to the magneto, it is of the dog type, and the magneto resting on a ledge extending out from the crankcase may be unbolted and removed at will without having to undo the joint, thus making for easy examination and repair.

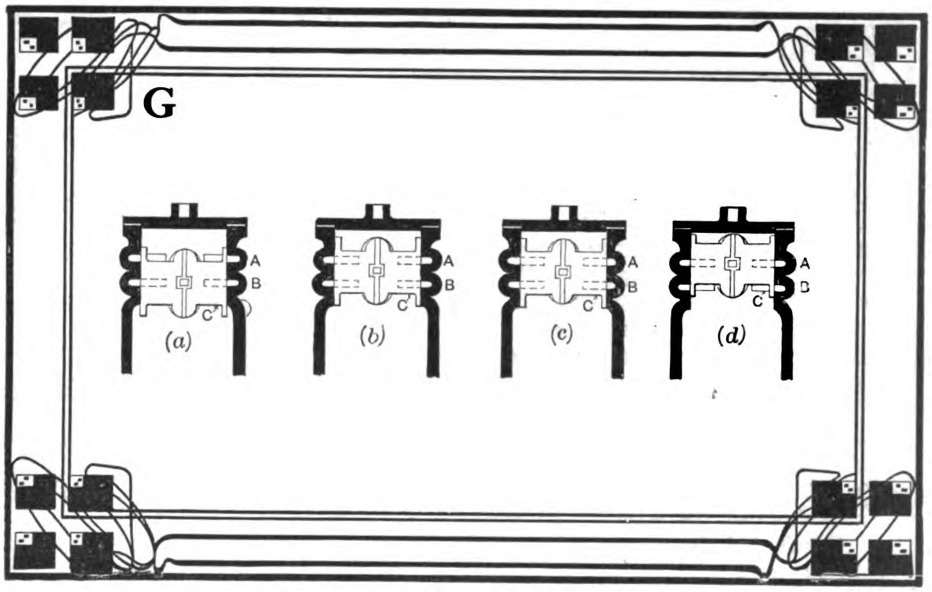

Fig. G—Section of the Reno slide valve engine showing induction, compression, firing and exhaust strokes respectively

How the Reno Bois Place the Sleeves in the Cylinder Head

Fig. D, which is a part section through the cylinder of the Reno motor, is a clear presentation of the idea instilled in this design, showing the crankshaft in the crankcase in the customary way and the connecting rod joining the crankpin to the piston through the gudgeon in the regular way, the valve mechanism being placed in the cylinder head, which by letter reference is described thus: The valve gear consists of a split ring H fitting closely in the cylinder head and provided with a bearing block which is engaged by the rocking lever J, which in turn is operated by the tappet K. This tappet is raised and lowered by means of a short bell crank, one leg of which engages the tappet, and the other a double-faced or channeled cam carried on a camshaft parallel with the crankshaft.

To allow the rocking lever J to pass into the cylinder a slot is provided in the latter, which is always covered by an extension of the ring valves whatever the valve position. The split ring valve in its travel moves over the annular chambers L and M, which are cast in the cylinder wall and form the inlet and exhaust ports respectively, these ports being in communication with the inlet or exhaust trunks E and F.

The diagrams (a) (b) (c) and (d) in Fig. G show the valve in the induction, compression, firing and exhaust positions, the inlet port E (Fig. D) and the exhaust port F being shown uncovered during the induction and exhaust strokes, and both covered during the compression and working strokes. A (Fig. D) is the cylinder casting with a detachable head B, the central bolt of which holds the water jacket cover C. The side plate D carries the inlet union and chest E, and the exhaust trunk and union F, also the water connection G. The report of the performance of a motor of this design with a bore of 85 millimeters and a stroke of 130 millimeters states that the motor delivers 28 horsepower at 1,350 revolutions per minute, and it has been stated that this is the speed of greatest stability, although the motor accelerated during the test up to 2,200 revolutions per minute.

Rolland & Pillain Single-Sleeve Motor

A motor that performed favorably under racing conditions in France within the last two or three months, the Rolland & Pillain, is shown in Fig. E with the sleeve S1 concentrically related to the cylinder C1 and the piston P1 with slots S2 and S3 in the sleeve and a depressed head H1, leaving a space S4 between the

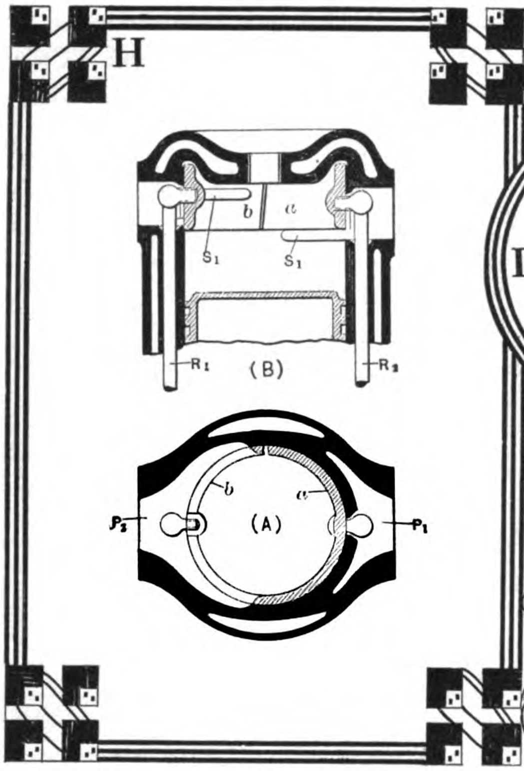

Fig. H—Sectional view of the Howard sliding sleeve valve motor utilizing a spherical split ring

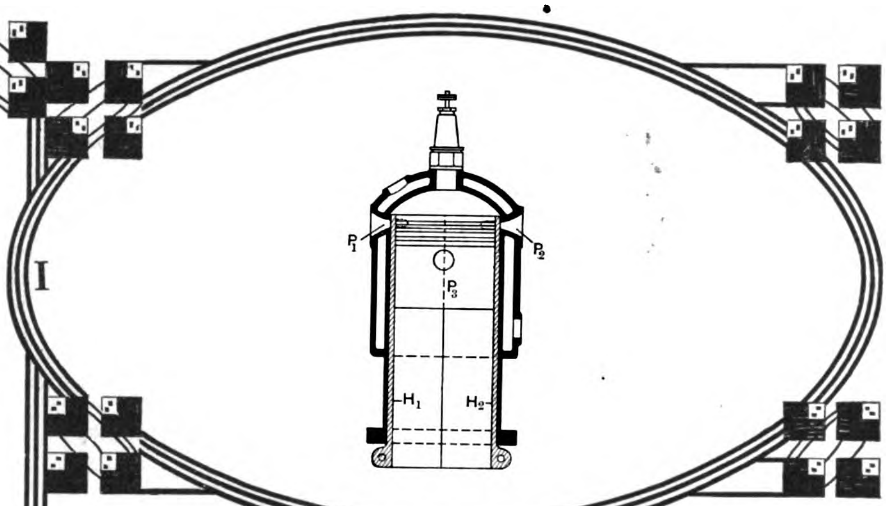

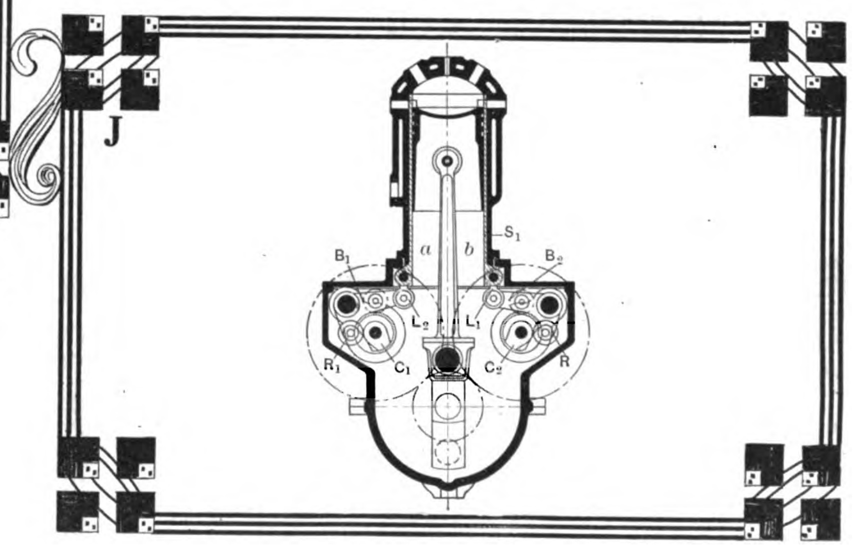

Fig. I—Transverse sectional view of the Redrup motor in which two hemispherical sleeves cover and uncover the valve ports

Fig. J—Transverse section of the Mustard motor, showing how the two hemispherical sleeves are operated by means of cams and rollers

cylinder wall and the head to accommodate the sleeve in its reciprocating relation, with packing rings P2, P3, P4, P5 and P6, in the sleeve to maintain good compression, and the spark plug S5 so located that firing must take place during the period of uncovering due to the slot in the sleeve, shutting off the spark when the port closes. The sleeve S1 is given reciprocating motion by the walking beam W1, which is actuated through a combined effort of the eccentric E1 on the crankshaft and the eccentric E2 on the halftime eccentric shaft. The water-jacketing of the motor has been done with care, and the general design shows the earmarks of a motor engineer.

Knight Makes Modification of His Main Type of Motor

In *Der Motorwagen* of November 30, 1910, there was a description of the modified forms of sleeves as shown in Fig. S at A and B. Referring to A, the junk ring J1 aided by the three rings above are placed to maintain the tight relation of the long sleeve S1. The short sleeve S2 is so fashioned as to press against the outer wall in the cylinder head above the ports and a packing ring P1 is placed in the enlarged diameter of the ring to prevent the leakage of compression. In B, Fig. F, the outer ring is in the down position covering the ports.

Showing the Construction of the Howard Motor

In the Howard motor, which is given in sections A and B, Fig. H, the crankshaft, connecting rods and pistons conform to the conventions. The valve mechanism is composed of horseshoe-like members a and b in the head above the piston on the top of the stroke, with slots S1 and S2, which are covered and uncovered according to the four-cycle principle, and a reciprocating motion that is required for the purpose is imparted to the covers by means of the rods R1 and R2, as shown in the section B.

Referring to the section A through the cylinder and valve covers, the cover a is over the port P1, but the cover d is in the position of "open," permitting the flow of gas from the port P2. A further examination of this type of valve mechanism places it in the class with the Reno motor, and the sliding members forming the valves are held to their seats by pressure.

Referring to the Redrup Type of Sleeve Motor

Fig. I is a section through a cylinder of the Redrup type of sleeve motor showing a single sleeve between the piston and the bore of the cylinder, the main difference being that the sleeve is in two halves H1 and H2, split through the diameter as indicated by the line a, and the two halves of the sleeve are given reciprocating motion to cover and uncover the ports in the four-cycle timing relation. In the patent specifications of this motor the sleeve members are described as follows: "Consisting of a tapered sleeve split in halves lengthwise and fitted inside a cylinder which has one end closed to form the combustion chamber. The slides are at the inner end of their travel (as shown) so as to cover the ports B1 and B2; the slides would remain in this position during the compression and power stroke of the piston P3, which reciprocates within the parallel bore of the sleeves H1 and H2. Owing to the outside of the sleeves and the inside of the cylinder being slightly tapered, when the slides are in the position shown, pressure will be exerted on their meeting faces along two diametrically opposite division lines, thus making these two joints tight, and also making a tight joint by each sleeve over the two ports, and also between the sides of the slides and the piston. The inner ends of the slides are their thin ends, and the outer ends are the thick ends, while the bore of the cylinder is smaller at the inner end and larger at the outer end." The invention provides for the linking up of the slides in any suitable way.

O. Mustard Comes Out with a Modification of the Idea Described in Fig. J

During the last Paris Salon interest was taken in the design of motor as shown in Fig. J, which is a section through the same, presenting a sleeve S1 in the bore of the cylinder accommodating the piston, the sleeve being in two halves a and b, split longitudinally. Motion is imparted independently to the respective halves of the sleeve to give the four-cycle timing. This sleeve motion is induced by cams C1 and C2 on opposite sides of the crankshaft and is interpreted by rollers R1 and R2 through a bell crank B1 and B2, thence to linkages L1 and L2. The camshafts are in the halftime relation with the crankshaft.

W. W. Moore Resorts to the Use of a Single Sleeve

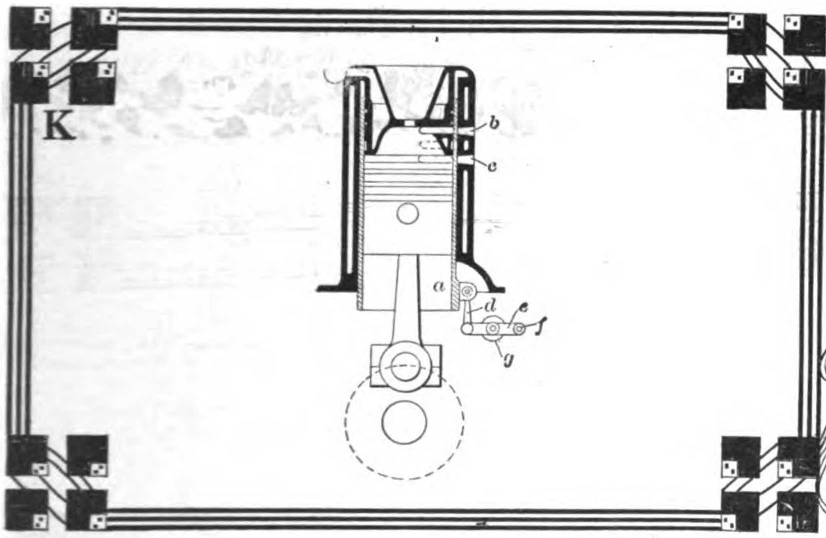
Referring to Fig. K, showing a cross-section of a cylinder of a motor, the single sleeve A is in the concentric relation with the piston in the bore of the cylinder, and the ports b and c are uncovered according to the four-cycle principle of timing, reciprocating motion being given to the sleeve through the links d interpreted by the lever e with a fulcrum at f and a cam motion g. In other respects this type of motor conforms to the main idea of sleeve design.

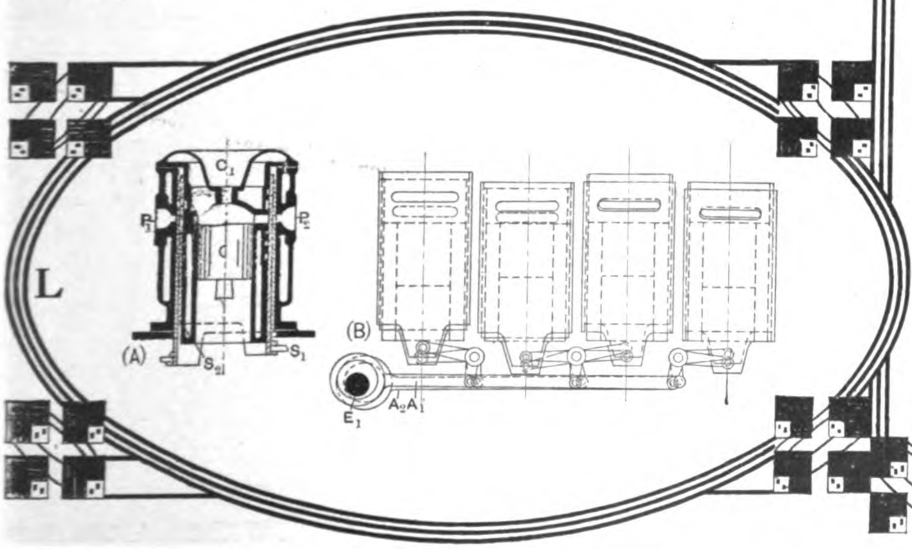
Chalmers Takes Kindly to the Two-Sleeve Idea

Fig. Q presents a Chalmers motor of the double-sleeve type in part section, the sleeves being of different lengths with a long sleeve L1 within and a short sleeve S1 between the long sleeve and the bore of the cylinder B1. Motion is imparted to the sleeves through the link L2 for the long sleeve, and the link L3 for the short sleeve from an eccentric E1, taking rotary motion from the crankshaft S2, the speed of the eccentric being half of the speed of the crankshaft. A is the inlet port and B2 is the exhaust port. The invention has been described as consisting in supplying air under pressure for scavenging and adding to the inlet charge. The air is admitted into the crank chamber by the passage C1 and compressed on the down stroke of the piston. The compressed air then finds its way by the passage D1 through the port E2 which at the right time registers with the port F1. In this way the air compressed in the crank chamber is allowed to enter the cylinder twice during each cycle. This occurs at the end of the suction stroke after the inlet valve is closed. Thus the gas in the cylinder is added to by the amount of compressed charge supplied, and to compensate for the dilution the gas taken through the inlet port A is richer than usual. On the exhaust stroke fresh air is again admitted under pressure. In this case it affects the scavenging action.

D'Orsay McCall White Type of Motor

This motor is of the double-sleeve type, but instead of placing the sleeves within the bore of the cylinder in the concentric relation with the piston, they are placed between the outer wall of the water jacket and a protecting exterior sheath. The sleeve S1 is given reciprocating motion through the connecting rod C1, assisted by a guide G1, and the sleeve S2





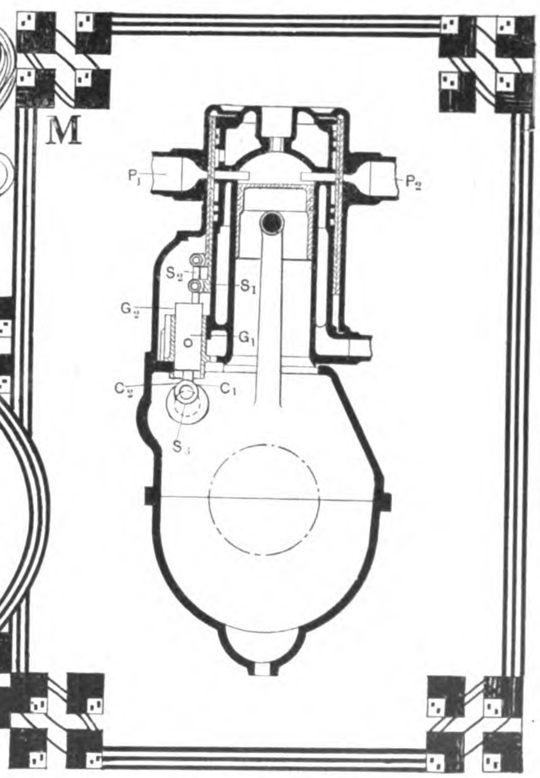


Fig. K—Section of Moore motor, using single sleeve, with slots one above the other
Fig. L—A, sectional view of the Riley sleeve motor. B, valve operating mechanism of the motor showing the relation of the ports in the sleeves

Fig. M—Section of the D'Orsay McCall White Motor, showing the stationary valve guide situated inside and endwise-movable tubular distribution valve is reciprocated by the connecting rod C2 through a companion guide G2. The connecting rods have motion imparted to them by eccentrics on the shaft S3. This shaft is driven through a train of gears by the crankshaft in the usual way. Gas is admitted through the port P1 and exhaust is out of the port P2. The slots in the sleeves register in a manner conforming to the four-cycle relations and leakage by the sleeves is prevented by rings in grooves suitably disposed in the exterior walls of the water jacket, assuring tightness under all conditions.

Lanchester Motor of the Two-Sleeve Type

Referring to Fig. N. of the Lanchester motor with two sleeves S1 adjacent to the piston in the concentric relation and S2 between S1 and the cylinder C1. The mode of operation imparting reciprocating motion to the sleeves is through a connecting rod C2 for the inner sleeve and another connecting rod C3 for the outer sleeve.

Reciprocating motion is imparted to the inner sleeve S1 through the connecting rod C2 by the eccentric E1 on the shaft S3, and motion is imparted to the sleeve S2 through the connecting rod C3 by the eccentric E2 on the shaft S4. The ports P1 and P2 are covered and uncovered according to the four-stroke cycle principle. The cylinder head H1 is water jacketed and it is inserted into the bore of the cylinder which terminates in a spherical dome.

The shaft S4 by which the outer sleeve is driven, is mounted coaxialy with the cylinder container, or may be arranged independently, so that the position of the shaft and the motion of the outer sleeve are unaffected by movements of the lever L1. The shaft S3 on the other hand receives motion of two kinds when the lever L2 is operated; it is displaced bodily parallel to itself in such a manner that the duration of the period during which the inner sleeve ports are uncovered with respect to the cylinder head is varied, the timing of mean position of the dead center being substantially unaffected by this component of the motion, but it receives a rotary motion due to the epicyclic action of the gears whereby the timing of mean position of the sleeve is also caused to vary.

McIntosh Sleeve Type of Motor Has an Overhead Mechanism

Referring to Figs. O and P of sections through one of the cylinders in two planes, the sleeves are given reciprocating motion from an eccentric shaft E1 mounted on the top of the cylinder through links L1 for the sleeve S1 and L2 for the sleeve S2. According to British patent specifications 28,061, this motor is of the four-cycle type with the two reciprocating cylindrical valve-sleeves arranged concentrically with the working cylinder. Power is transmitted to the operating mechanism from the main shaft through an enclosed skew and a vertical spindle to a lay or second shaft situated along the center of the cylinder head. The arrangement of the cranks, and valve-ports, upon the sleeves, and the movements of the sleeves, for the opening and closing of the valve-ports, is stated to be similar to present practice in the Knight type of motor. The shaft E1 carries upon it at a position at each end of each cylinder a pair of these cranks or eccentrics from which power is transmitted to the valve-sleeves.

Riley Imparts Motion to the Sleeves in an Ingenious Way

Referring to Fig. L, the section (A) through a cylinder of a motor shows the pair of sleeves S1 and S2 within the bore of the cylinder in the concentric relation with the piston with an inserted cylinder

Fig. U—Another example of the Kitchen motor in which an outer sleeve is interposed between the rotary sleeve and the cylinder wall in order to regulate the admission and exhaust

Fig. V—A, sectional view of a further example of the Kitchen motor in which two sleeves of the rotary type are driven by worm gearing. B shows the relation of the water jacketed cylinder to the two sleeves

Fig. W—Sectional view of the Sears reciprocating sleeve valve motor, the sleeve being operated by an overhead eccentric shaft; in this type two pistons are used in each cylinder

head C1 and inlet and exhause ports P1 and P2 as in the Knight motor, and the sketch (B) shows the four pairs of sleeves for an equal number of cylinders operated from an eccentric shaft E1 placed slightly in advance of the front cylinder of the motor, imparting motion to arms A1 and A2 lying parallel to each other in the plane of the crankshaft, the diameter of the cylinder apart and bell cranks, connecting these arms to the sleeves in the respective cylinders of the motor, imparting motion thereto.

Carroll & Ripley Use a Single Rotating Sleeve

In Fig. R showing the elevation of a motor in part section, and a single sleeve S1, concentric with the piston P1 in the cylinder C1, with an inserted head H1, with means for water cooling, the sleeve S1 is rotated taking power from the crankshaft C2 through the bevel gear set G1 to the spur gear G2, meshing with a gear G3 on the lower extremity of the rotating sleeve. As the sleeve rotates it covers and uncovers suitably contrived ports according to the four-cycle principle.

The sleeve of the adjacent cylinder is also fitted with a toothed ring which meshes with the tooth ring G3 and in this manner takes motion therefrom. The small section of the cylinder head shows the sleeve as it is related to a post when either on the intake or exhaust stroke. The sleeve extends throughout the whole length of the cylinder, its port opening being sealed during compression and explosion by means of a semi-ring which is located in a corresponding recess, formed in the periphery of the head and a flat spring placed between the inner face of the semi-ring and the bottom of the recess. Packing rings are located in the head as a security against leakage.

Callow & Humphrey Employ a Rotating Single Sleeve

In Fig. S showing a cylinder of a motor in section, the sleeve S1, in the cylinder C1 is concentric with the piston P1, and the sleeve is rotated from the crankshaft C2 through a halftime gearset G1 and a bevel gearset B1 with one of the bevel gears flanged to the lower extremity of the sleeve S1. The sleeve is provided with packing rings at the approach of both extremities protecting ports against leakage, controlling the inlet and exhaust flow to these ports in the cylinder walls. The section (B) through a pair of cylinders shows the horizontal section. The port E in the sleeve is slightly larger than the port J in the packing ring, so that the pressure in the cylinder during compression and explosion stroke acts upon the exposed parts of the packing ring and secures good contact between it and the cylinder wall. At other points in the sleeve apertures D and D1 are provided for the purpose of increasing this effect. A gas admission chamber A1 and expansion chamber K1 are provided in communication with the inlet and exhaust ports of the cylinder respectively. Near the lower end of the sleeve S1 in Fig. S a collar C2 rests in a bearing N in the cylinder base plate.

J. G. A. Kitchen Contributes a Quota of Sleeves

Fig. T gives sections A and B of a rotating sleeve type of motor and referring to section A the sleeve S1 between the piston P1 and the cylinder C1 is given rotation by the worm W1 and the worm wheel W2, the latter being on the bottom end of the sleeve within the cylinder and the rotation of the sleeve covers and uncovers the inlet exhaust port successively according to the four-cycle principle.

Kitchen also worked upon a design of a sleeve type of motor as shown in Fig.

U which is given in sections C and D. The inner sleeve S_1 is operated by a worm W_1 in mesh with a worm wheel W_2 in the same manner as the rotation of the sleeve in the cylinder as shown in Fig. T. The two sleeves in Fig. U are concentric with the piston P_1 of the cylinder C_1. The outer sleeve in this motor is actuated by the lever L_1 through a controlling mechanism, and the ports in the outer sleeve are so arranged as to control the incoming mixture.

Kitchen has also worked upon the double sleeve type of motor as shown in Fig. V showing a section through the cylinder at A and a section across the cylinder at B. In this motor the inner sleeve S_1 is rotated by means of the worm W_1 meshing with the wheel W_2, and the outer sleeve S_2 is given rotation by the worm W_3 meshing with the wheel W_4. The section B shows the relation of the ports in the sleeves, they being covered and uncovered, due to the rotation of the sleeves and the relation that exists between them.

I. E. Sears Operates a Pair of Sleeves from the Top

Referring to Fig. W showing a section through the Sears motor, and the sleeve S_1 concentric with the pistons P_1 and P_{11} in the cylinder C_1, covering and uncovering ports P_2 and P_3. Reciprocating motion is imparted to the sleeve through the eccentric shaft S_1 by means of the connecting rod C_2 for the auxiliary piston, and the connecting rod C_3 for the sleeve. The sleeve is shown with the ports covered, and the operation of the motor conforms to the four-cycle principle. This motor differs from all of the other types illustrated to the extent that an auxiliary piston works in conjunction with the main piston in the cylinder.

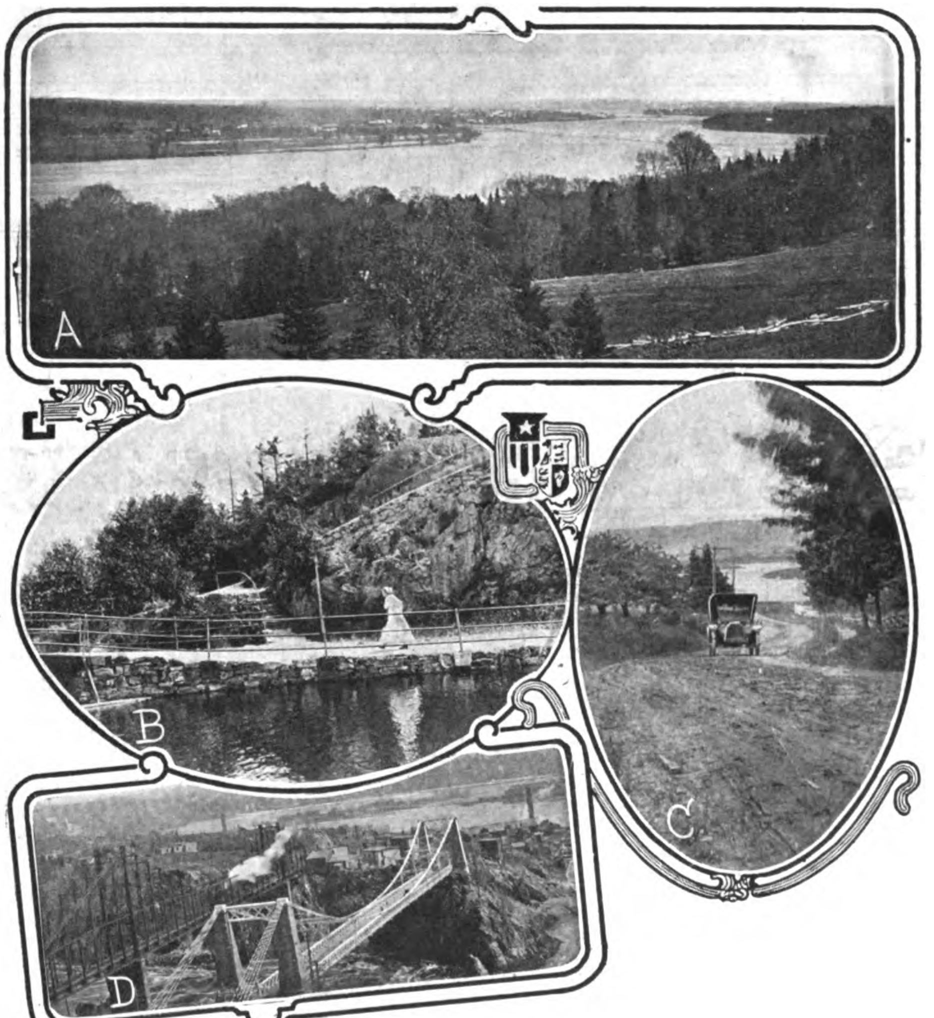
THE KAISER'S MOTOR CAR "FLEET."—Emperor William of Germany has just purchased four more new types of automobiles, thus augmenting his motor car fleet to thirty and again emphasizing his stand as an enthusiastic motorist. The majority of his machines are of German and French make. Six of these cars are utilized as luggage vans. The Kaiser keeps five of his automobiles at Corfu. No other person is permitted to possess a horn like that used on His Majesty's motorcars, the type of horn being that of a peculiar fanfare. When in commission the car bears the Imperial Standard flag, which flies beside the chauffeur by day. This ensign is replaced at night by an illuminated glass shield, revealing the Standard in regulation colors.

NEW FRENCH TRUCK BECOMING POPULAR.—France has just introduced a new type of motor truck. It is equipped with a tilting platform, about thirteen feet in length, and a capstan. The truck has a capacity for carrying loads of great weight, which, by reason of platform and capstan, are handled both in the loading and unloading at a wonderful saving of hand labor. The platform is tilted over the rear axle, while the leading truck is run out upon the ground. After having loaded the goods upon the truck, the workmen draw the truck back upon the tilting frame by means of the capstan. The frame is then tilted back and locked in its place. Not only have manufacturing concerns and commercial houses adopted the truck, but the military authorities have put it into commission.

Motoring in

Touring in the

Some information as to the best routes to follow in taking an fellow's masterpiece, with pertinent data, reinforced by a routes, by land and sea, by which the motorist may reach



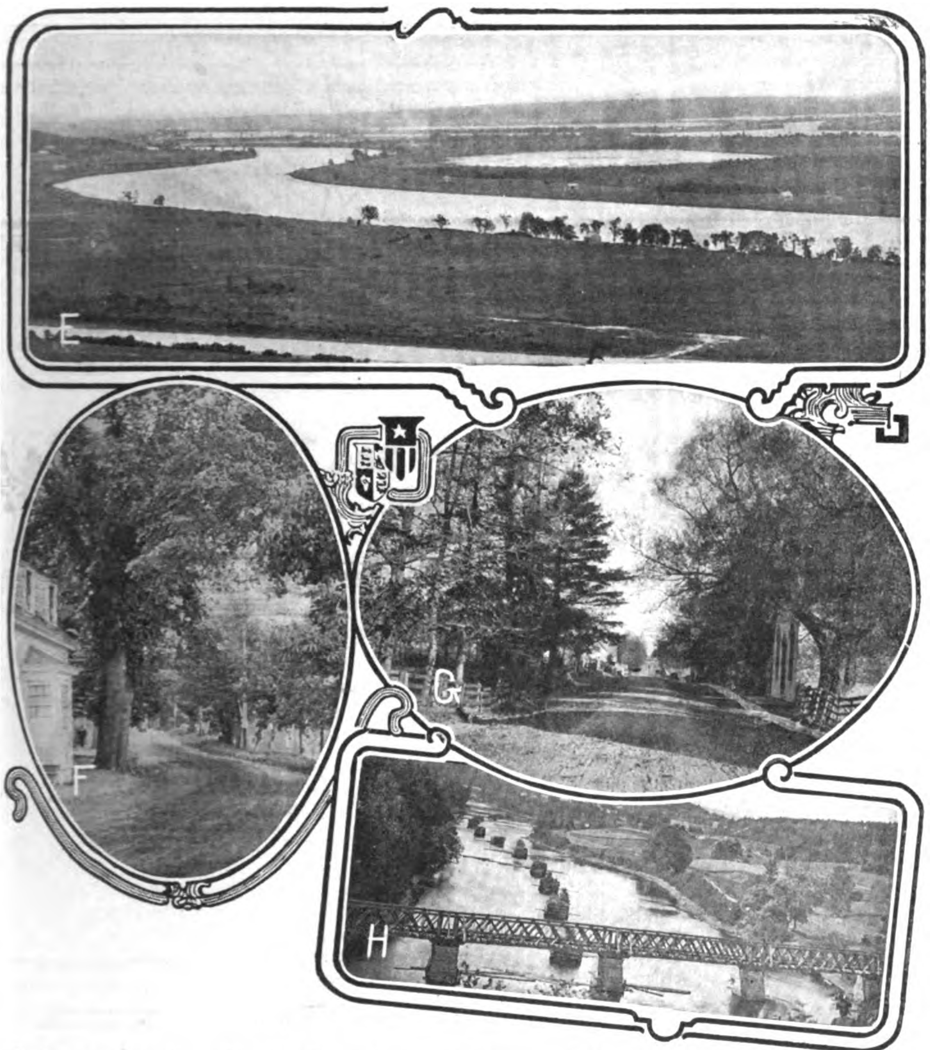
A—An upper reach of the St. John River, taken from the University at Fredericton
B—Spillway at the outlet of Lily Lake, in Rockwood Park, St. John
C—Picturesque road leading up out of Grand Pré
D—Reversing falls at St. John, N. B., showing bridges, river and factories

ONE of the most needful adjurations to give the automobile tourist who would venture into the Maritime Provinces of Canada is "Keep to the left." Nor should the frisky driver forget that he must not trust the occasional level stretches of gravel road, which invariably terminate with an atrocious culvert, calculated to put the stoutest spring out of business. A car recently came from Fredericton with both front springs broken straight through the middle, as if cut with a knife. Then there are the hidden sharp turns at the bottom of steep pitches and on high, narrow embankments which one would do well to watch for. The most flagitious of these medieval road tortures are the stones which stick up in the road as if to test the toughness of the outer casing. At intervals in the early part of the season one encounters those patent road de-

Modern Acadia

Land of Evangeline

automobile tour through the territory made famous in Long-map and excellent illustrations, showing the most comfortable Nova Scotia from New England. By Henry MacNair.



E—Stretch of the lower St. John River, showing the character of the country
F—The tourist, on entering Digby, is impressed by its quaintness
G—Type of road to be found frequently; this one is at Gagetown, N. B.
H—Peniac Bridge across the Nashwaak River, near Marysville, N. B.

stroyers which scrape the mud, filth and vegetation out of the gutters into the middle of the road, rendering it all but impassable until the friendly showers wash it all back again. After plowing through some of the road which has been "fixed" one occasionally comes upon a modern road drag which is doing sane and satisfactory work at a minimum expense, and no other argument is necessary to convince one of the superiority of the road drag over the road scraper than to travel over two adjacent sections worked by these machines respectively.

Having decided to be content with an average of twelve miles per hour and to forget the bumps in the wonderful historic and scenic interest of this country, the tourist will find a trip to Acadia an experience which he will never forget. The accompanying map shows the principal touring routes in this section with a connection from New York along the shore of New England, directions for which are shown in detail in Volume 2 of the Automobile Blue Book. Or one may ship his car to St. John or to Yarmouth, taking up the trip at either of these places. Perhaps the most satisfactory overland route to St. John is via Bangor, Bolton and Fredericton. From St. John two very interesting round trips offer themselves, the first being from St. John to Moncton, Truro, Halifax and Digby, returning to St. John by steamer or going on to Yarmouth and returning to Boston by steamer. The second, going from St. John to Fredericton, then across the heart of New Brunswick to Chatham, returning to St. John via Moncton. Another plan would be to drive from St. John to Edmundston, ship the car to Campbellton and then along the beautiful shore of Baie de Chaleurs and the Northumberland Strait to Moncton! then to Halifax and Yarmouth, returning to Boston by steamer. All of these roads are passable, and there are no unsurmountable difficulties, but the driving should be done with extreme caution and no great speed attempted. The tourist entering this part of Canada will find it necessary at the port of entry to arrange for a bond covering the amount of customs on the machine, which is 35 per cent. of the valuation. He must then secure a driver's license and register his car under the laws of Canada before proceeding.

The first impression of St. John is that of a very dull and dingy seaport, although it is picturesquely situated at the mouth of the St. John River and is historically interesting from the fact that Champlain and De Monts visited the harbor on the day of St. John the Baptist, June 24, 1604. The first European settlement, however, was made in 1631 by Charles de la Tour, who built a fort on St. John harbor. It would be interesting to follow the varying fortunes of La Tour and his successors as Acadia passed in turn from the British to the French and from the French back to the British. The real existence of St. John did not begin until after the landing of the United Empire Loyalists in 1783. These came from the neighboring United States, not desiring to unite their fortunes with the young American nation.

Among the various points of interest about St. John are Market Slip, the landing place of the Loyalists, where still stands a town bell used for calling workmen to labor and from labor to refreshment. Perhaps the best known natural feature is the reversing falls of the river St. John, where the river makes its way through a channel 450 ft. wide between tall cliffs of limestone. Here the tide rushing outward through the narrow channel gives one the impression of rapids or falls, whereas the incoming tide which here rises to about 25 ft. rushes in and reverses the condition. The favorite and most picturesque drive out of St. John is up the valley of the beautiful Kennebecasis, which extends for about 50 miles to the northeast. This road is the one to be taken to Moncton. Passing out of the Kennebecasis Valley, the tourist ascends a ridge from the top of which there is a fine view looking back. Then comes a descent into the valley of the Petitcodiac River, whose wet clay slopes at low tide give one the impression of a recent freshet. Moncton was named for an English general and is best known for the tidal bore which comes up the Petitcodiac River twice daily. This wave comes in at the beginning of the inflowing tide and sometimes reaches a height of eight feet. The drive from Moncton to Truro down the isthmus is picturesque in spots, but unless the coast road is taken through Parrsboro one is very likely to find rough going.

One of the most interesting parts of the trip to Halifax is along the chain of lakes which begin south of Shubenacadie. Halifax might be called the Ultima Thule for American automobile travel, for beyond it one cannot go. The city itself boasts of several good hotels and is by far the most interesting and picturesque city of the two Provinces. Its most conspicuous feature is the Citadel, which occupies a commanding position at the topmost elevation of the small peninsula upon which Halifax is located. This hill was fortified in 1778, but the present fortress was begun in 1794. From the Citadel an unexcelled view of the city harbor may be had.

The drive from Halifax to Windsor, a most interesting one, follows the shore of the harbor to Bedford, when it ascends Mt. Uniacke on a very rough and stony stretch. At Windsor is the head of the Basin of Minas, made immortal by Longfellow in his "Evangeline." Shortly beyond the road leads through Grand Pré, the scene of the principal happenings so vividly outlined in that wonderful drama-poem. Leaving the Basin of Minas, the road leads over a low bridge and descends into the Annapolis Valley, whose beauty and charm have often been sung.

At Annapolis Royal is an old fort dating from 1660 and a monument to Sieur de Monts. Digby is a picturesque little village at the mouth of the Annapolis River, which passes into the Bay of Fundy through Digby Gut. Steamers ply between this point and St. John, and if one is tired of the trip the boat may be taken across the bay, or the trip may be continued to Yarmouth, where there are excellent hotel accommodations and steamer connections to Boston.

Of the other interesting automobile trips to the Provinces the most popular is from St. John to Fredericton, either by the river road or the back road, the river road being the most in favor on account of the beautiful views of the St. John. From Fredericton the tourist should follow the valley of the Nashwaak River and descend into the valley of the Miramichi, known as the fishing grounds of Canada. From Chatham an indifferent road runs across the marshes through several small villages into Moncton, and the return trip is made to St. John through the Valleys of the Petticodiac and Kennebecassis Rivers.

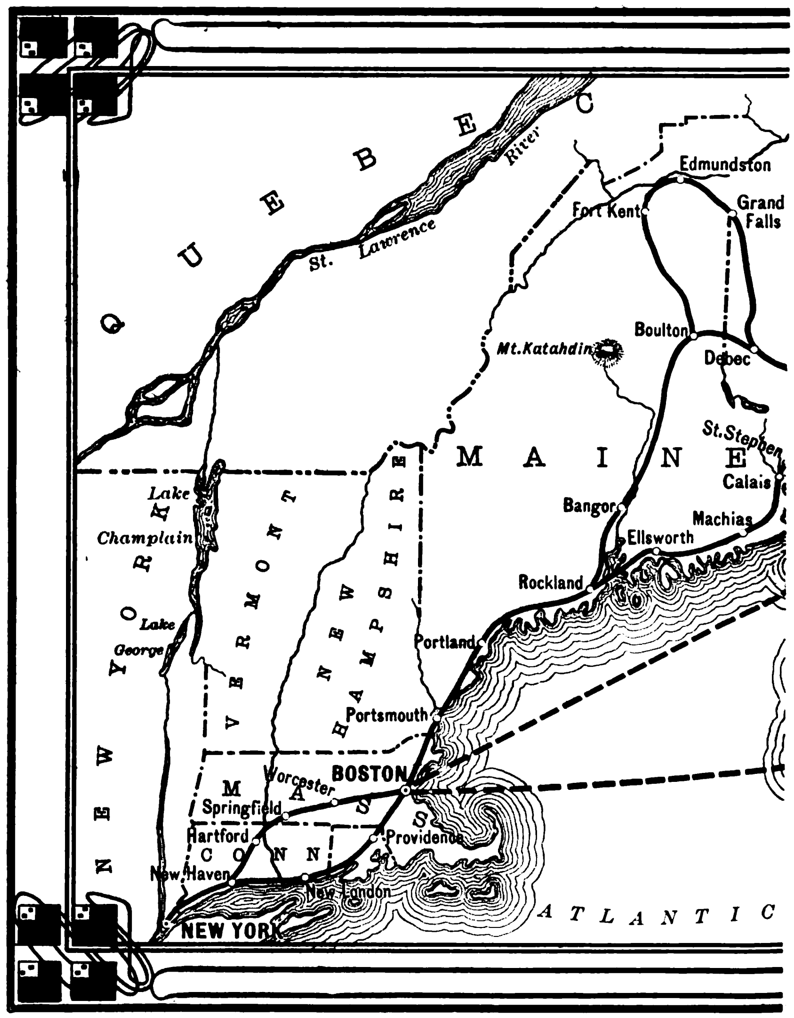
In Further Relation to Lubricating Problems

Charles E. Duryea presents additional argument in support of putting the lubricating oil into the gasoline and supplying these products to the motor in mixed form on the ground of simplicity.

I AM unable to get away from the feeling that you, for some reason, are opposed to accepting a good method of oiling. I am unable to find anything in your argument that is really against the mixture method as proposed by me. That there is, as an inadvertence, some mixing of the oil with the new charge in the crankcases of every two-cycle engine goes without saying. But what of it? The mixture method of feeding oil into a two-cycle crankcase, according to my view, is not an inadvertence. I look upon it as a well-planned and accurately operating method, which is superior to other methods. You might say that it was an inadvertence when Columbus discovered America, but he worked under an up-to-date plan and deserves credit acaccordingly.

Your play on words in your endeavor to show that the mixture method of feeding oil is a complex method, in my judgment, is unworthy of you. I venture to assert that none of your readers have been confused by the terms employed. They know that when we speak of the virtues of simplicity we do not refer to a type of machine which is lacking in some vital part, whereas we do have in mind the type of machine that has the minimum number of parts and is capable of performing a given service. The mixture method of lubrication dispenses with the oiling machinery as far as the engine lubrication is concerned, substituting a method which I consider more nearly correct in action and more certain to deliver the desired results. This, I take it, is the kind of simplicity that the user wants.

That the mixture method of oiling is mostly applied to two-cycle engines is no argument against it. One four-cycle engine that I know of is built that way, and I have no doubt that others will be so made. Practically every engine nowadays is built with a tight crankcase to keep out the dirt. Just why a mixture may not be carried into the tight case and



Map showing the geographical relations of the New England States to Nova Scotia, (Courtesy of the Official

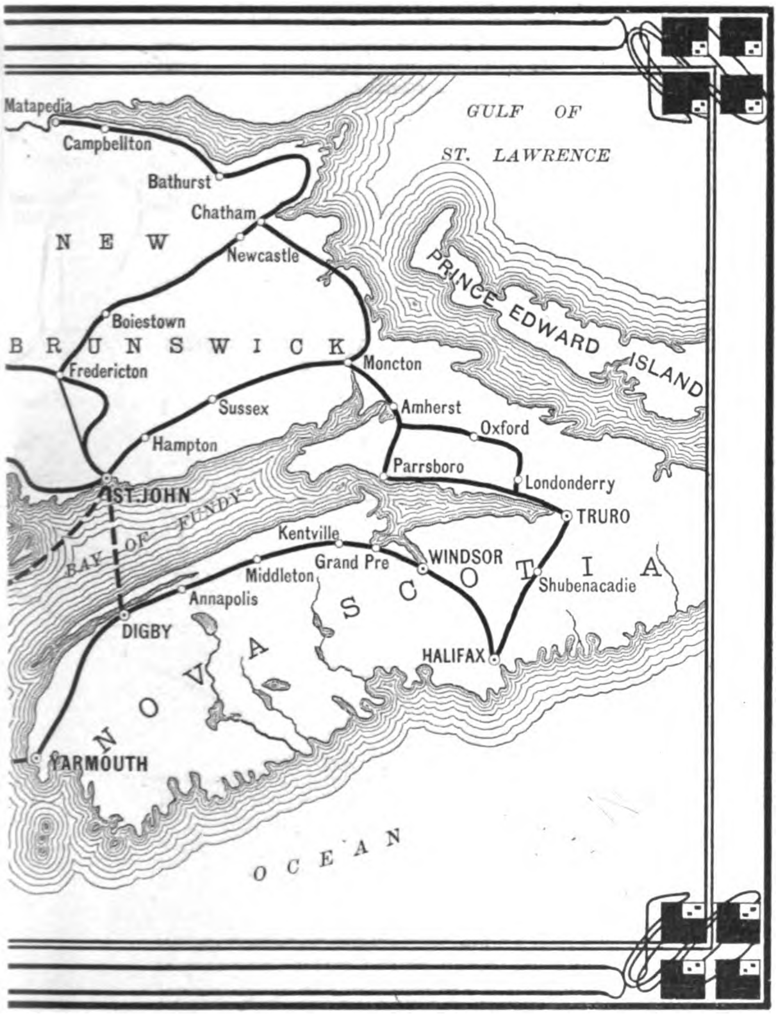
out again, as is done by Holsman, I do not see. It is very possible that engine makers have something to learn yet. It is certain that such a method would render needless some of the parts now considered necessary, and this is the thought that every up-to-date engineer keeps in mind and works for. The engineer knows that needless parts add needless cost in the first place, may offer trouble in the second place, must be kept in repair in the third place, and eventually replaced in the fourth place, not to mention the weight that the presence of these devices would necessarily add, nor forgetting the power that they absorb. I trust that these discussions will at least make designers think.

In the absence of a means for regulating discussion, the germ of irrelevancy creeps in with great persistence, and argument is prone to browse around over a 40-acre lot, making it substantially impossible to adhere to the original subject and to arrive at some conclusions.

The first principle of efficient lubrication is founded on the idea of an unbroken film. The only way that an unbroken film can be assured, referring to the film of lubricant between the journal and the bearing, is to employ a suitable grade of lubricating oil and to be sure that it is not adulterated. As to the question of adulteration, it is not difficult to reach the conclusion that lubricating oil with gasoline in it is adulterated, nor does it matter whether the gasoline is put in it on purpose or otherwise.

Granting that Columbus discovered America, it is not without contending that the good Queen Isabella furnished the lubricant up to an unadulterated standard, and she must have appreciated how necessary it was to avoid adulteration, since there are those who suspect that she put her jewels in pawn to get the gold (lubricant) that Columbus used as the price of his outfit. In the Holsman motor, which is used as an example for designers to go by, it still remains to say that the plan was in the nature of an inadvertence, in view of the fact that Holsman would have had great difficulty in doing the work in any other way but the one as chosen by him. It is no argument to state that a thing is better if it is done in a certain way, if it is a fact that the doer of the job has none but a Hobson's choice.

We are struck by the funny way that users have of showing their high appreciation of simplicity, for, as Mr. Duryea states, "this is the kind of simplicity that the user wants." Statistics would seem to indicate that the users of automobiles are so taken with the mixture idea that 99.9 per cent. of them invest their money in something else.



with the best routes to and from the Land of Evangeline, both by land and water Automobile Blue Book)

Hot Weather Tip

Those who use the ordinary type of bulb operated horn may find that during the hot weather the bulb, which is usually made of rubber, becomes very sticky. This can be overcome if a small bag is made out of a piece of linen and sewn over the bulb. A more permanent fitting can be made of leather and attached by a lacing.

Government Motor Car Service in East Africa—From the East African Protectorate word comes that a plan is being worked out whereby motor car service is to be established by the Government for the accommodation of the postoffice, and likewise for landowners who raise perishable produce. The highways have been improved and the outlook for automobiles in this section is bright.

It Stands to Reason—

That you cannot discriminate against the motor in your automobile without being paid in coin of the same realm.

That discontent is catching; if you invest in a discontented automobile you will experience discontent within a week.

That a good automobile should not be disassociated from a kindly disposed owner.

That a dramatic critic of some power might have a lot to say about an intoxicated driver.

That the owner of an automobile should deprive the dramatic critic of his opportunity.

That subjects for discussion should not include deflated tires in service.

That a straightforward type of motor in a car is entitled to frank and fair treatment.

That a drone in the chauffeur's seat makes an active repairman in the shop.

That drudgery is a condition that rests under the shadow of previous neglect.

That a chauffeur arrayed in an alcoholic mind is an economic blunder.

That chauffeurs are too often the victims of a bad example.

That a long stop at a road house is the first indication of a wrecked automobile.

That "sand" is more appropriate in the gizzard of the driver than it is in the gearbox.

That the glamor that is hinged to a coat of red paint on the body is not necessarily the sign of a good automobile.

That the designer who will make a little room for wearing apparel will be on the highway to fame.

That the rattle of tools in a poorly contrived box makes faces at a silent motor.

That a self-binding reaper from the land of trouble has a monkey-wrench in the hands of a "bonehead" as its partner.

That fixing an automobile piecemeal is like handing money to a burglar for safe keeping.

That the path of glory may lead to a grave, but it is a short one for the fellow who drives fast without looking ahead.

That it is better to "get a horse" to rescue an automobile than it is to get an ambulance to succor a reckless driver.

That the shortest distance between two points is not necessarily through a fence into a corn-field.

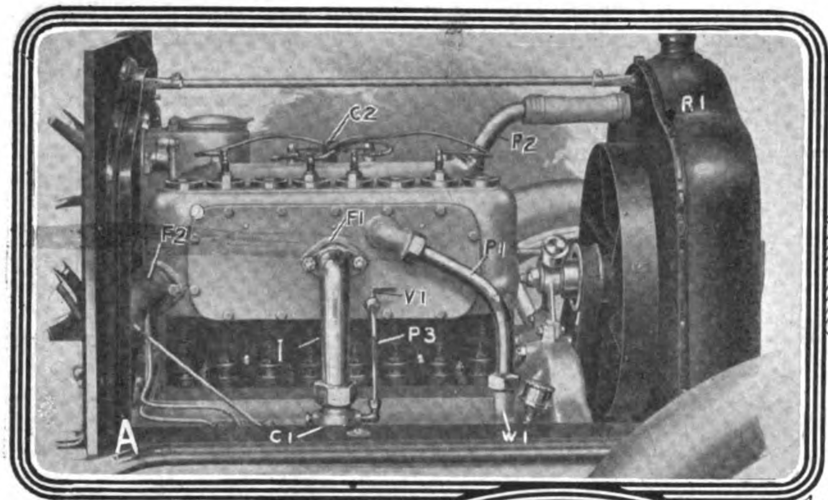
That it is useless to waste sentiment upon a motor—what it needs is lubricating oil.

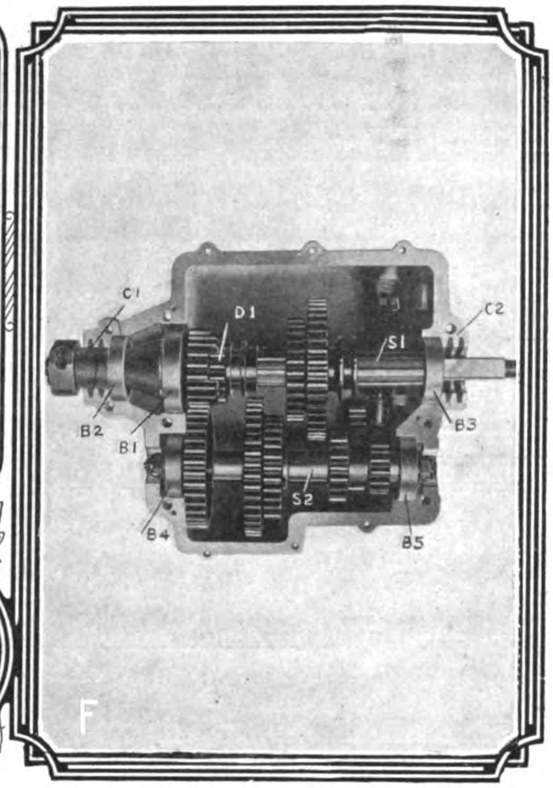
That motors must have an enjoyable time telling each other funny stories when they get back to the garage.

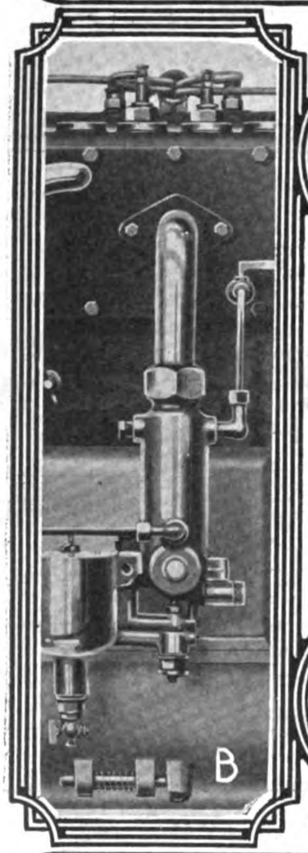
Standardizing Signals

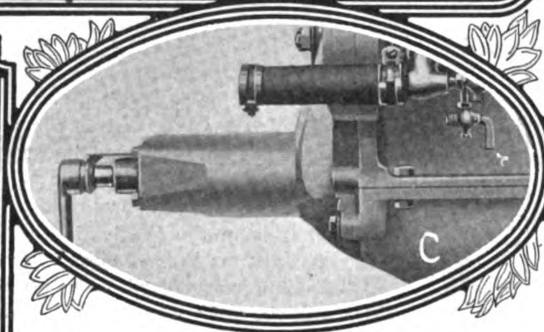
The feasibility of securing the adoption of a law which shall render it obligatory for motorists in the United Kingdom to equip their cars with uniform warning signals has been discussed, it being asserted that the present multiplicity of such devices has a tendency to "rattle" pedestrians.

English law makes it compulsory upon automobilists to "carry a bell or other instrument" on motor cars. To this end the Local Government Board says that the signal "shall be used whenever necessary." This rather indefinite phrase is sometimes hard to interpret, for example, in a case of alleged neglect, when the matter is referred to a Magistrate. But the problem of the motor car horn, "hooter," siren or "road clearer" has become so great and the kinds of "instruments" in use so numerous that both motorists and pedestrians are in a muddle. To get out of it they are considering the feasibility of calling upon the respective Local Government Boards to agree upon some one definite type of horn to be used. Throughout the country English motorists seem to show a liking for a certain type of bugle, which contains ten notes, comprising the diatonic scale of the key of G with F sharp and an extra A added.



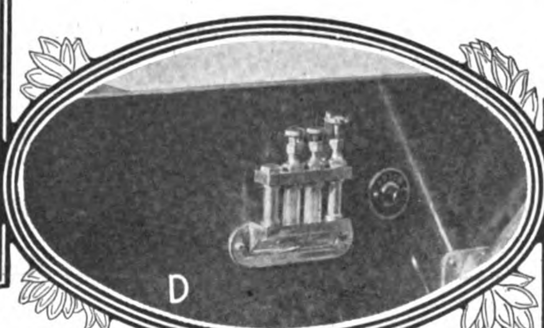


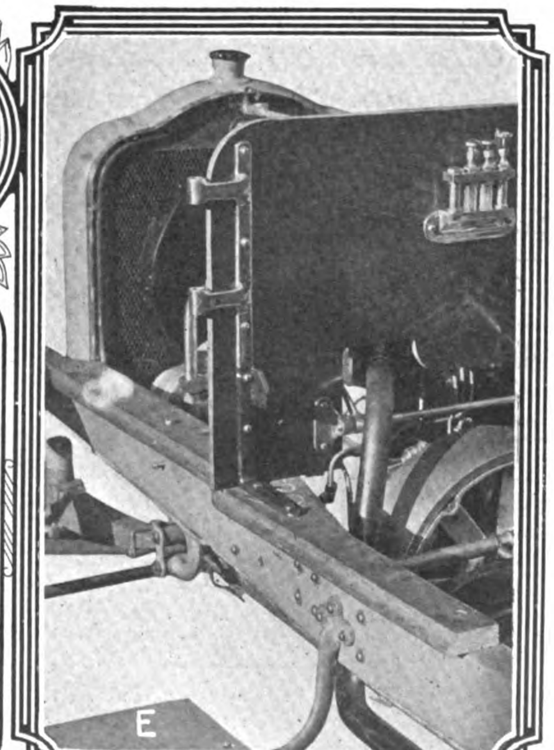


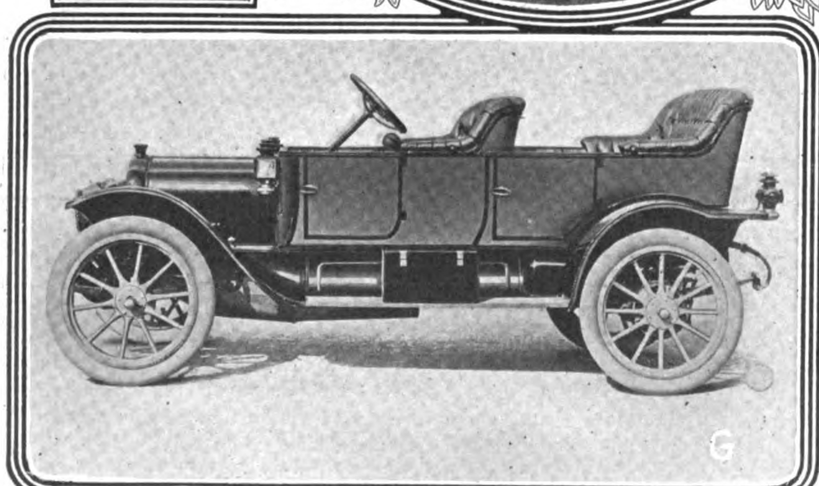


White Company Adds "Six"

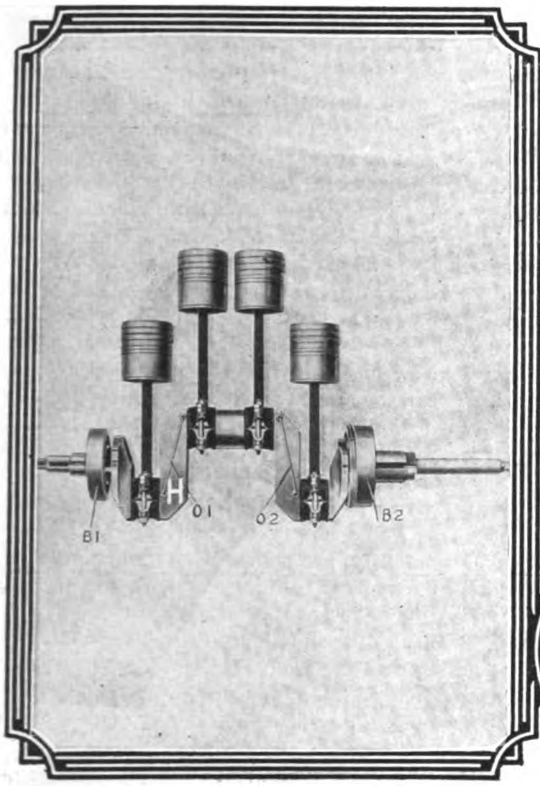
Continues to Make Steamers

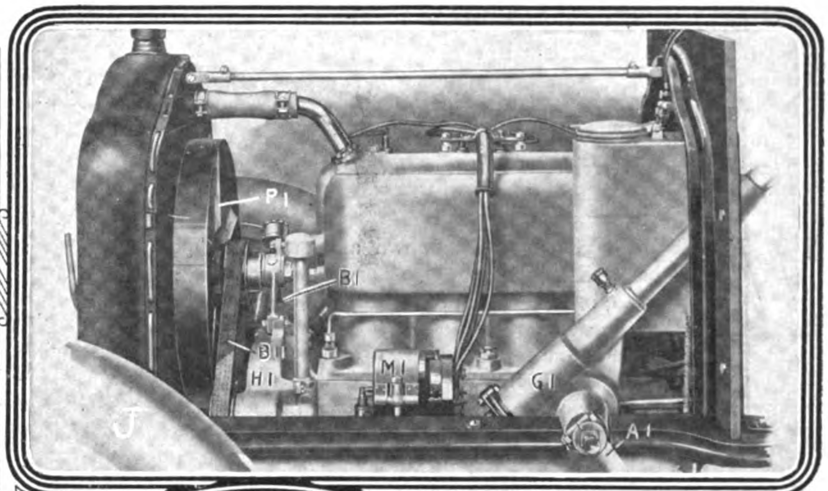


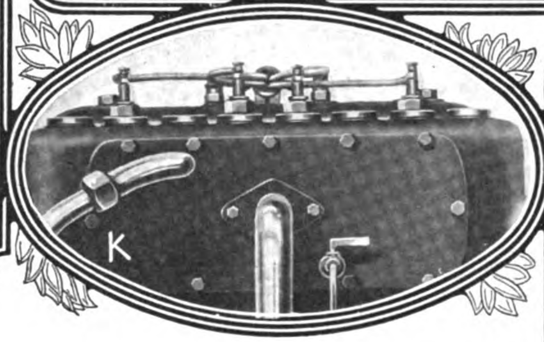


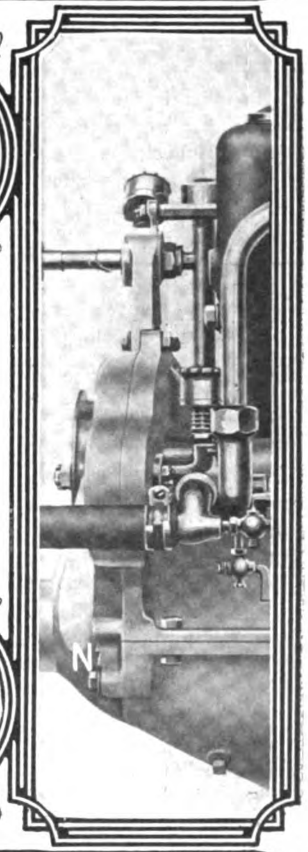


A—Left-hand side of the "GE" White motor with valve cover removed. B—Showing the carbureter of the 30-horsepower White gasoline engine together with hot-water jacketing and valve covers. C—Front end of the motor, showing the extension of the crankcase and starting crank. D—View of the dash of the White "30," showing the switch and sight-feed lubricator. E—Side view of the 1912 fore-door White touring car. F—Gearset of the White 1912 gasoline car, showing the high-speed pinion in mesh. G—Part view of the 1912 White "30" chassis, showing the method of suspending the transmission and the operation of the gear-shift.



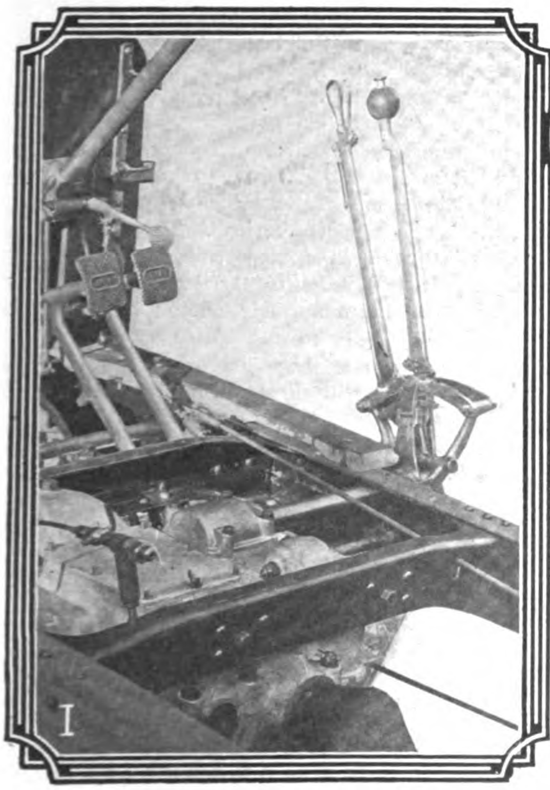


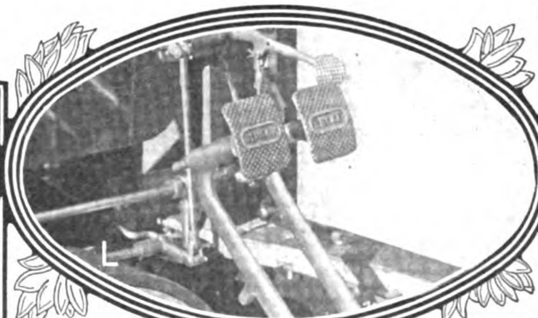


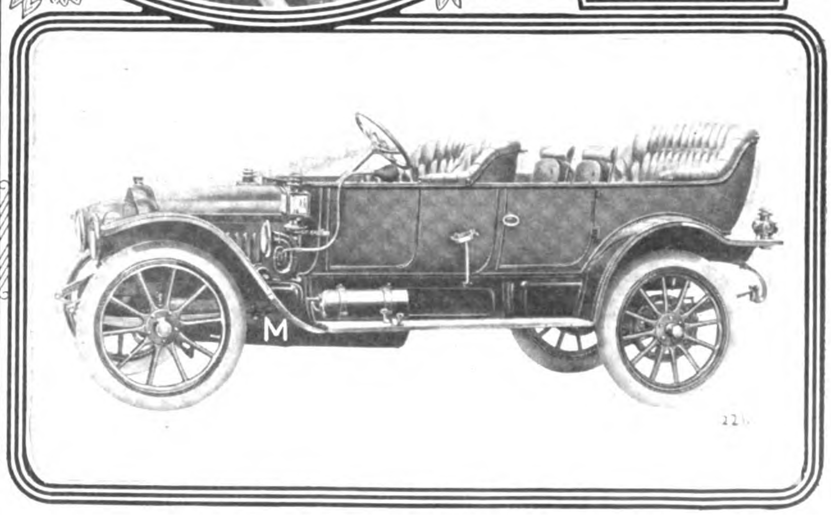


to Gasoline Automobile Line

in Response to the Demand







H—Crankshaft of the White 1912, showing the ball bearing supports and the oil leads. I—Front end view of the White "30" chassis, showing the leather-faced clutch, the broad section of the chassis frame, and the shackling of the front springs. J—Right-hand side of the gasoline "GE" engine, showing the position of the magneto, fan, steering gear and lubricating oil tank. K—Side view of the White gasoline 30-horsepower motor, showing the intake manifold, water connection and spark plug. L—View of the foot control, showing the clutch, brake and accelerator. M—Side view of the seven-passenger White gasoline touring car with left-hand control. N—Side view of the front of the 30-horsepower White motor.

In view of the demand as it is felt by the company for steam as well as gas automobiles, the steam models are continued substantially as heretofore, and the gas models have been revised and brought up to date, adding a "six," according to the illustrations given with this article, and in line with the following discussion.

WITH a six-cylinder to be known as a "60," including suitable revisions of the "30" and "40" models, the White Company, of Cleveland, Ohio, is prepared to meet its clientèle with a view to filling its devious wants, with the same degree of care and precision that has been the underlying principle of the company's activities heretofore. A striking feature of the new six-cylinder model lies in the fact that the six cylinders are cast *en bloc,* thus bringing this new car into the same school of design as that which characterizes the four cylinder models of the same make.

The 1912 line comprises four different chassis under catalogue designations "GB," "GE," "GAD," and "GF." The "GB" model is the 30-horsepower chassis mounting a limousine or a landaulet body. The "GE" is the 40-horsepower chassis mounting five or seven-passenger touring bodies, also limousine, Berline limousine or landaulet bodies. The "GAD" is the 30-horsepower chassis mounting a new touring body, and the "GF" chassis represents the new six-cylinder model. This model is made up with a seven-passenger touring body, or the purchaser may have the option of a landulet, limousine or a Berline limousine.

All bodies, whether for open or closed cars, are built with foredoors. The body list also includes a toy tonneau on the "30" chassis, and a roadster body on the "30" and "40" chassis.

Discussing the Mechanical Features of White Gas Cars

Referring to Fig A, showing the left-hand side of the Model "GE" engine, the carbureter C1 is attached to the upward sweeping intake I1, leading to a flange F1 about midway on the block casting of the cylinders. The water pump W1 delivers water to the cylinders through the pipe P1 circulating the cold water around the inlet and exhaust valves which are on the same side of the motor, and the water passes out at the top through the pipe P2 to the radiator R1 in front, the latter being of the well-known White design, and similar in appearance on gas and steam models of this make of car. The exhaust passes out through the fitting F2 to the exhaust pipe which sweeps down, clearing the flywheel, to a position clear of the chassis frame, back to the muffler, and away to the atmosphere. The high-tension leads come through the conduit C2 to the top of the cylinder casting and are connected to the four spark plugs placed in the covers over the respective inlet valves. The carbureter is provided with a water jacket, and the hot water required for heating the auxiliary air passes down through the pipe P3, a valve V1 being placed in the length of the same, so that the water can be shut off if the occasion requires.

The opposite side of the "GE" motor is presented in Fig J, showing the magneto M1 near the front end of the motor, taking its drive by a shaft terminating in a gear, the latter being in the halftime train and enclosed by a housing H1. On this side of the motor, the steering gear G1 comes into view with the steering arm A1 on the end of a shaft extending out of the steering gear housing above the top of the chassis frame. The air propeller P1 is substantially mounted on a bracket B1, and power is delivered from a shrouded pulley on a shaft extending out through the front end of the halftime box, transmitting the power by means of a belt B11 to the fan pulley. The motor is suspended on the frame at three points, and this method of suspension is also applied to the gearbox. Referring to the details of the cylinder castings, the intake and exhaust passages are integral parts of the castings. It is claimed for this method of casting the cylinders that alignment is assured; moreover, the gases are delivered to the cylinders at a temperature favorable to ready combustion, and the disposal of the burnt gases is facilitated. The length of the crankshaft is minimized under this plan, and the resulting compactness of construction also reacts favorably upon the total weight of the motor.

The White type of transmission gear is shown in Fig. F with a direct drive at D1 and a large annular ball bearing E1 supporting the load at this point, and a second annular ball bearing B2 aiding in the support of this shaft. A double-grooved closure C1 excludes foreign matter from these bearings, and a similar closure C2 excludes foreign matter from the annular type ball bearing B3 which is placed to support the other end of the prime shaft S1 which is splined. The layshaft S2 is supported by annular type ball bearing B4 and B5 and foreign matter is excluded from them by means of covers placed over the ends of the housings. The transmission gear is conspicuous for its clean designing, good relations from the clearance point of view of the torque, and the excellence of the material employed.

The crankshaft as shown in Fig. H is of the two-ball bearing type with annular type ball bearings B1 and B2 near the extremities. Oil tubes C1 and C2 are shown in the lubricating system, and in order to defeat flexure the crankshaft is made with large-section throws and pins of the most approved form of material that is available for this purpose. The connecting rods are of neat design, and the well-fashioned pistons are provided with oil grooves in addition to three piston rings, and a condition of exact balance is established as a part of this undertaking.

The remaining illustrations will suffice to indicate consistency in methods of design and construction of the cars, and indicate how the various problems have been disposed of. Referring to the transmission gear it provides four forward speeds and reverse with direct drive on the third, making the gear changes selectively. The gears are of heat-treated steel. The clutch in the flywheel is of the cone-type and the leather facing is held in place by T-bolts with means for their ready removal if the occasion requires. The driving shaft is fitted with two universal joints, and no telescopic joint is employed. Leather boots are put over all joints to exclude foreign matter. Grease cups are provided at points of vantage. The coupling between the clutch and the gearcase is flexibly arranged, allowing for slight variations in alignment. The machinery equipment is protected from dust by a well-designed sheet-metal pan.

The rear axle is of semi-floating type. In the construction of this axle there are three principal divisions; the gearcase and the right and left axle sleeves. A heavy truss extends from the ends of the axle sleeves engaging a saddle on the under side of the gearcase, helping to support the load. The gears in the axle case are accessible through a large cover on the top of the axle housing. The jackshafts in the axle are of heat-treated steel. The gears are removable without splitting the gearcase.

The front axle is a one-piece drop-forging of the I-section made of .40 carbon steel. A ball thrust is interposed between the steering arm and the axle.

The crankcase is of specification aluminum in two sections. The upper section carries all of the working parts. The lower section is limited in its duty to the exclusion of foreign matter, and the holding of oil. It may be well to say here that the motors are of the long-stroke type. The 30-horsepower motor has a bore of 3 3-4 inches and a stroke of 5 1-8 inches. The 40 horsepower motor has a bore of 4 1-4 inches and a stroke of 5 3-4 inches. The six cylinder 60-horsepower motor has a bore of 4 1-4 inches and a stroke of 5 3-4 inches. Ignition is by high-tension magneto. The mixture is made by a White carbureter of the aspirating type with air valves graduated to supply a correct mixture under varying conditions of speed, the air being heated by means of a water-jacket.

The system of lubrication is a combination of "splash" with a positive feed. There is a direct feet to each of the two main crankshaft bearings. Each connecting rod bearing is also positively lubricated by means of all oilways that are cut through and carried on the crankshaft. These oilways are supplied centrifugally through oiling grooves on the crankshaft. Provision is made to insure an abundant supply of oil to the camshaft bearings.

The halftime gears are properly lubricated and a means for lubricating the water pump and magneto drive are also at hand.

The engine being water-cooled is supplied with the cooling fluid by means of a gear-driven centrifugal pump. A genuine honeycomb radiator is used, in the design of which an effort has been made to take advantage of all four sides of each air cell by providing water upon the adjacent surfaces. The water piping, like the rest of the piping throughout the automobile, is a well-executed piece of work. The side bars of the chassis are of heat-treated steel. Front springs on all models are of the half-elliptic type, and the rear springs on all models are of the three-quarter elliptic type. The steering mechanism is of the worm and sector type with ball-thrust bearings. All parts are of heat-treated steel. The gas and spark may be regulated from the steering wheel or by means of foot levers. The gear-changing and emergency brake levers are arranged at the side of the driver. The clutch and service brakes are operated by pedals. There are two brakes on each rear wheel acting on wide drums of wide diameter. The brakes operated by the pedals are fiber-lined, external constricting type. The emergency brakes, operated by the hand-lever, are internal expanding, metal-to-metal type.

Annular type ball bearings of liberal proportions are universally applied in all models. A compression release is used and operated through a small lever on the frame near the radiator which relieves the compression in the cylinders while the engine is being cranked. The mechanically operated valves are interchangeable. The inlet and exhaust valves are situated on the same side of the cylinders. The valves are made with integral stems, and the type of metal employed has been selected for its ability to resist distortion due to heat. The valve springs and stems, together with the relating mechanism, are set in a valve chamber within the cylinder castings protected thereby but accessible through openings that are covered by means of detachable plates. The camshaft of special heat-treated steel is entirely enclosed within the crankcase.

In the operation of these cars various innovations that count for comfort of the driver have been given a fitting measure of care, as, for illustration, the pedals are adjustable as to length and position, and thought has been given to the location of the steering wheel with respect to the seat and accessibility of the levers for purposes of control. The peace-of-mind of the driver is assured through the good office of a well-contrived lubricating system, the ease with which lubricating oil may be added at will, and the facilities for telling the driver how much of the lubricating oil remains, and the distribution of grease cups at points of vantage adds materially to the insurance feature, so that the probability of trouble due to lubrication, or noise due to undue wear of the parts, is avoided. The weight of the automobiles in proportion to the available power in each case has been fixed with a view to good road performance, and the harmonizing of the relations of the functioning units has been brought about by a careful study of the needs in the light of experience.

Charging for Repairs Not Ordered

Some garage owners have contracted the habit of overhauling their patrons' cars without authority, rendering a stiff bill, and holding the cars in the event of a refusal on the part of the owner to pay.

REFORMS come under the press of necessities, and the men who keep their automobiles in public garages are being impressed with the fact that the rental charge is but a small percentage of the total of the bill in some cases, due to the success with which garage repairmen find troubles in the cars of their patrons and to the further fact that work is done in the correcting of these troubles perhaps too soon. In the long run the owner of an automobile is bound to count the total cost, and it should not take him more than a year or two to arrive at the conclusion that a $300 garage in his own back yard, under the charge of a machinist-chauffeur, is a better investment than paying $30 per month to keep his car in a garage and an extra $100 per month to cover the cost of mysterious repairs that he never orders. Every owner of every automobile that is kept in a public garage should serve notice upon the proprietor of the garage that he will pay no bill whatever for any work done unless he delivers a written order for that work to the owner of the garage. In the meantime, there is a law upon the statute books of the State of New York which protects the owner of the garage from "bad pay," it being within the law for the owner of a garage to seize a car and hold it in his possession until the owner thereof pays for any repairs that may be made upon it. This law was intended for the worthy purpose of protecting repairmen from "dead beats," but here and there information comes to hand which goes to show that some garage repairmen undertake to overhaul automobiles that are stored in their establishments without getting permission from the owners of the cars, and they force the owners to pay for what they do not order by holding such automobiles ostensibly under this law until the repair bills are paid.

Blue Book Cars Under Way

Opening Up New Fields and Improving Past Endeavors

In order to cover as much ground as possible three Blue Book cars are now under way. This is one month earlier than in preceding years. Many new roads have been built during the last season and it is proposed to include these in next year's volumes. Another volume will be added to the 1912 list, making five in all.

IT is not so many years ago that the routes of America were comprised in one volume, but since 1907, with the aid of a fleet of cars, the territory has been enlarged annually, and last year's four volumes were a great improvement on the preceding years' production.

This year the fleet of three cars is starting one month ahead of previous years' schedules and will remain in the field of useful endeavor until the snow flies. The object of the three cars is to cover as comprehensively as possible previous routes, and besides planning new routes they will plot the new State highways that have been made during the last twelve months. These are becoming an important factor, as the good roads germ has taken hold of most rural districts, whose inhabitants grasp what the automobile has done for the sections where automobile traffic has been opened through the roads being put in proper repair.

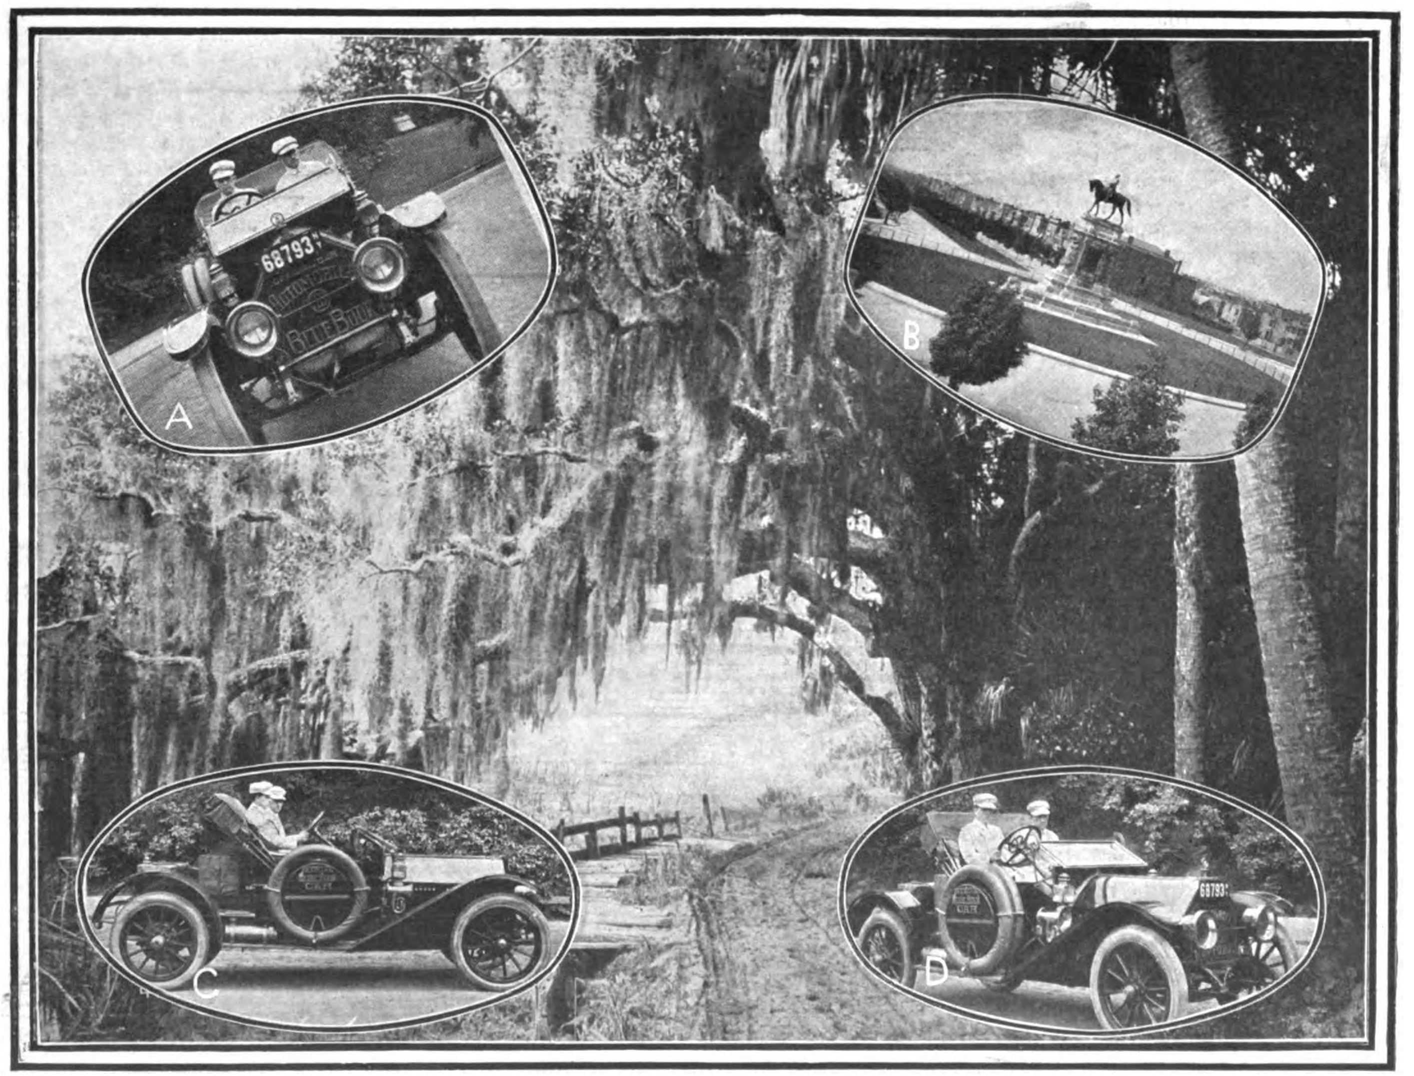
The Blue Book was started in 1901, and with yearly additions was, as before stated, comprised in one volume till 1907, when two volumes were found necessary. In 1908 it was enlarged and the three volumes which were published were highly appreciated by tourists. In 1910 four volumes were required to give the information on the territory that had been covered and many useful maps were added. The 1911 season saw the same number of volumes as the preceding year, but the information was largely added to and the usefulness to the tourist greatly enhanced. This year will see another addition in a volume which will comprise routes from the Mississippi to the Rockies, with extensions to the coast of the Pacific.

The car shown in the accompanying illustration will cover the ground included in Volume II of the Blue Book which comprises New England and Canada. This has been the favorite ground of many Eastern tourists, and it is expected that the car will cover 20,000 miles before taking to winter quarters. Much new ground will have to be gone over and it is the endeavor of the pilots to increase the fund of information as much as possible.

Car No. 2 will cover the territory included in Volumes I and III, which comprises the Province of Ontario and the State of New York. The volume covering Pennsylvania, New Jersey and the South is expected to be greatly improved, as the car will take advantage of the southern winter to extend its field when the other cars will be compelled to stop. This car is expected to cover somewhat over 25,000 miles.

Car No. 3 will take Volumes IV and V in hand, which includes from the Ohio to the Mississippi and from the Mississippi to the Rockies respectively. The schedule for this car is 30,000 miles, the additional mileage being due to the distance between the various towns. Extensions to the Pacific Coast will be included in Volume V, which will lead to a further extension in the future to the additional Volume VI, which will cover the Pacific Coast. The three cars will be distinguished by the signs placed on the radiator and sides of the cars.

SYNTHETIC RUBBER—It must be a long time before synthetic rubber seriously affects the price of rubber, but it has to be reckoned with. Dr. Gerlach has been giving his views on it before the Rubber Commission recently appointed by the German Colonial Agricultural Committee, and they are worth noting. In the beginning Dr. Gerlach was skeptical as to its value, and was very much surprised when bulk samples satisfied him that synthetic rubber possesses the essential properties of high-grade material. To what extent the new product will compete with natural rubber remains to be seen. The raw material of synthetic rubber is itself a manufactured article, the production of which, on a large scale, can only be undertaken by a few chemical firms, but there can be little doubt that artificial rubber will eventually appear on the market as a commercial product. Dr. Gerlach thinks that makers will take care that the output is not on a scale sufficient to depress the price of rubber. However that may be, producing costs will have to be largely reduced before serious competition with natural rubber is possible.—*Royal Society of Arts Journal.*



Three new Blue Book Good-Roads surveying cars started this week on a 75,000-mile mapping tour

Cause and Cure of Motor Car Noises

Knocks, Squeaks, Hisses and Pops That Worry

Detailing some of the common causes of noisy operation of the automobile's mechanism, and how to locate the components at fault, Victor W. Page, M.E., instructively discusses them from the viewpoint of the owner-driver, and suggests remedies for each of the annoyances. Taking the various systems of the automobile in turn, he points out the causes of noise in the respective parts and tells how they may be overcome, concluding with an interesting paragraph or two on hard-to-find knocks and squeaks that are due to unusual causes.

ONE of the most annoying conditions that may become manifest in connection with automobile operation, and one most difficult to detect by the average motorist, is that of noisy action while the mechanism is in use. This is especially worrisome because of the difficulty which obtains in tracing the noise to its source.

It is hardly possible to build a motor vehicle entirely free from noise, but it is not difficult to keep the mechanism so well adjusted and lubricated that the most distressing sounds will be entirely absent and only minor clicks, such as result from the clearance between the valve operating plungers and the valve stems, or the hum of the motor timing gears, will be noticeable. Some knocks presage rapid deterioration and untimely end of the part, indicating its distress, while others of equal magnitude do not foretell anything of import, being caused by looseness of some relatively unimportant part.

To be able to tell when a portion of the mechanism is defective by the sound is a knack that can only be acquired by experience, but some general rules can be given so the average motorist may become sufficiently expert to distinguish between the various noises, locating troubles by systematic search rather than the haphazard manner in which they are usually sought by those who do not have much mechanical experience.

Considering the power plant first, we find that the sounds commonly heard may be divided into four classifications, namely, pounding or knocking, squeaking or grinding, hissing or puffing and popping. Knocking is usually due to wear in bearings or looseness between other revolving or reciprocating parts. Squeaking is usually produced by contact of dry metals which are in motion relative to each other, and is an almost infallible indication of faulty oiling. A hissing or puffing sound always indicates a leak of gas under pressure, while a whistle generally shows that gas is blowing by a loose packing, or air is inspired in the engine at some point that should normally be tight. Popping noises may be evidenced at the carbureter or muffler, and are usually produced by conditions which make for imperfect combustion or slow burning of the charge.

The bearings which deteriorate soonest are those of the connecting rods; both the journals at the crankpin and those at the wristpin will wear in time even if well lubricated. The wristpin bearings have but a limited movement as compared with those at the lower end of the connecting rod; the pressures are great, the temperature high and the lubrication is not so positive as at the crankpins, so these bushings often fail before those of the lower end become loose.

Any looseness of the bearings will be manifested by a sharp metallic knock, though pounding does not always indicate that these parts are in poor condition. Deterioration of the connecting rod bearings is detected by removing the side plate of a one-piece or barrel-type crankcase or the bottom of a two-piece engine base and then endeavoring to move the rod up and down by the hand. Any play denotes lost motion, and, while a certain amount of movement along the horizontal axis of the shaft is permissible, there should be no large amount of vertical movement. The main bearings may be tested by raising the shaft by means of a jack placed under the flywheel or a lever fulcrumed upon the frame side member if the construction permits. If a lifting jack is utilized it should be so blocked up that the lifting ram is brought in contact with the outer periphery of the flywheel or one of the throws of the crankshaft, and any movement of the shaft will be clearly indicated by that of the operating lever.

If the pistons have become worn and the cylinder bore is greater at those points of the piston travel where the side pressure against the cylinder wall due to connecting rod angularity has been greatest, a considerable side movement of the piston is possible, the resulting pound being very much the same as though a bearing was loose. Another very common cause of knocking is a carbon deposit in the combustion chamber which tends to produce early firing or preignition of the compressed charge. This condition is due to lubricating systems which deliver the oil in such copious quantities that portions of it work up past the piston rings and burn because of the intense heat of the explosion. The deposit becomes incandescent at certain points and explodes the gas before the electric spark which normally performs that function takes place. Another way in which carbon deposits may cause preignition is by reducing the compression space in a motor which normally has a high compression. An eighth of an inch deposit on the piston top and a corresponding amount in the cylinder head would decrease the compression space by a quarter-inch, and thus even a very slight variation from the normal condition might cause early ignition.

An uncommon cause of knocking is due to the flywheel loosening on its shaft, although the later methods of fastening make this an unusual occurrence. On many of the older engines the flywheel is secured to the shaft by a large Woodruff key, or a gib key. If this is not fitted with extreme care the flywheel loosens on its fastening and the reduction of width of the key or the augmented size of the keyway produces a certain amount of lost motion, which results in a pronounced knock every time the flywheel comes in contact with the key. Even when the flywheel is bolted to a flange forged integral with the crankshaft, there may have been some carelessness in fitting the retaining bolts or in machining the bolt holes, which would permit the fastening means to loosen and the flywheel to shake and thus cause a metallic knock.

Loose cams on the camshaft, loose timing gears and worn gear teeth often cause pounding. Deterioration of the valve-operating mechanism generally produces a rattle, though if strong valve springs are fitted any lost motion in the timing gears, cams, valve plungers and even in the valve stem guides will make pronounced knocks, which become greater at higher speeds. The camshaft bearings, when of the plain bushing type, may wear and the lost motion produce noise, while many of the minor bearing points, such as the small pins of the overhead valve mechanism, loose tappets and rocker arms, or looseness of the roller at the bottom of the valve-operating plunger will in the aggregate produce considerable rattle, especially at higher engine speeds and with strong valve seating springs.

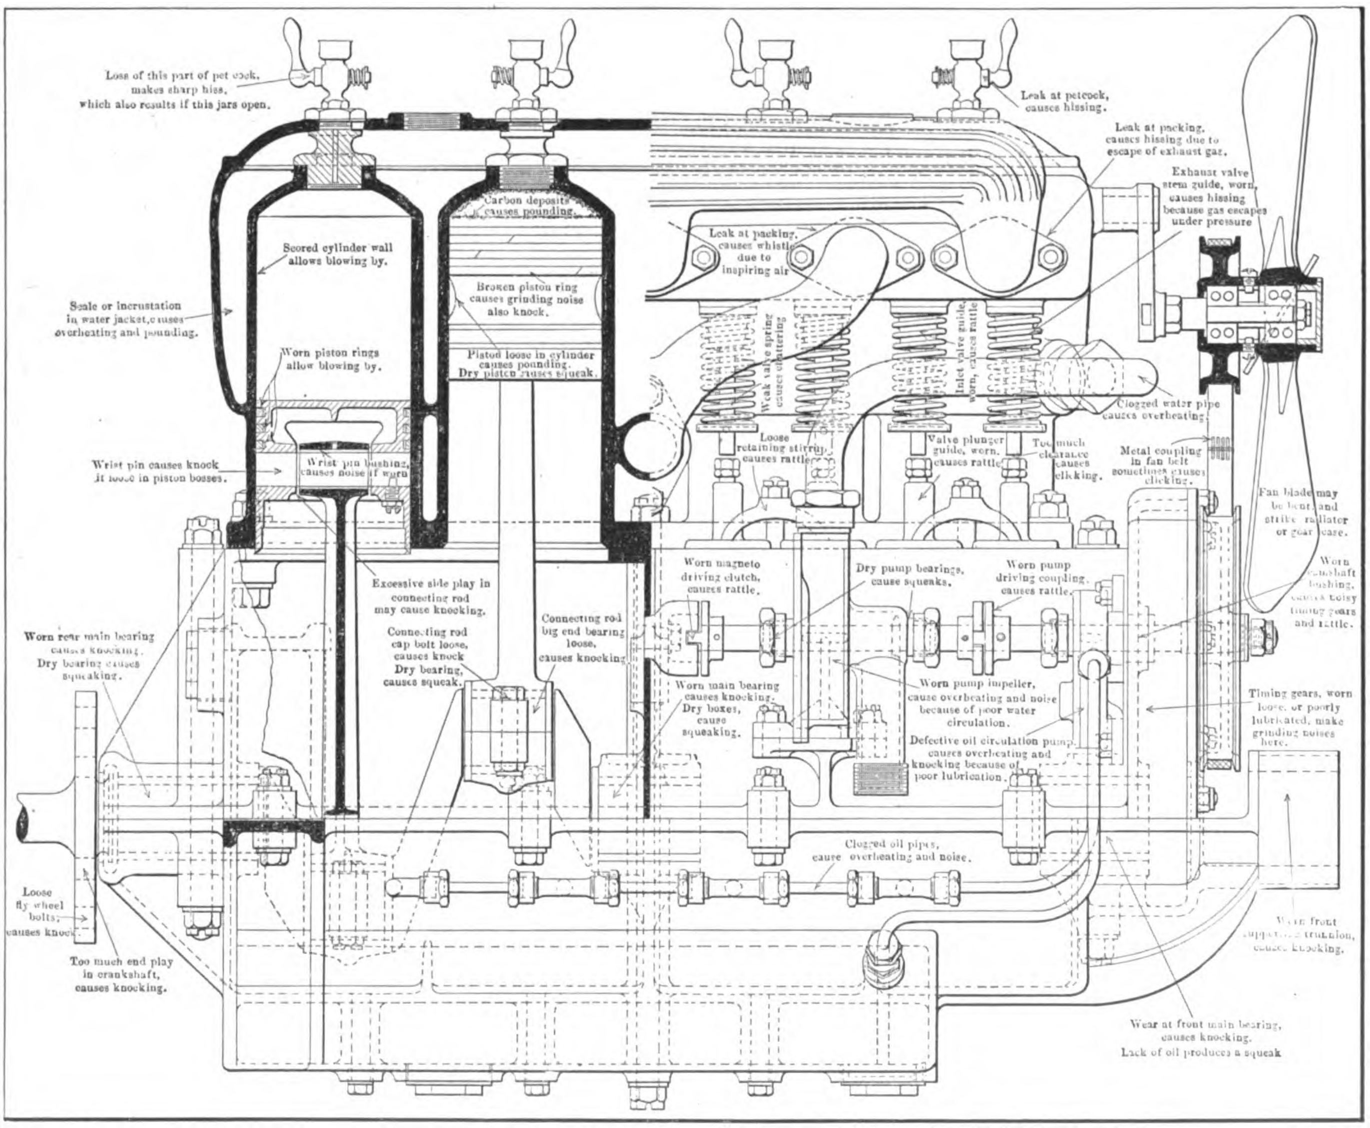
A severe pound is sometimes traced to faulty motor bed retaining bolts, which allow the crankcase to shake in the subframe or on the main side members. The shaking loose of the cylinder retaining bolts or nuts will cause a pronounced knock, and usually results in a broken cylinder flange if not promptly remedied. Sometimes a piston may be striking the end of the counterbore or shoulder left in some cylinders after machining; this condition often obtains when thin oil-retaining packings are inserted between the engine base and the cylinder flange instead of the thicker ones formerly used after an engine had been overhauled.

A bent or sprung crankshaft will impart a certain side shake to the connecting rod that will cause forcible contact between the sides of the wristpin bushing and the piston bosses during a certain portion of the revolution and bring the sides of the crankpin bearing against the crankwebs sharply enough to produce noise at other times. If there is considerable end motion of the crankshaft it may result in an irregular knock. The end of a connecting rod may hit a bolt or screw projecting into the case, or a connecting rod or main bearing cap or retaining screw become loosened enough to permit considerable play. A wristpin may be loose in the piston bosses, and there is always the possibility of some small parts, such as set screws, nuts, washers, split pins, etc., coming adrift and falling into the crankcase in such a position that some of the revolving parts will come in contact with them at times. In many engines of the single-cylinder type the counterweights fastened to the crank throw opposite the crankpin to balance the reciprocating parts may become loose on the retaining bolts and cause a severe knock. This condition demands immediate attention, for if one of the balance members becomes unfastened the crankcase is doomed.

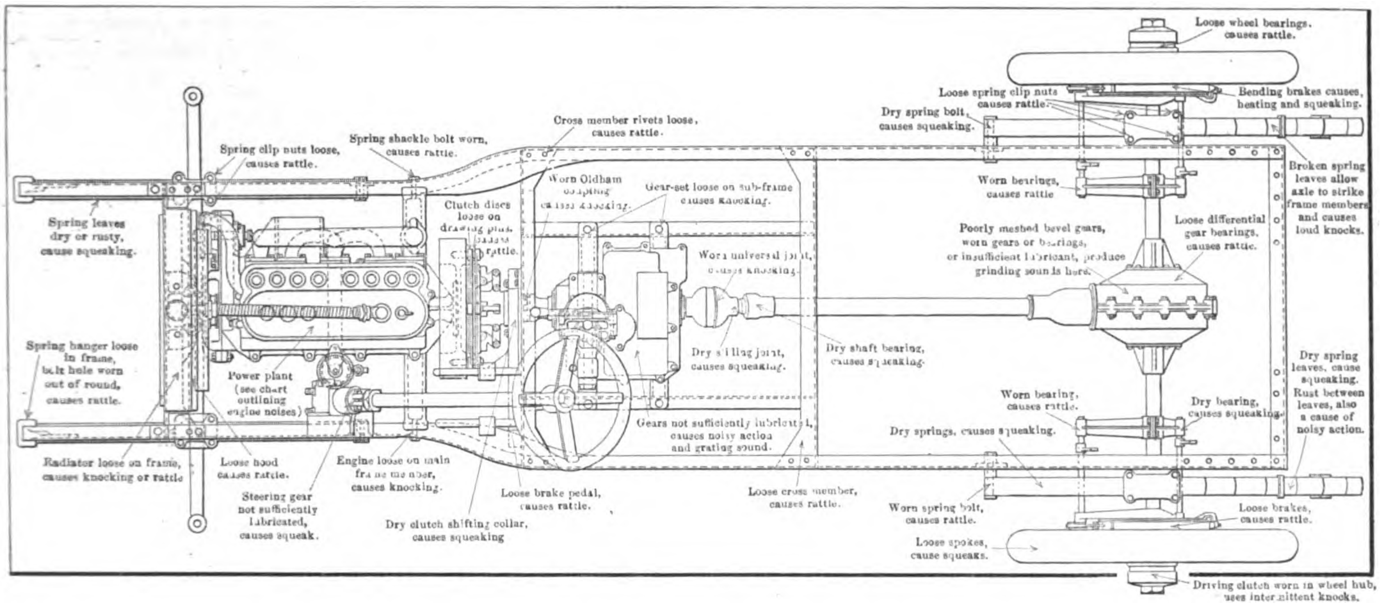
Sometimes, when the spark plugs are placed over the valves a long shell member may be inadvertently substituted for a shorter plug and a pronounced knock may result because of the contact of the valve head with the plug bushing. This should be avoided and care taken to use only plugs of proper length, because this forcible contact may spring the camshaft or bend the valve stem. A timing gear with worn teeth and loose upon its driving key may cause a combination of sounds that will lead one to believe that the end of the motor is near, while a broken ball or roller bearing will cause a combination knock and grinding noise that is hard to mistake for anything else.

Anything that will cause the motor to become excessively hot will produce a knock, and when overheating is due to poor oiling there will be squeaking or grinding noises denoting dry bearings as well. Failure of the cooling system will cause the motor to become so hot that the charge preignites and one has the same condition and sound as though the interior of the combustion chamber was full of carbon.

Another common sound that indicates faulty power plant action is a sharp hiss, and this can usually be traced to a leak in the cylinder above the piston top. The petcock used to relieve the compression and for priming may have jarred open, and it is not an uncommon occurrence for the shut-off valve part to drop out of the seat and allow the gas to escape. To remedy this



Longitudinal sectional view of a four-cylinder motor showing the relation of the various working parts with a view to the discovery and prevention of noises



Plan view of a chassis showing by means of notes the probable location of noises

a plug of wood may be made and driven in, or a repair extemporized out of a small bolt and a couple of washers if the missing part cannot be found in the under pan. A hiss may also be caused by a broken spark plug gasket or a faulty packing under one or more valve chamber caps, and a defective exhaust manifold gasket or lost retaining bolt that allows the gas to escape will also produce a hissing sound. A whistle is caused by escaping gas around a loose packing that acts as a reed. This sound may be produced either by inspiration or exhaust of gas and therefore any loose packing on either the inlet pipe, the exhaust gas conductor or the engine base may produce it. A small crack in either of the gas conductors will also produce a whistle —in the inlet pipe when air is drawn in at that point, at the exhaust when the inert gas is discharged through the very small opening. Leakage through worn inlet or exhaust valve stem guides will also cause hissing.

When a squeaking noise is heard look after the lubrication system. The main bearings may run dry, or the level of oil in the engine case may be so low that the interior of the engine is deprived of the oil necessary to insure smooth and continuous operation. Find out the cause of the squeak at once, for if bearings are run without proper lubrication they will burn out if of white metal or babbitt or seize and cut the shaft very badly if of bronze. Dry cylinders will become scored and the process of reboring that is necessary to restore their efficiency is much more costly than the price of oil enough to insure proper oiling for several years. Impurities in the oil may cause grinding sounds by getting between bearing surfaces, and parts that fit too tightly cause a grind or squeak even when they are copiously lubricated.

A wheezing and scraping sound may be traced to the flywheel scraping against a projecting piece of the underpan in contact with it. A slight clicking sound may be due to the fan blades striking the radiator. A broken wristpin will often cause both pounding and scraping sounds, the knock because of the lost motion in the bearing, the grinding sound because the end has worked out and is bearing against the cylinder wall.

A broken piston ring often causes a scraping sound, as does a stuck piston ring which cannot move in its groove because of carbon accumulations behind it which force it against the cylinder wall. A very sharp squeak has been traced to a dry contact blade in the timer or contact breaker of a magneto; a dull squeak has been finally located in the timing gear case, being produced by the rawhide shrouding of one of the large gears swelling out and coming in contact with the timing gear case cover.

Another intermittent knock and grinding noise is sometimes caused by the governor weights striking the timing gear case cover when the engine was suddenly accelerated, and remaining in contact with it when the engine was run at certain speeds. When the motor was running slowly the weights were held in position by the springs, but just as soon as the speed was increased the weights flew out against the cover and produced a knock, afterward grinding as long as the speed was maintained that kept them in contact with other metal. If the shifting collar of a clutch is not properly lubricated it will squeak in a very pronounced manner, while wear in the driving connection will cause a sharp knock every time the clutch is released or engaged, as well as every time the motor speed is changed or regularity of torque interrupted.

Gearsets are apt to be noisy after they have been in use for some time—the planetary type on the low speed and reverse ratio, the sliding gear forms on all speeds. The design of the planetary gearset and the high speeds at which the small gears revolve tend to make for noisy operation even when the gear is new, and this condition is augmented considerably when it has been in use for some time. If sliding gears are properly made and handled there will be no undue noise, but as soon as the gear teeth wear, however, and the shaft bearings lose their correct adjustment, the grinding on the lower speeds will be very objectionable and a certain amount of noise will obtain even on the high speed, as the lay shaft and main driving member gears are always in mesh. When the keys and splines wear so that the gears are not rigidly held to the shafts the noise due to the teeth being worn out of correct pitch will be intensified. If the bearings lose their adjustment or become worn, the center distance between the gears will be changed and noise result because of improper meshing. Metal particles in the lubricant often cause grinding, and unsuitable oil, or a lack of lubricant, may result in noisy operation even if the gears are not worn unduly.

In some types of selective gearsets the amount of sliding movement necessary to engage any of the gears is very slight, and but very little lost motion is required to permit the gears to come in contact at the tooth edges while out of engagement and cause grinding or an intermittent knocking. Examine the locking balls or spring-actuated plungers that keep the parts in place and prevent motion of the disengaged members and see that they are functioning properly. If annular ball bearings are used, they are liable to make a clicking noise if there is a damaged ball or broken separator and grind if there is foreign matter in the races. If bearings and gears appear to be in good condition and the lubricant has proper viscosity and is clean, and still there is an objectionable grinding noise on the lower speeds, it is possible that one of the shafts is sprung and the gears are not meshed properly at a certain portion of their revolving movement.

Chain drives, unless properly encased and lubricated, are apt to be noisy except when new, and even then there will be a "singing" sound at high speeds. The grit and oil that collect on exposed chains cause the links to wear out of pitch, and, as the sprockets depreciate at the same time, it is not long before the drive is quite noisy. If the sprocket teeth become hooked and the chains are adjusted too tight they will "snap," while if too loose the chains will "slap" as well as grind. The small driving sprockets on the countershaft sometimes become loose on their fastenings, and a knock very similar to that of a loose bearing is heard every time the continuity of the drive is interrupted.

A very common noise emanating from shaft-drive rear axles is a grinding sound, which often becomes greater at high vehicle speeds. This is usually due to wear of the bevel driving gears; deterioration of their supporting bearings; lack of proper lubricant; foreign matter in the oil and very often to poor adjustment. Bevel gears will produce a harsh grinding sound when meshed too close together, and, on the other hand, if not engaged sufficiently there will be a rattle. A very common cause of rattle is loosening of the driving means at the wheels, especially on full floating axles where the hub is driven by a jaw clutch attached to the end of the axle shaft. If these become worn so there is lost motion between the driving dogs and the slots machined to receive them, the play will be evidenced by knocking every time the continuity of drive is interfered with. On some of the lighter live axles the shafts are supported on plain cylindrical roller bearings which bear directly on soft steel shafts and in a soft steel tubing axle housing. These cut through into the shafts and also remove considerable metal from the tubing interior. When the play becomes great enough there will be a pronounced rattle whenever the car is driven over Belgian block pavement.

It is not uncommon to trace a squeak to a dragging brake band, usually one of the internal brakes which has become covered with a deep enough accumulation of dust or grit to keep in contact with the drum. Poorly adjusted brakes will also cause the same condition, but care should be taken not to have these members too loose or there will be a rattle instead of the squeak.

A loud knocking is often traced to worn universal joints, which have so much lost motion between the cross and the driving pins, and often between the yokes and the center member that the parts are brought into forcible contact with each other at every movement of the rear axle that causes even the slightest variation in driving shaft angle. This is especially true of unprotected universal joints, the dirt that works into the bearing surfaces causing rapid wear and considerable noise. In this connection it is well to call attention to the pronounced knocking, very much like a worm engine bearing, that results from driving torque or radius rods when they show wear at the points where they are fastened to the frame or axle.

Most of the components comprising the chassis assembly are held to the frame by bolts and nuts instead of rivets because of the necessity which sometimes arises for their removal for repairing. It is not infrequent that common machine and carriage bolts are used as fastenings, and as they loosen they naturally tend to produce a rattle. Rivets sometimes loosen and a subframe or cross-member supporting some heavy member such as the power plant or gearset becomes loose and produces noise.

The brake operating rods and various links of the control system are sometimes carried on the frame in such a way that they come in contact with the frame members and produce a rattle. Very often these are passed through holes in the frame members and squeak because of the dry metallic contact whenever they move longitudinally and rattle with every frame movement. Lost motion at spring shackles causes sounds that are not pleasing and dry springs produce squeaks that are distressing and very easily prevented. When spark-and-throttle control shafts pass through the center of the steering column, these may become rusted slightly or not have sufficient oil, and every time the steering wheel is turned or the engine speed varied a squeak is heard that is often hard to locate. Various points on the front axle may wear or get out of adjustment and produce their distinct little rattles that contribute to the general din. The tie-bar and drag-link yokes or ball joints may have considerable lost motion, the steering knuckles may be loose on the yoke pins and the ball bearings may be worn or out of adjustment.

Noises are sometimes located in queer places that one would never suspect. For instance, a pronounced squeak was found due to the opening of several of the joints on the sills of a wooden body after all points of the mechanism had been carefully gone over with an oil can. A knock that was searched for in vain in the engine was finally located at the gasoline tank, which was adrift on the frame; another that suggested loose connecting rod big ends was eventually discovered in the muffler, where a baffle plate had become loose on all its retaining rivets except one at the top, which permitted it to swing back and forth like a pendulum at every impulse of the motor, and thus produce a rhythmical knock usually attributed to a defective engine bearing. A dry water pump stuffing box produced a squeak, while a clicking noise that was searched for in vain for several days was discovered in the fan belt, which had a metal fastener that produced a little metallic knock every time it went over the fan pulley.

Every point where movement is possible should be well fitted and have a minimum of lost motion; the mechanism must be kept clear of the abrasives that work into the bearing points and produce untimely deterioration, and all joints, no matter how unimportant, should receive oil. All loose rods, wires and parts should be firmly fixed; every nut should have some kind of positive securing means to insure against loosening by vibration; pipes should be kept tight; broken packings and gaskets should be replaced as soon as they give evidence of leakage, and, above all, the engine bearings should be kept adjusted to that point where the power plant will be silent in action.

In the Fitting of the Top

One or Two Points That Are Generally Overlooked

George J. Mercer offers a few suggestions to the automobilist who desires a top fitted to his car, nor would it be out of place to observe that the top maker would be the proper authority to advise the owner to get a good top while he is about it.

WHAT the public sees when an automobile goes by is everything that intercepts the line of vision, including the soiled appearance of the fabric of a top, if the material used therein is of the class that picks up dirt and holds it in the mesh of the weave. What the owner of the automobile experiences includes a most unpleasant sensation if the top soils readily and belies the quality of the car despite effort. It is not uncommon to see fine examples of automobiles sporting tops that cost enough to be good, but it is a great misfortune that purchasers of automobiles put in too much time discussing the several phases of their ideals to the high disregard of the kind of material that is used in tops and of the fact that the ironing of a car for the top is something to be given serious consideration, and referring to Fig. 3 of a side elevation of a top fitting on a fore-door type of automobile it is pointed out that the iron, if it is placed at E, is in exactly the right position to be struck against by the elbow when the driver of the automobile slides the gears or puts on the emergency brakes, and it is not too much to say that an interference of this character at a critical moment may be the foundation of a serious accident. But if the iron is placed at F instead of at E there is nothing to prevent the proper working of the top, and the occupants of the front seat will have a clear view of the surroundings without having to peek around an interfering member. Moreover, the idea of interference during the sliding of the gears or the working of the emergency brakes will be done away with.

Still another point that is sometimes overlooked is coupled with the idea that the head room D does not have to be so very much since it is customary to hold to a stooping position during the operation of getting into a car, but there is no reason why the diagonal support of the top should be so slanted as to interfere with the head room at the point G. It is certainly possible to so locate the iron H that the diagonal brace at the point G will come in the plane of the back sill of the rear side entrance.

In the three figures given there is ample opportunity to observe the relations as they hold between the side elevation, top and rear view. Success in the fitting of a top begins with the proper placing of the irons and referring to A and A′ in Fig. 1, the rear top irons are indicated, showing how they are fashioned to support the top when when it is folded down. At A the fabric is cut away and the iron is shown in its position far enough to the back so that the socket is level with the widest part of the seat trimming, measuring about 27 inches from the center line in this example, and referring to A′ at the right side of the body this iron is shown as H in Fig. 3, occupying the forward position, in which the distance from the center is approximately two inches greater than the same distance for the back irons. This increase in distance is due to the placing of the front irons H at the widest point of the body, and it is suggested that the body designer should have in mind the suitable location of the irons at the time of laying out the body.

Proper clearance should be given between the inside of the bow when down and the outside of the socket iron at A′, and experience seems to show that a distance of four inches will be sufficient, making the top clear at A′. In selecting tops for the various makes of automobiles the observance of a due measure of clearance may dictate the use of bent bows in some cases, but it is well to guard against the outward swelling of the bows too much, and here again there is opportunity for the designer of the body to settle the problem of the fitting of the top, avoiding tight situations, catering to appearance and utility at the same time.

There are two broad considerations that are present in the fitting of tops, one of which has to do with the top when it is up and the second point deals with the top when it is folded down. Strange to relate, most tops give trouble when they are in the folded-down position. This is due to the fact that the irons are not placed far enough back to carry the load without putting undue work upon the bows, and this difficulty is accentuated by selecting tops that are higher than there is any occasion for having them. The illustrations here given show by measurements indicated just what can be done in the matter of fixing clearances and arranging for the proper support of the weight, and if these matters are properly attended to the remaining considerations will have to do with the proper selection of the bows and the fashioning of the irons, having in mind the idea that the irons should be securely bolted to the frame of the body, and for the rest it is a mere matter of picking out a good grade of fabric that will match the outward appearance of the car, keep out the rain and resist dirt.

It would be a step in the right direction were it against the law as it is against honesty to apply false descriptions to the fabrics that are used in this class of work. It is marvelous what a large number of fabrics there are that are called mohair without due license. It is also true that the mohair used in many instances is too thin to do good work. The purchasers of automobiles should specify genuine mohair weighing about eight ounces to the yard, if this type of material is to be used in a top, and there is no reason why an Angora goat should be discriminated against by having imitation mohair foisted upon a purchaser simply because it is difficult to tell from appearance the difference between genuine mohair and "lustre wool." It is not the purpose here to contend that lustre wool fabric is too poor to use in a certain line of work, but it is proper to say that lustre wool fabric should not be sold to a purchaser as genuine mohair.

The main difference between genuine mohair fabric and that of wool is represented in the better life of the mohair, the greater protection it affords and the further fact that the hard wire-like thread of the mohair works into a fabric that will not hold dust, there being nothing for the dust particles to cling to. Beyond selecting the types of fabric that will afford the requisite protection and retain a good appearance for a long time there still remains the necessity of protecting the top against accumulations of dust by having the cover properly fitted, especially at the front end, and the idea that anyone should put up with a "baggy" looking affair as a substitute for a real top is too ridiculous for serious consideration.

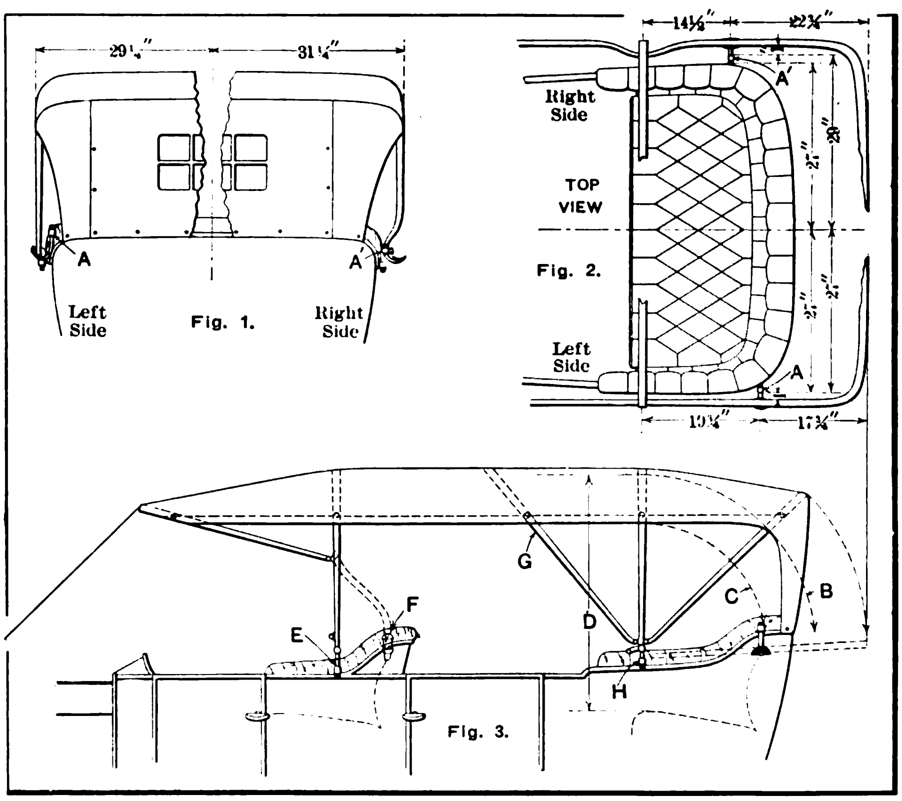


Fig. 1—Rear view of a properly fitted top showing the positions of the irons at the back and side
Fig. 2—Plan of the top showing clearances of the bows in the folded down position
Fig. 3—Side elevation of the top in the up position suggesting elbow clearance by placing the iron at the front seat far enough back to properly serve the purpose

When Judgment Whispers Don't

DON'T overlook the damaging effect of extreme conditions of heat upon rubber tires.

DON'T drive too fast on a hot day, even automobiles experience a depressing effect if the weather is warm.

DON'T stand the automobile exposed to the blazing heat of the sun; it will blister the finish.

DON'T use light body lubricating oil if it must resist the heat of a Summer's day and do its work besides.

DON'T overlook the sensitiveness of a machine to heat and cold; expansive effects must be taken into account.

DON'T tax the adroitness of a good automobile in the production of dust to the annoyance of an antagonist.

DON'T try to make your neighbor eat dust; if you think it is a healthy diet take your fill of it.

DON'T interpret liberty as meaning that you have the right to practice the artifices of a road-hog.

DON'T pass a brother automobilist on the road if he gives a distress signal; you can well afford to stop and see what he wants.

DON'T annoy the blue-coated guardian of the peace; he will not care to sprint as fast as your automobile may be forced to go.

DON'T practice antagonism when the weather is warm; the judge might give you a limit fine.

DON'T miss the opportunity to splash water on the tires if the day is hot; it will cool them off and add materially to their stamina.

DON'T embarrass the motor by running on a retarded spark; the radiator will catch the disorder also if this practice is indulged in.

DON'T poke fun at a brother automobilist if you catch him trying to pump up a tire with a toy pump.

DON'T attempt to crank an overheated motor without approaching it in due and diplomatic form.

DON'T crank with the right hand if you can do the work with the left.

DON'T push down upon the crank—it is safer to pull up.

DON'T forget to retard the spark before cranking.

DON'T count too much upon the unconstitutional features of bungling legislation—your curiosity might cost you more than a dollar per pound.

DON'T start out with a pint of lubricating oil and the promise that you will get some more at a convenient garage—a burned-out crankshaft bearing might greet you before you get to the garage.

DON'T forget that the police interpret the law, and also decide its fine points.

DON'T employ the languid method of cranking a motor—it might get mad and inject some ginger into you.

Antipodean Automobiling

Australian motorists are much interested in the question of self-starters, several new systems having been evolved during the past year. The automobile is an aid in opening up the country. Australia affords touring ground which in point of interest and scenic beauty is second to none in the world.

AUSTRALIA is manifesting deep interest in what automobilists term "the direction of the self-starting motorcar engine," as revealed by the introduction of several new systems evolved during the past year. The engines include methods for compressing carbureted gas into the cylinders by artificial means, in order to secure an initial charge; methods of forcing the engine to turn past one or two firing points by means of compressed air, and also methods purely mechanical in their nature.

There is an estate of many thousand acres of wild and wooded, roadless land in Australia, whose owner has just received ten automobiles from England. He had these machines constructed after his own designs. These contained numerous stipulations, especially these: The machines were required to be equipped with gears for stationary work; be provided with a winch for hoisting or pulling them out of soft ground; have a sufficient clearance to negotiate several feet depth of water; and be capable of going at a reasonable speed.

The Upper Murray Mountain in Australia affords innumerable attractions for automobilists, rugged, ragged and danger-wrought though this mountain is. The route is from Wodonga to Talgarno, passing through Jingellic, Walwa, Tintaldra, Gorryong, Wabba, Berringama, Koetong and Tallangatta. Not alone Australians, but also around-the-world tourists take advantage of this wild, romantic, mountainous highway, many parts of which have been rebuilt expressly for automobile travel.

The Motor Car Act now in force in Melbourne carries with it the obligation that each driver's license shall bear the endorsement of a Police Court Magistrate on the reverse side. One captious critic, chafing under what he declares to be an unfair custom, says that "licenses thus disfigured are standing evidence, as far as they apply against the efficiency of the holders, as motor car drivers, who even were they nominally at fault in the first instance may now be ranked among the experienced and most careful drivers."

The Effect of Silicon on Steel

By E. F. Lake, M. E.

Silicon in steel is as beneficial in its effects as silicates are undesirable, and this article treats of the correct method of incorporating the metalloid in steel and of repelling silicates. By means of this ingredient corrosity of iron and steel may be overcome and the formation of blow-holes thwarted, but a considerable amount of care is necessary in the manufacturing of siliceous steel using either silicon or its alloys with iron and manganese in exact proportion in order to avoid destroying the good qualities of silicon steel.

THE wide application of silicon was only begun when the electric furnace made it possible to obtain ferro-silicons that were rich in silicon. The importance of this metalloid in metallurgy has shown a steady increase since that time, in that its addition to iron, steel, aluminum and so forth has proved to be very beneficial, and doubtless other benefits from its use will be discovered in the future.

Silicon forms 27.21 per cent. of the earth's crust and is the second most important element, oxygen being first. As it has a great affinity for oxygen it occurs chiefly in the form of silicon dioxide, SiO_2, which is commonly called silica. It is never found

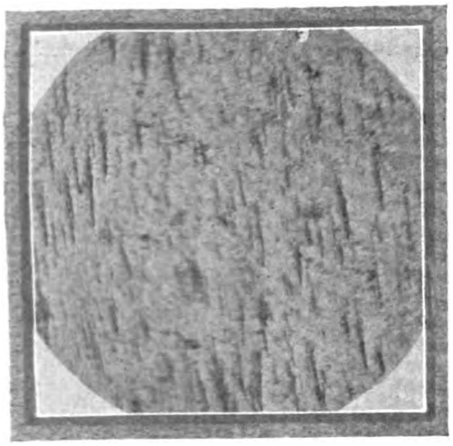

Fig. 1—Fibrous structure of silicon steel, magnitude 300 diameters

in the free state in nature, but besides the silicon dioxides forms silicates in combination with oxygen and some metallic elements. Silica neutralizes every base it comes in contact with when molten, and all metallurgical slags are the silicates thus formed. For steel making the silicon has to be separated from the oxygen of the silica and united with iron to form ferro-silicon.

Silicon is a non-magnetic metalloid, while iron constitutes the typical magnetic metal. Each increase in the percentage of silicon that is added to iron decreases its magnetic attraction. When the silicon reaches a high percentage it makes iron practically non-corrosive and thus it has been possible to use irons containing from 15 to 20 per cent. of silicon in the construction of drainage pumps such as are used around salt water, and also for the bilge pumps of ships. At these high percentages there is a distinct antagonism between the silicon and carbon and each increase in the silicon's percentage is accompanied by a diminution of that of the carbon. With this decrease of the carbon numerous cavities are formed that are filled with the graphite dissolved from the carbon in the iron during fusion. The carbon is subsequently almost entirely separated while the metal is cooling.

The effect of silicon on steel is not yet thoroughly understood. When Bessemer steel has silicon left in it, it indicates that the metal had been blown too hot. Such metal is apt to be brittle. To get the best results in steel the silicon should be eliminated as much as possible when purifying the bath and the definite quantity required should be added in the form of ferro-silicon or ferro-manganese-silicon. This gives a much different effect from that of silicon left in during the process of manufacture. When silicon is added to steel in a manner that will cause it to enter into solution as silicide, it confers upon the metal valuable properties, but when it forms a silicate it is injurious in many ways, even to the point of being dangerous. This occurs as the silicates of iron, manganese, etc., but these usually dissolve into each other and go off into the slag; although manganese-silicate propably causes more failures in the steel than is generally supposed.

Silicon is one of the best elements with which to prevent the formation of blow-holes in steel, as it has a great affinity for oxygen and seizes this wherever found whether in the form of gases, oxides or dissolved oxygen, and carries it off into the slag. It thus makes the steel harder and tougher and better able to withstand wear and crushing from continual pounding. One steel maker discovered that if the percentage of manganese plus 5.2 times the percentage of silicon was made to equal 2.05, the metal would be entirely free from blow-holes, but the pipe would be large. If the total was made to equal 1.66 per cent. the pipe would be smaller and numerous minute blow-holes would appear, but not enough to harm the steel for most uses. It was also found that 0.0184 per cent. of aluminum would have the same effects as 1.66 per cent. of manganese and silicon.

In the Bessemer converters silicon increases the temperature of the bath and hence a pig iron that is low in silicon will cause the blow to be shorter than if it were high. At the end of the blow 0.2 per cent. of silicon is added to rid the bath of gases. In the crucible process the steel absorbs silicon during the "killing" and thus becomes sound by throwing off the gases. Too long "killing" makes the steel brittle, owing to its absorbing too much silicon, the graphite crucibles usually used in this country give up more silicon than clay crucibles, and for this reason allowances have to be made when charging.

When quenching steel the influence of silicon is similar to that of carbon in many ways. To some extent it neutralizes the injurious tendencies of manganese. The resistance to shock of silicon steels in the direction of lamination is remarkable owing to their extremely fibrous formation. They have practically no resistance, however, in a direction perpendicular to the laminations. They are thus especially adaptable to the manufacture of leaf springs. This fibrous formation gives the appearances that are shown in Figs. 1 and 2 when the steel is examined under the microscope.

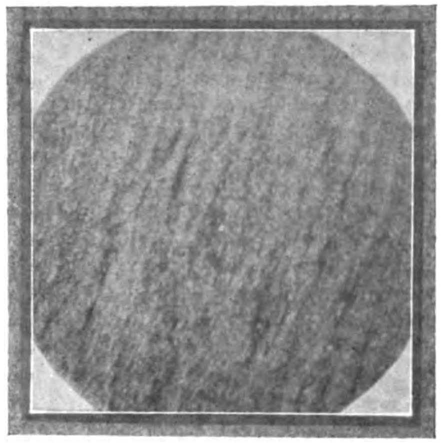

Fig. 2—Fibrous structure of silicon steel, magnitude 300 diameteis

Up to about 4 per cent. of silicon each increase in the percentage of silicon in steel slightly raises the tensile strength and lowers the elongation and reduction of area. The tensile strength increases about 80 pounds per square inch for each 0.01 per cent. of silicon, but beyond 4 per cent. a weakening seems to take place unless the manganese is high. Silicon steels will show very low shock resistance whether annealed or quenched, unless they have a high manganese content. With a silicon content of 0.20 per cent. the tensile strength is increased about one-third more than it would be with 0.01 per cent. of carbon.

With few exceptions the steels that are now used in automobile construction contain from 0.10 to 0.30 per cent. of silicon. In place of carbonized gears commonly used in the transmission case, a few motor car builders used a silico-manganese steel that contained about 2 per cent. of silicon, 0.70 per cent. of manganese and 0.50 per cent. of carbon, with the phosphorus and sulphur below 0.40 per cent.

Hard tool steels that contained slightly less than 1 per cent. of carbon have been made with from 1 to 2 per cent. of silicon and these have been used quite successfully. Steels have also been made for several purposes that had a silicon content as high as 5 per cent. With a silicon content higher than this steels have found very little use. When the silicon content is below 1 per cent. silicon ceases to have an influence on quenching and the magnetic property of iron is not decreased to any appreciable amount, hence such steels are not mentioned as silicon steels.

POINTERS CONCERNING ACETYLENE LAMPS—Copper tubing is considerably used for piping acetylene gas to the burners, but it is liable to erosion by the gas, and standard 1-8-inch gas pipe is better and lasts longer. The gas bag and rubber lamp connections should be kept clean and not painted, as is often done to correspond with the car, as paint rots the rubber, with the result that it is soon unserviceable and must be replaced. When the rubber is to be washed, only water should be used and it should be carefully dried before putting in service again.

HOW CAR OWNERS MAY "TURN AN HONEST PENNY"—Some enthusiastic English people are in favor of devoting the automobile to a unique use, as an endorsement of the proposition of "a lady in reduced circumstances," namely, to put her own private car at the disposal of parties desirous of attending at-homes and after-theater parties. Of course, such obliging service would be done "for a consideration."

What Some Subscribers Want to Know

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their automobile troubles, stating them briefly, on one side of the paper only, giving as clear a diagnosis as possible in each case, and a sketch, even though it may be rough, for the purpose of aiding the Editor to understand the nature of the difficulty. Each letter will be answered in these columns in the order of its receipt. The name and address of the subscriber must be given, as evidence of good faith.

Axle Shows Signs of Sagging

Editor THE AUTOMOBILE:

[2,735]—I noticed a sketch in your paper recently with reference to axle sagging, and it tallies with some trouble I have had. The rear wheels do not run true and it seems that the casing has taken a slight set. Would it be possible to put the matter right by fitting a tie rod? How is this attached?

The method of attaching the tie rod is shown in Fig. 1. A bracket must be fitted to the casing C' and the tie rod slipped through the hole and a nut N fitted each side of the bracket holding the rod in tension. Even when these rods are fitted drivers do not make proper use of them. Owing to the bending strain that is imposed on the metal it tends to stretch slightly and this must be taken up in the adjustment. In most cars provision is made for the attachment, but in case it has to be fitted afterward the bracket may be made in two halves and bolted over the casing C'. In addition it should be soldered or brazed.

A Most Unpromising Undertaking Indeed

Editor THE AUTOMOBILE:

[2,736]—Will you please tell me who is the best party to weld a crankshaft?

M. G. JOLES.

Oneonta, N. Y.

Considering the fact that the crankshaft broke in service, if it did, remembering also that a welded section is never as strong as an original section, we fail to see any promise in an undertaking such as this. It might be more to the point to get a new crankshaft.

Put a Baffle Plate at the Open End of the Cylinder

Editor THE AUTOMOBILE:

[2,737]—At times the right cylinder on my 12-horsepower horizontal opposed offset motor sucks in so much oil that the spark plugs foul up every mile or two. Sometimes it will run 100 miles without a particle of trouble, then again will bother for a week and seems to right itself. I clean the cylinders thoroughly very often. Oiling system is automatic splash, amount of oil in tank seems to make no difference.

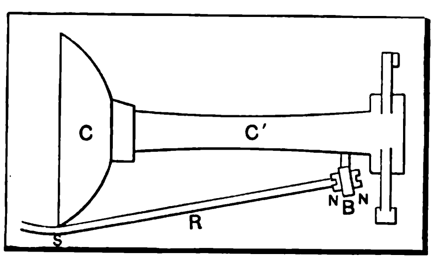

Fig. 1—Showing how the tie rod is attached to the axle to prevent the same from sagging

Can you suggest any way out of the difficulty? PERPLEXED.

Worcester, N. Y.

Horizontal types of motors sometimes give trouble of the type as complained of by you, and it is not unusual to fit baffle plates at the open ends of the cylinders, these plates being of sheet iron or aluminum flanged to the diameter of the cylinder with a slot cut across the disc of a size that will permit of the play of the connecting rod. The fitting of a plate of this character is not a difficult undertaking, and it has the advantage of being the certain cure for the disorder.

Method of Replacing Ball Sockets

Editor THE AUTOMOBILE:

[2,738]—I find that the ball socket of the steering arm of my car has worn considerably. Can I have this replaced without having a whole new part made? The car is not a modern one and I am afraid I shall

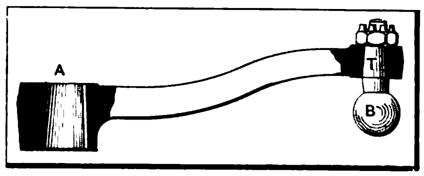

Fig. 2—Showing how a new ball joint can be fitted to replace a worn one

have some difficulty in obtaining a new part even if I wanted one. ANCIENT.

Norristown, Pa.

The method shown in Fig. 2 of attaching the ball socket should answer your purpose. It will be noticed that this part represents the drop arm of the steering gear and that the end is made large enough to drill and fit a taper bolt T with a ball B attached turned out of the solid.

After the part has been fitted it should be case-hardened. The wear you complain about was probably due to the old one not being properly hardened. The joint should be covered with a leather boot filled with grease.

Wants Information on a Variety of Subjects

Editor THE AUTOMOBILE:

[2,739]—Please answer the following questions through "Letters."

1. In what year did the Franklin engine contain concentric valves?

2. What are the objections to this type of valve?

3. How many Gordon Bennett cup races were run and what cars and drivers represented America?

4. What is the horsepower of the Only car? SUBSCRIBER.

Topeka, Kans.

1. Last year.

2. Nothing.

3. Years 1899, 1900, 1901, 1903, 1904 and 1905.

4. We have no record of a horsepower test of this car.

A Paste Called "Smooth-on" Will Help You Out

Editor THE AUTOMOBILE:

[2,740]—There are two small cracks in the water jackets on the third and fourth cylinders of my car, through which the water leaks slightly. How can I remedy this? I certainly will appreciate it if you will answer this question in your next issue. TROUBLE.

Lancaster, Pa.

For many years in foundries and like establishments it has been the practice to mix finely powdered gray iron with chloride of ammonia (sal-ammoniac) to form a paste, which, when applied to metallic surfaces hardens and after a few hours this paste assumes all the characteristics of cast gray iron, of which the cylinders are also made. If you will get a can of "smooth-on" and apply it agreeable to the directions supplied therewith, it will probably lift you out of your present dilemma.

Method of Withdrawing Jackshafts

Editor THE AUTOMOBILE:

[2,741]—Could you tell me how to withdraw the jackshaft from my rear wheel without taking the wheel off every time? The flange of the hub is extended out and the hub cap fits on to it. L. W. L.

Atlanta, Ga.

We should suggest you having the end of the shaft drilled and tapped to take an extracting tool similar to the one shown in Fig 3. By means of this it is possible to

What Other Subscribers Have to Say

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their personal experiences for publication in these columns for the worthy purpose of aiding brother automobilists who may be in need of just the information that this process will afford. Communications should be brief, on one side of the paper only, and clearly put, including a rough sketch when it is possible to do so, and the name and address of the writer should be given as evidence of good faith.

withdraw the shaft without difficulty. It may happen that in the fitting in the shops there are some marks on one of the teeth that engages with the hub forming the driving member and these should be looked for so that they may be replaced in the manner intended by the makers.

A Trio of Questions

Editor THE AUTOMOBILE:

[2,742]—I would like to ask the following questions through your valuable columns:

(1) What motor is used in the "Mercer" car manufactured by the Mercer Automobile Company of Trenton, N. J.?

(2) What manufacturer was the first to market a six-cylinder automobile?

(3) What cars did the "Correja" defeat in last year's hill climbs?

Newark, N. J. M. H. POTTER.

1. The motor in the Mercer car is of the continental make in Model C, and Mercer make in the M "30."

2. The Stevens-Duryea was probably the first six-cylinder motor.

3. We do not discover a record such as you are in search of as made by the Correja car.

What Make of Rear Axle

Editor THE AUTOMOBILE:

[2,743]—Being a subscriber to your journal I take the liberty of asking with what make of rear axle is my car equipped. I have noticed that the same make is used on the Halladay, Auburn, Parry and former Overland Six. D. M. ERSKINE.

Ambia, Ind.

The Halladay car is equipped with a rear axle made by The A. I. Smith Company, Milwaukee, Wis.

Another Case of "Too Much Heat"

Editor THE AUTOMOBILE:

[2,744]—I have been having trouble with the engine on my Maxwell 30 and will appreciate it very much if you can enlighten me on the subject.

A few weeks ago I noticed that it heated up very easily and finally stopped running. On examination I found that the condenser (the car is fitted with a Splitdorf magneto and coil) had played out. I returned the condenser to the factory and had it repaired, but on placing it on the engine found that it heated up as badly as it did before. I then thought there was carbon in the cylinders and used a decarbonizer in them very freely, but it still heats up.

Arvonia, Va. E. E. ROBERTS.

If you are sure that the lubrication is sufficient and that the ignition system is now in proper order try reducing the supply of gasoline to the carbureter, the mixture perhaps being too rich.

Belt Dressing Has Been Used in the Past

Editor THE AUTOMOBILE:

[2,745]—I am a subscriber to your magazine and read everything carefully. I there-

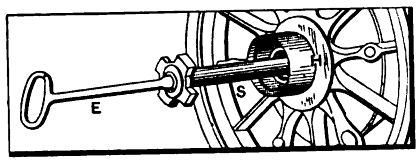

Fig. 3—Showing how the jackshafts can be withdrawn from a full floating axle and the style of tool used for the purpose

fore take the liberty of asking you for a little space in your columns, as I have never found anything about a friction drive. I wish to ask you whether there is any powder or other substance which can be put on the fiber wheel to prevent it from slipping when there is a hard pull at the start. I enclose herewith cut of the fiber wheel. Could this be changed to a shaft drive without incurring a very high expense?

WM. WIEMAR.

Belleville, Ill.

It might be a good idea to drill a lot of holes around the periphery of the disc and insert cork in these holes for the purpose of increasing the friction coefficient sufficiently to accomplish the desired end. It would be a simple matter to drill a series of $\frac{1}{2}$-inch holes around the periphery of the wheel, centering these holes from $\frac{3}{8}$ to $\frac{7}{8}$ of an inch apart, and the cork inserts might be $\frac{5}{8}$ inch in diameter, so that when they are compressed into the $\frac{1}{2}$-inch holes they will remain there, excepting that the surfaces will protrude out slightly, serving as the friction members. Still another plan that might be worth trying, since it is simple and inexpensive, is to take a piece of high-grade linoleum, reducing its thickness to perhaps 1/16 of an inch or slightly more, and fasten it to the periphery of the

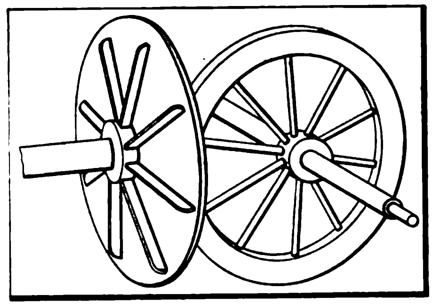

Fig. 4—Method of transmitting power from the flat disc to the fiber-covered friction wheel

wheel, using it as the friction member. It might be a little difficult to get this material to adhere to the wheel tenaciously for a long time, but it should be made to serve the purpose, unless you wish to go to the greater pains of using the cork inserts. Perhaps the National Brake & Clutch Company, of Boston, Mass., which concern deals in cork inserts, might be willing to suggest a method of using them under your conditions that will take you out of trouble. It would be a serious matter to undertake to rebuild the car with the idea uppermost of turning it into a shaft drive.

Brake Adjustments Made Easy

Editor THE AUTOMOBILE:

[2,746]—I noticed in recent issue of THE AUTOMOBILE on page 1121 that you described a good method of operating the brakes in the rear wheels. I have had this fitted to my car and it works very well and is a good equalizer. I live in a hilly district and have occasion to tighten the brakes frequently and will trespass on your space. Could you give me a sketch of a method of adjusting the brakes other than that shown in the illustration referred to? Something that can be done by hand if possible by lifting the floor boards. BERKSITE.

Reading, Pa.

No doubt you will find what you require if you will refer to Fig 5. In this illustration it will be seen that the brake lever arm is in the center of the chassis and the thumb nut on the end of the threaded rod is all that needs turning. The spring interposed between the arm and the locking nut holds the rod in place, prevents rattling and keeps a continual tension on the thumb nut, which would otherwise have to be fitted with a locking device.

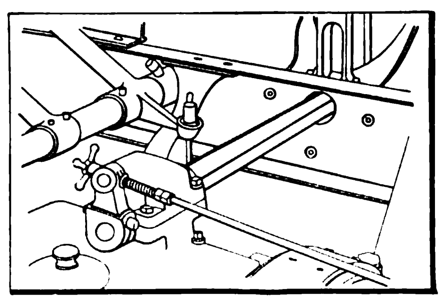

Fig. 5—Method of making a brake adjustment that can be easily tightened

Meeting Recurring Troubles

Presenting a Series of the Most Probable Cases

A series of correlated short stories, accompanied by diagrams and characteristic illustrations, including the nature of the troubles that are most likely to happen to automobiles, discussing their causes and effects, all for the purpose of arriving at a remedy. It is the aim, for the most part, to show how these troubles may be permanently remedied, and as a secondary enterprise it is indicated how the automobilist can make a temporary repair, thereby enabling him to defer the making of a permanent repair until a convenient time arrives.

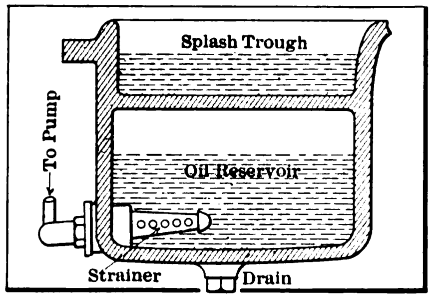

Fig. 3—Cunningham model H crankcase showing lead to pump

Lubrication of the Hupmobile Motors—The oil supply reservoir of the Hupmobile motor is located near the top of the right-hand side of the cylinders, the upper part of the tank and the cylinders being on the same level. The tank is filled through a filler hole on the top which is covered by a screw cap. There is a gauze screen in the filler opening so as to remove all foreign matter and prevent it from entering the tank.

In the tank box there are two needle valves which, when closed, prevent the oil from flowing from the reservoir. A spiral spring on each of these valves holds them down on their seats. The seats are beveled perpendicularly to the bevel on the valve stem and this, acting in conjunction with the pressure exerted by the spring, gives an oil-tight fit. The valves are lifted by an arrangement of rods and levers from the same rocker arm as the throttle. A projection on the throttle rod performs the office of a cam and is arranged so that the farther the throttle is opened, the higher the oil valves are lifted.

When the needle valves are opened the oil flows by gravity through the two oil leads which are located in the bottom of the oil tank. The oil leads take the oil to the crankcase which is divided into two parts by the central main bearing.

The oil fills the bottom of the crankcase on each side of the division in the center to such a height that the bottoms of the connecting rods will dip deep enough into the oil to form an adequate splash. So that the oil can not accumulate above the designed level, there is a stand pipe provided in each division of the crankcase, located between the front and rear pair of connecting rods respectively. Since the stand pipes are left open the oil, after it has reached the level of the top of them, will drain through. A drain cock, which, when running should be left closed, is situated under each stand pipe.

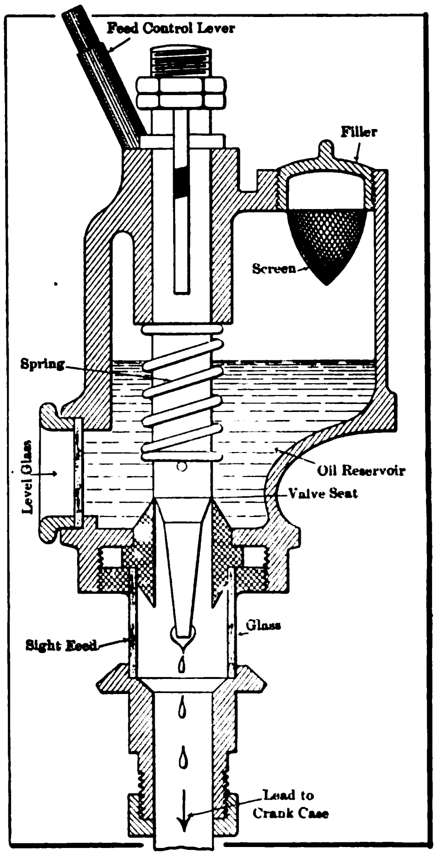

Fig. 1—Section showing the drop feed and oil tank on the Hupmobile

When the connecting rods dip into the oil, even if the car is running slowly, a heavy oil vapor will be generated which will pervade the entire crankcase and lubricate the cylinder walls, connecting rod bearings, cams, cam shaft bearings and the main bearings. After passing through the rear main bearing the oil flows into the gearcase and clutch housing and lubricates the moving parts therein. On the gearcase and clutch housing at the rear of the motor, there is a level cock and a drain plug in the bottom. The crankcase is also provided with drain plugs besides the stand pipe cocks already spoken of. There is a level glass in the reservoir-box at the rear end. Another point to note is that there is about one-sixteenth of an inch clearance on either side of the wrist pin to permit a free access of oil to this bearing.

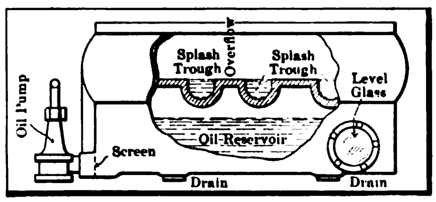

Fig. 2—Illustrating the oil reservoir and splash troughs on the Haynes car

The differentials, universal joints and rear axle housings are packed in grease. The rear axles are equipped with babbit bearings, to prevent the oil from leaking into the brakes.

Haynes Lubricating Scheme in Detail—The oil reservoir of the Haynes Model 20 car is located in the lower part of the crankcase. Its capacity is about one and one-half gallons. The oil is put into the tank through the breather pipe which contains a screen. The cover to the breather pipe is lifted off, thereby exposing the filler opening.

The oil is taken from the reservoir by an external gear pump which is driven off the camshaft by means of gearing. The pump is located at the rear end of the base on the right-hand side. There is a sight-feed located on the dash.

After leaving the sight-feed the oil flows down into the crankcase by means of a pipe which subdivides into two leads in the base of the motor. These two leads on the opposite sides of the motor are on the same level with one another and also on a level with a series of oil troughs which are placed inside the crankcase.

The connecting rods beat the oil in the troughs into a spray which lubricates the cylinder walls, connecting rod bearings, main bearings and the camshaft. After lubricating these bearings the oil will drain back to the troughs which are constantly being supplied with more oil by the two ducts on either side of the oil trough, one coming from each main lead from the pump. To take care of the overflow there is a drain hole between each pair of splash troughs. There are four of these splash troughs and two drains. As the oil overflows constantly there is always a stream of oil passing through the drains back into the reservoir, replenishing the supply here.

So as to allow the pump to get the last drop of oil that it is possible to give it the casting has been dropped a little at the rear end near the pump suction pipe, thus forming an oil pocket. There is a strainer placed in the pump suction lead which will ensure a clean supply of oil to the bearings. It is very important that this strainer should be kept clean and it is therefore advisable to remove and clean it occasionally.

The amount of oil in the tank may be readily determined by means of a four-inch gauge glass which is located on the front end of the crankcase on the right-hand side. A test cock at the correct level forms a sort of auxiliary gauge. The crankcase is also equipped with drain plugs.

Cunningham Cars Use Splash and Force-Feed—The Cunningham Model H car is lubricated by both the force feed and splash systems. The oil is carried in the lower part of the base or oil pan casting of the engine. This casting is made with a type of double bottom. The upper bottom carries a set of oil troughs for the splash system, while in the lower bottom the reserve supply of oil is carried.

The shape of this oil tank is merely a plain basin although it is somewhat deeper near the rear end.

The oil is picked up out of this tank by means of a gear pump. The pump is driven from the camshaft by means of spiral gears. The suction pipe leads down into the reservoir and at the end is supplied with a strainer. The oil is drawn up to the pump, from which it is driven both through the sight feed and the main oil lead. The amount passing through the sight feed bears a definite ratio to the total amount which circulates through the system; as the sight feed lead forms a sort of by-pass to the main lead. The proportion passing to the sight feed may be altered by means of a regulating valve on the sight feed lead at the rear of the motor on the left-hand side.

The rest of the oil from the pump goes to the main lead which consists of a hole drilled longitudinally through the entire length of the aluminum crankcase casting. At each main bearing a lead is drilled through the aluminum to the main lead, which is on one side of the casting, connecting this and the main bearing web. Another lead is then drilled down through the main bearing web into the casing, thus lubricating the main bearing. The oil then overflows out of both sides of the main bearing casing into the splash troughs.

The scoops on the bottom of each connecting rod pick the oil and churn it into a flying spray, which amply lubricates the cylinder walls and connecting rod bearings as well as the camshaft bearings. The wrist pin is hollow and open at both sides. When the oil in the splash troughs overflows it drains back by means of overflow holes into the oil reservoir, from where it is again picked up and passed through the system.

There is a brass level gauge on the left-hand side of the crankcase showing the amount of oil present in the reservoir; the total capacity of the reservoir being about three gallons. The filler hole is screened.

Other bearings on the car are equipped with grease cups while the transmission and differentials are packed in oil and grease.

Lubricating Pope-Hartford Engines—The lower half of the crankcase of the Pope-Hartford engine is cast so as to form an oil reservoir in the bottom. Above this reservoir there is a sort of tray carrying a series of troughs, one for each cylinder, which carry the oil for the splash system. The walls of these troughs are at such a height that if the oil is on a level with the top of the wall, the bottom of the connecting rod will dip deep enough to form an efficient splash. If the oil should overflow the walls it will pass into the bottom of the base casting.

The oil is drawn from the reservoir up into a mechanical oiler located on the side of the engine base. Before entering the mechanical force feed box the oil passes through a sight feed. From the box there is a series of tubes running to the various cylinders, each tube being provided with a small plunger pump. These pumps take the oil out of the box, through a sight-feed and, from there, to the walls of each cylinder. The oil, after having lubricated the cylinder walls, will drain back to the crankcase.

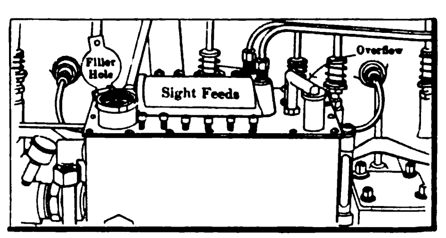

Fig. 4—Mechanical oiler of the Pope-Hartford car

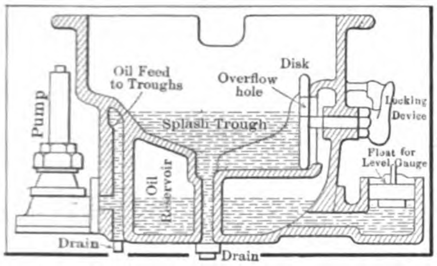

Fig. 5—Sectional view of the Pullman crankcase showing the oil channels and drains

The cylinder walls are also lubricated by the splash of the connecting rods into the oil troughs.

The mechanical oiler is driven by a shaft operated from the crankshaft. The shaft passes directly through the oiler driving not only that but also the water pump and magneto. Each lead in the mechanical oiler is equipped with a sight-feed located on the top of the oiler box so that it is easy to detect the location of any trouble in the system. A gauge glass is fitted on the dash showing the level of the oil in the force-feed box. When it is required to ascertain the amount of oil in the reservoir it can be done by means of two test cocks located on the side of the crankcase, the upper test cock being at the maximum permissible level, while the lower is at the minimum.

The oil is pumped up by means of the suction pipe from the crankcase much faster than it is used in the leads to the cylinder walls; hence there is always an overflow passing through an overflow pipe in the force feed box. This overflow pipe leads into the camshaft housing thus lubricating the cams, cam followers and the bearings connected with the camshaft. The excess oil drains through the overflow pipes and filter screens back into the reservoir. There is also a lead from the mechanical oiler to the gear case in the front of the engine. Otherwise these gears may be packed in grease. The other gears are oiled by splash from the crankcase.

The transmission and differentials run in oil and in their housings are located test cocks showing the level of the oil. Compression grease cups are located on the other bearings such as the clutch, universal joints, axle bearings, steering gear bearings and the oscillating spring bearings.

Pullman Cars Oiling System—Pullman cars are lubricated by the splash system. The crankcase is molded so as to have a double bottom. The inner bottom carries a set of splash troughs, one under each cylinder, which form the basis of the system of lubrication. Below this inner bottom is the oil reservoir, which takes in the whole lower part of the crankcase.

The reservoir is filled through an opening in the front left-hand crankcase supporting arm. The amount of oil present in the reservoir is determined by means of a level gauge glass located on the left-hand side of the motor between the two middle cylinders.

The rotary oil pump is located at the rear end of the crankcase on the left-hand side. It is driven off the camshaft by means of gears and a vertical shaft. This pump takes the oil from the rear end of the crankcase reservoir and sends it up into the splash troughs.

The connecting rods splash violently into the oil contained in these splash troughs at each revolution of the motor and beat the oil into a heavy vapor or mist which pervades the whole crankcase and amply lubricates the bearings contained therein.

The oil is continually being supplied to the motor much faster than it is being used and the overflow is taken care of by means of an overflow hole in a disk which is located in each splash chamber. This disk is able to rotate about its axis and in this manner raises or lowers the overflow hole which, of course, is not concentric with the disk. To keep the overflow level to its correct adjustment there is a locking device on the outside of the crankcase.

To prevent the oil from leaking past the end of the crankcase a centrifugal oil ring is hung on the end of the shaft. The oil is caught up by this ring as it drains toward the outside of

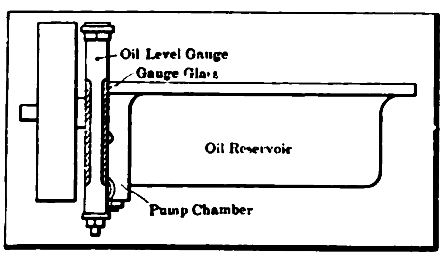

Fig. 6—The oil reservoir of the Mercer "30 M" showing level gauge and pump chamber

the crankcase and is thrown by centrifugal force off the ring to the sloping bottom of the crankcase down which it drains to the reservoir.

The oil may be drained from the splash troughs by means of drain pipes which take the oil from the bottom of the troughs and allow it to flow from the bottom of the crankcase. The reservoir itself is also equipped with drain plugs, both front and rear, so that it may be completely flushed out and cleaned.

There is also a drain under the passage through which the oil flows on its way from the pump to the splash troughs.

The other bearings all over the car are taken care of in the usual manner; and the differentials and transmission are packed in oil and grease.

Combination Oiling Scheme on Mercer "30"—The Mercer "30 M." is lubricated by a combination of the splash and force-feed systems, the force-feed part of the combination forming the primary method of lubrication.

About two gallons of oil are carried in the lower part of the base casting. This casting is divided so that while the lower part forms the oil carrying tank there is a moulded sort of tray in the upper part so that there is a series of oil troughs in it.

Openings in the tray permit the oil which overflows from the troughs to get back into the tank below. At the rear or flywheel end of the base there is a level gauge showing the amount of oil in the tank. This gauge is of the float type, a dial plate being placed horizontally on the end of the float tube. The float tube is carried high

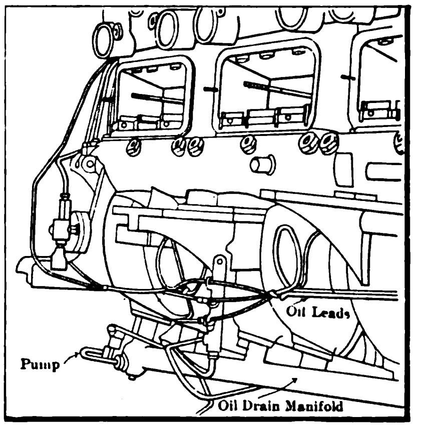

Fig. 7—Illustrating the Winton oil drainage system and the supply leads from the pump to the various bearings

enough so as to be visible when raising the right-hand part of the engine hood.

The oil tank is filled through the breather pipe which extends up very high from the top of the forward end of the crankcase on the right-hand side.

The force-feed system is operated by a Pedersen pump of the rotary type, located within the crankcase casting, which has a small pump chamber located on the rear right-hand side.

The stream of oil taken from the reservoir is sent through an upward lead, a sight feed on the dash, and then, to the main bearings of the crankshaft. The oil lubricates the bearings copiously and then runs out of both sides of the bearing casings where it is caught up by pockets of a cup-shaped form, which have an oil hole in the bottom. This oil hole registers with an opening in the crank, which is hollow, as is also the crank pin. The revolving cranks send the oil to the crank pins by centrifugal force.

A spray of oil is being constantly thrown off the connecting rods which serves to keep the crankcase filled with a mist of oil.

The splash troughs should be filled before starting on a trip and, with the oil draining constantly into them from the force-feed system they will be always overflowing no matter at what level the car is running.

The connecting rods dip into the troughs and splash the oil up into the cylinder, lubricating the walls, as well as the cams, cam followers, cam shaft bearings, timing gears and wrist pin.

The other bearings on the car are equipped with grease cups and oiling holes according to their positions. The transmission is placed in an oil tight case and runs in an oil bath.

Details of Winton Oiling System.—The Winton engine is oiled by both the splash and force-feed systems. The oil supply reservoir on the left-hand side of the motor is box-like in form and holds about eleven quarts. The oil reservoir is filled by means of a square opening in the top of the tank, the cover of which is removed by turning a round handle which projects from the top of the box. A gauze strainer is located just within the cover.

The oil is kept in circulation by twin pumps driven by the same eccentric off the crankshaft. The oil is pumped by one of these pumps to the top of the crankcase, from where it is led through direct leads to each main bearing. The crankshaft is drilled to provide an oil channel up into the crankpin, which is also drilled so as to provide an outlet for the oil into the connecting rod bearing, which is lubricated in this manner sufficiently to allow of an overflow of oil. This oil is thrown up into the cylinder and drains down into the splash troughs, which are molded directly in the bottom casting of the motor and are of sufficient depth to provide an oil well into which the connecting rod is allowed to dip, beating the oil into a spray. When the oil has reached the proper level in the splash troughs it is allowed to flow back to the rear of the engine base through a drain pipe. Here the oil is picked up by the twin plunger pump and delivered to the tank, where it flows through a vertical tube which stands perpendicularly in the tank and which is perforated near its top extremity. An umbrella-shaped baffle is placed over these perforations so that in case the cover is removed while the engine is in motion the oil will not spurt out of the tank.

The amount of oil supplied is regulated with a by-pass equipped with a throttle cock. When the latter is closed the entire oil flow passes through the system. When the cock is opened, however, there is a flow through the by-pass which takes the oil from the bottom through the pump into the top of the tank. If the cock is fully opened there will still be a small flow through the lubricating system, this being the minimum flow obtainable through the system

Splash System on the Maxwell I.—The Maxwell Model I is lubricated by the oil spray created by the splash of the connecting rods into the pools of oil which are held by the series of troughs placed below the respective cylinders. The oil supply is held in the bottom of the crankcase in these splash troughs and also in the supply tank, and is kept in a state of continual circulation. This circulation is kept up by means of a gear driven pump located on the left-hand side of the motor and operated by means of the cam shaft.

The course of the oil as it passes through the oiling system may be traced by following the pipe leads starting from the tank. The oil starts from the tank which is placed at a considerable height above the pump and therefore has a head sufficient to give the oil a ready flow. The lead from the tank to the pump is for the most part straight and leads directly into the suction port. From here the oil is forced up to the sight feed on the dash. After passing through the sight feed the oil will flow down into the crankcase to replenish the supply in the splash troughs and maintain it at the proper level. After attaining this level there will be a flow into the stand pipe placed at the proper height to catch the oil and lead it back again to the pump, from where it is passed up to the tank from which it started and is thoroughly strained before again passing through the system.

All the moving parts within the motor itself are lubricated by the splash.

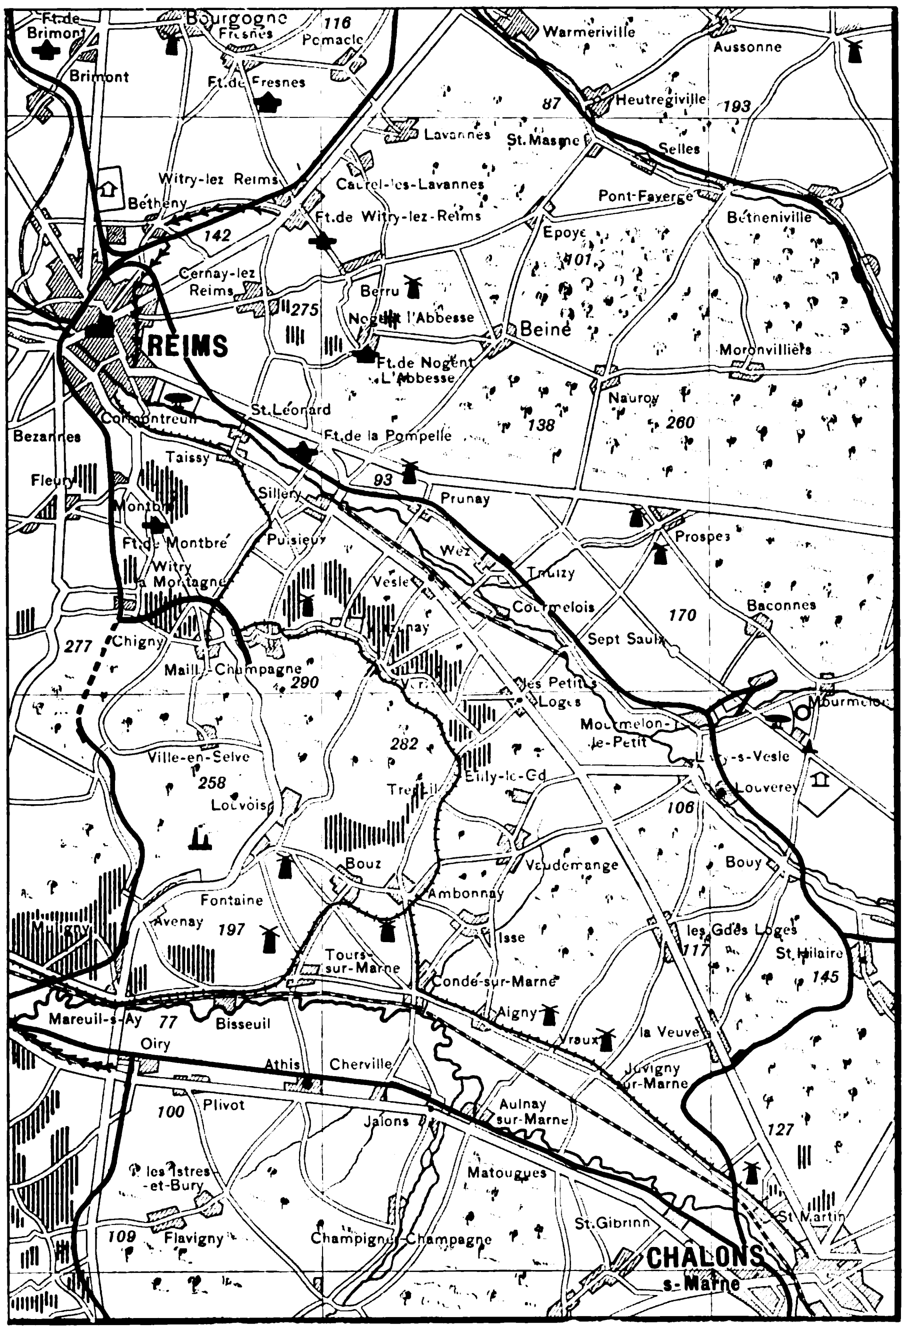
Making Maps for Air Travel

To Enable Aviators to Find Their Way Day or Night

The French Government, which has made the aeroplane an adjunct of the army, has just finished plotting the first of its charts designed specially for the guidance of aviators, and is actively at work on similar charts covering four thousand square miles of territory. A reproduction of the original map and an illustration showing the manner of its installation on the air machine are here given, intended to help to a proper understanding of the text.



A part of the Châlons sheet, showing the twenty-five miles between Châlons and Reims

AERIAL navigation has reached a stage of development in Europe, and especially in France, of which the average American, for all his intense and intelligent interest in this novel and fascinating form of locomotion, has little conception. On this side of the Atlantic opportunities of observing at first hand the capabilities of the aeroplane are still limited to infrequent and widely scattered exhibition flights and the small-scale experiments of the War Department. In Europe the aeroplane, as evidenced by the report a few days ago of the inauguration of taximeter-aeroplane service out of Lucerne, has become a staple of transportation. Aeroplane hangars are as common as automobile garages were in the United States a dozen years ago, hydrogen gas depots for the service of dirigible balloons are to be found in every considerable town, and aerial flights, except the very few especially remarkable for extreme length or extreme daring, such as the crossing of the English Channel, the Pyrenees or the Alps, arouse only the languid interest of the every-day spectacle.

In France the manufacture of aeroplanes has become an industry of large proportions. A year ago Blériot had already sold over two hundred and fifty machines, and Farman, Sommer, Antoinette and Voisin had booked orders for from twenty to fifty machines each. In the interval other manufacturers have entered the field, and the demand for aeroplanes has grown at a tremendous rate. All the manufacturers issue handsomely illustrated catalogues of standard sizes and types of stock machines. Each manufacturer has from one to three factories, and each his *école* for the instruction of intending purchasers and of professional aeronauts. For about 1000 francs one can learn to fly and obtain a pilot's license. A year ago these schools of flight had graduated over four hundred pupils. To-day their monthly output numbers scores.

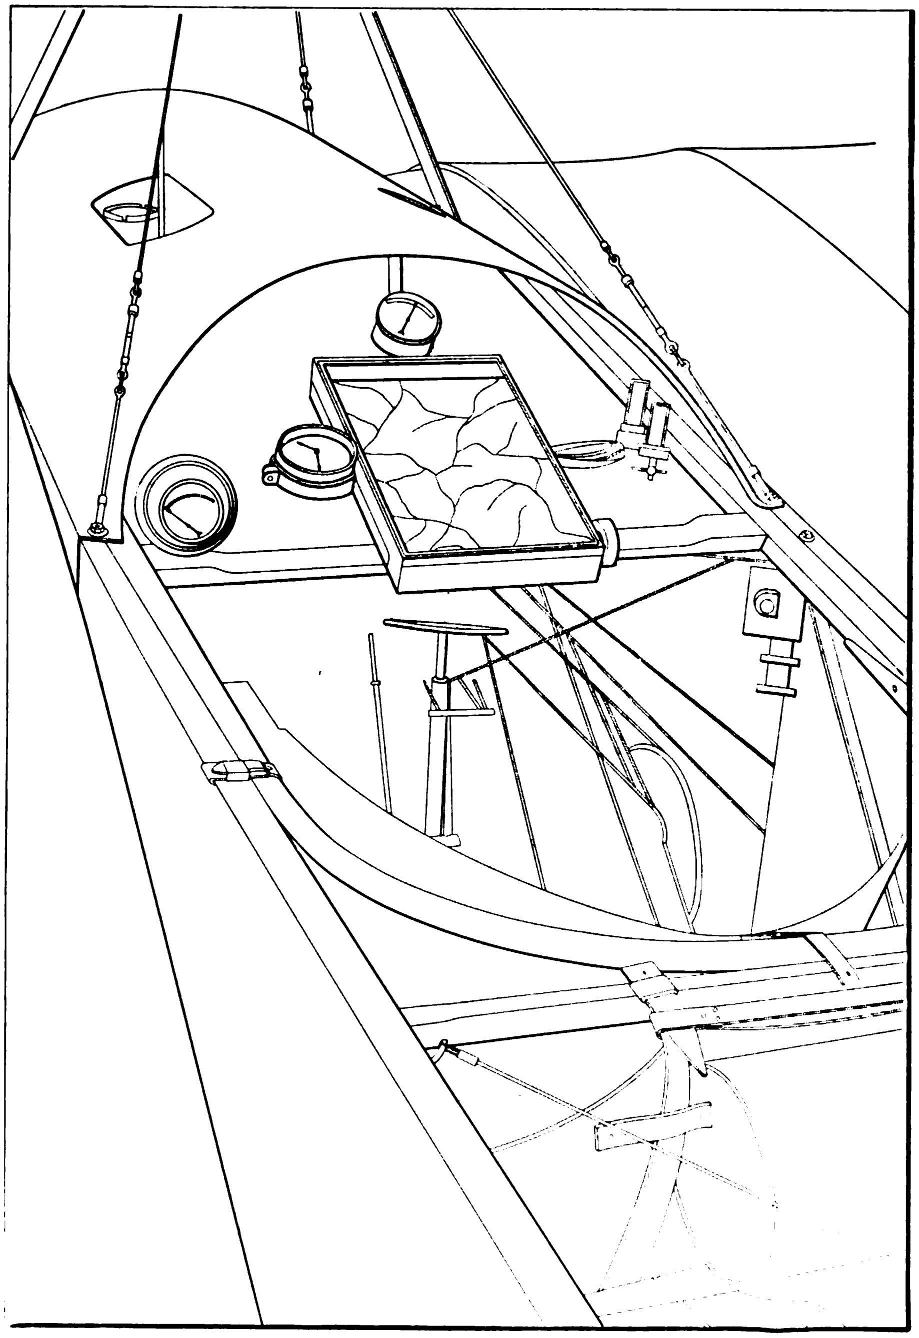
The actual piloting of aircraft over the short distances and at low altitudes attempted in the early days of aerial navigation was a matter of no difficulty. The pilot was always in sight of familiar landmarks and knew, in a general way at least, the character of every foot of the ground over which he flew. But as soon as cross-country flights became common pilots on "the high seas of the air," to quote a French army pilot, discovered that charts were an absolute necessity, and they were not long in making the further discovery that their requirements were very imperfectly met by the topographic maps of the ordinary character available to them. Hence there arose an increasingly insistent demand for charts especially designed to meet the needs of aerial navigators. The first step toward the complete charting of the country for aerial service has just been taken in the publication, by the Geographic Service of the French Army, of an aeronautic chart covering an area of nearly 4,000 square miles.

As a matter of fact, French air pilots had no choice but to await with what patience they could the initiative of the War Department. The Geographic Service of the Army is the only organization in the country with means at its disposal for rapid and efficient execution of work of this character. In spite of the urging of the sporting fraternity, and even of aeronautic experts within the Army, the War Department showed no interest in the matter until about two years ago and no inclination to carry out the project of recharting the country until after the grand Army maneuvers in Picardy in 1910. Aircraft were given a thorough trial in these maneuvers in military operations on a grand scale and conclusively demonstrated the immense possibilities of the aeroplane and dirigible in warfare. The War Department suddenly awoke to the value of special charts for aerial service, and, after a thorough inquiry into the requirements of air pilots, instructed the Geographic Service to prepare and publish, as an experimental sheet, an aeronautic chart of the district about Châlons.

The ideal set before the designers of the chart was to produce a map which should give the air pilot all the data necessary to enable him to set and hold a course at any time and under any atmospheric conditions, to avoid dangerous landings and to locate himself readily by the landmark indications on the chart at any point of the region covered by the sheet. The problem of largest importance was the determination of the proper scale and size of the printed sheet. It had to be small enough for convenient handling and at the same time cover a considerable area, so that when sheets are available for the whole country the pilot on long flights will not be unduly burdened with paper. Most important of all, the many data to be accommodated on the chart had to be disposed in such a manner as to be clear and legible at a glance.

The chart indications essential to aerial navigation are much more numerous than those of the ordinary topographic map. The aeronautic chart must show all roads, distinguishing the main highways from those of secondary importance, for the air pilot in flying over inhabited places or road intersections must be able to recognize the route leading to his projected destination. Double-track railways must be distinguished from single-track lines, since the latter are invisible from altitudes above 1,400 feet. Water surfaces, being visible from great distances and any altitude, are most important as landmarks, and all streams, lakes, and ponds must be clearly marked. Woods and forests also are extremely good landmarks, and the indication of clearings and of main forest roads is of importance. The charting of towns and villages must show their actual shape, the courses of all intersecting roads, and especially the exact location of the principal church steeples. In country districts, large buildings, windmills, isolated trees and cemeteries must be shown when they are salient features of the landscape; the smoke stacks of factories also are in many cases useful indications of direction. Fundamentally, of course, the aeronautic chart must be a topographic map and must show clearly the configuration of the ground, the valleys and gullies, the flat and sloping surfaces, isolated mounds and high bluffs. Altitudes must be given for every considerable elevation, not only to indicate their value as landmarks, but principally to show the pilot how high to fly. The mean declination of the compass must be indicated, to enable the pilot to fly during darkness and to regain his course when driven out of it by adverse conditions. Finally, the chart must show the location of all aviation parks, military parade grounds, hangars for aeroplanes and dirigibles and hydrogen gas depots and especially places where an attempt to land would be attended with great danger on account of the presence of vineyards, orchards, gardens, hop fields, ditches, hedges, quarries or electrical transmission lines.

In the Châlons sheet just published by the Geographic Service these diverse elements have been combined in a highly successful manner. In a reasonable space and without undue crowding they



The quarterdeck of a Blériot monoplane. In the center the chart holder; on the right, the compass; above, the barometer; on the left, the clock and the revolutions indicator have produced a chart which is really an adequate picture of the district covered by the sheet, legible at a glance and readily understood by a person having no previous experience with topographic maps. The scale chosen was that of the ordinary military maps of the French Army, 1 to 200,000, about three miles to one inch. The sheet measures 16 by 26 inches and covers an area of about 50 by 80 miles.

The chart is printed in six colors. The basic tint is buff, toned to represent the topography of the ground. Against this background the white of the roads and the blue of the water surfaces stand out clearly. Woods are indicated in tones of green, and towns, villages and dangerous landings in red. Black is used for railways, railway stations and figures of altitude. The actual profiles of important churches, steeples and towers are silhouetted in black. Conventional signs shown in the accompanying key, also printed in black, are used for smoke stacks, large buildings, windmills, isolated trees and other landmarks. Aviation parks and military parade grounds are printed in white over the buff and bear in red the conventional signs used for dirigible and aeroplane hangars and gas depots. The magnetic declination is printed in degrees on the margin.

The experience of the aeronautic experts of the military establishment at Châlons has shown this experimental sheet to be admirably suited to the purpose for which it was designed. Encouraged by its success, the War Department has ordered the charting of the quadrilateral Paris-Amiens-Givet-Bar le Duc, an area of over 9,000 square miles, which is to be the scene of the grand maneuvers during the present Summer. The indications for the use of air pilots incorporated in the Châlons sheet have been found useful in military operations on the ground.

Differential for Aerial Propellers

Granting that landing is that phase of aeroplaning which has caused the destruction of many a machine, the device here described is expected to prevent many accidents of this kind. The original appeared in Der Motorwagen.

IN landing after most aerial flights gliding is resorted to, the engine having been shut off for this purpose. Such a landing is always dangerous, at least in a certain measure, both for the machine and the operator, since preparations for landing are made at an altitude frequently so great that such obstructions as fences, inequalities of the ground, etc., are not always noticed. When the flying machine has come so close to the ground that these objects can be recognized distinctly the impossibility of a successful landing may be seen, in many cases, too late to restart the engine and rise to a greater altitude. This takes time, as two operations are necessary to attain the end, viz., the restarting of the motor and the adjustment of the elevating rudder. Furthermore, fractions of seconds are decisive at such times.

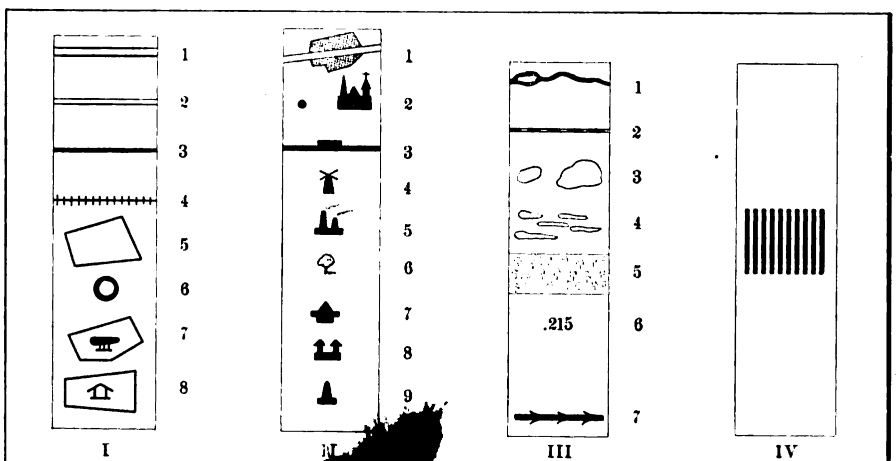
It happens even to skilled operators that the wheels or the chassis of the aeroplane come to grief in landing, and there is nothing surprising about such an occurrence, considering the high velocity with which the machines strike the ground. Braking the front wheels would in most cases result in overturning the machine owing to the inertia of the rear portions, while braking the rear wheels would probably be without any effect because of the small weight of the tail end of most machines. However, braking is desirable in aeroplaning for other reasons also, principal among which is the fact that there is seldom an abundance of landing ground.

But, since a great velocity is essential in making a gliding descent, the brake effect should be a sudden and strong one at the very moment when the front wheels touch the ground, or, better yet, when they are still about two or three feet above it.

To effect braking and also to make possible an easy upward start after gliding for some time, the German constructor, M. Bucherer, of Cologne, has built a differential brake for aeroplanes, the essential feature of which lies in the possibility of slowing down and eventually reversing the propeller at the right instant to enable the aviator to make a safe landing.

The inertia of the flyer naturally excludes the possibility of reversing the motion of the machine as a whole, the effect of which would be a disastrous one, and the only result of reversing the propeller is a very considerable reduction of its speed just before it is expected to land. If, however, a handicap should be espied at this instant the motor power could be utilized again to rise higher in the air.

In the illustration is seen the Bucherer aeroplane engine, which is of the rotary type, with air-cooled cylinders of 90 by 182 millimeters. The propeller is not mounted on the crankshaft, in accord with the general practice of the day, but a differential gearset connects crank and propeller shafts. The crankshaft carries a disc, on which two pivots are placed diametrically. These, in turn, carry the revolvable internal brake jaws.



THE CONVEN[illegible] INDICATIONS FOR USE OF AIR PILOTS

I [illegible] Main highways; 2, o[illegible]lways, single- or double-track; 4, narrow-gauge railways [illegible]ways; 5, aviation [illegible]g places; 6, hydrogen-gas depots; 7, dirigible hangars; [illegible] hangars

[illegible]nd vi[illegible] churches; 3, railway stations; 4, windmills; 5, smoke [illegible]tr[illegible] castles; 9, towers

[illegible] and ponds; 4, marshes; 5, woods; 6, altitudes; 7, elec-[illegible]

[illegible]eyards, orchards, gardens, hop yards, quarries, ditches

The internal and external brake jaws, which are located at the inner and outer surfaces of the brake housing respectively, are actuated alternately. The housing contains, in its front portion, a differential gearset, the small pinions of which are rotatably located on the two pivots of the axle cross. One of the two large differential wheels is a unit with the crankshaft and the other with the propeller shaft. The external brake is located at a point not shown in the illustration.

The operation of the differential is as follows:

1. If the external brake is loose the crankshaft turns from the left to the right. The internal brake is held in such a position that its jaws make the housing rotate by friction. The small pinions act as a clutch between the large wheels, and the propeller shaft is rotated in the same sense as the crankshaft.

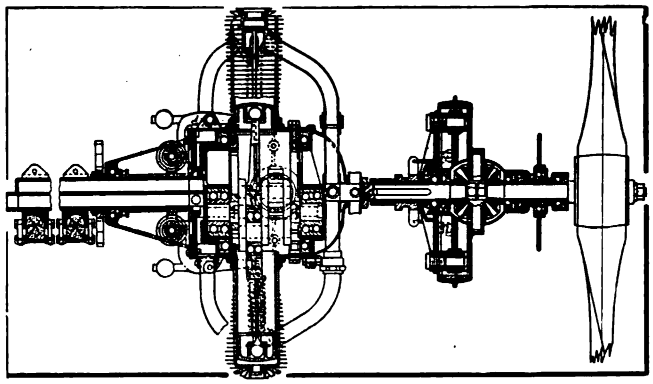
2. If both the external and internal brakes are loose the small pinions are driven by the one big differential wheel and work on the other wheel of the propeller shaft,

which latter does not now rotate. The brake housing rotates with the small pinions.

3. If the internal brake is loose and the external brake is fast in position, holding the brake housing in place so that it cannot revolve, the state of affairs is as follows: The crankshaft rotates as before, from left to right. The small pinions which are set on pivots in the now resting brake housing cannot revolve around the crankshaft and thus impart motion to the propeller shaft, which is made to rotate in the opposite direction to the crankshaft, from right to left.

If this machinery is utilized for landing it is possible to reverse the propeller instantly by braking the housing by means of the contracting-band brake without stalling the motor. At the same time the free-running number of revolutions of the engine falls to normal, and the motor then drives the propeller with full force in the direction opposite to that in which it was rotated before thus holding the aeroplane back.

The increase of weight and the addition of machinery to the aeroplane ought to be compensated for by the various great advantages of the installation of the differential set on the aeroplane.



Section of the Bucherer rotary aeroplane engine in which a differential is interposed between the engine crankshaft and the propeller shaft

As to Motion Study

The principle of intensive cultivation, as it is understood in an agricultural sense, must be applied to the production of automobiles, if the manufacturer hopes to make the most of his facilities.

INTENSIVE cultivation is the idea which dominates the activities of a burglar when he is prying open a vault, just as much as it is the idea that stands behind efficacious work in an agricultural sense. It is this same intensive cultivation that permits one maker of automobiles to turn out a large number of cars per annum under a given set of conditions and it is the absence of this condition that keeps another maker, although he may be endowed with the same facilities, from getting his quota of results. As a preliminary to intensive cultivation, motion studies will have to be indulged in, and the impression is harbored that too many builders of automobiles have substituted the brutality of the "accelerator" for the intelligent wiles of the master in motion study; but the time is not so far away when intelligence will have to sway the issue, even at the expense of being introduced in the person of the receiver. There is a superstition which has its foundation in the idea that co-operation is supplanting competition, but when the awakening comes the victims of lack of foresight will find to their sorrow that the master of motion study is the leader in the competitive department, and that his cleverness is two-fold, due to the fact that he not only points the way to more and better work per dollar of overhead, but he does it so silently that the neighboring maker who should be in a position to compete for success is fettered to his own stupidity.

Calendar of Coming Events

Handy List of Future Competitive Fixtures

Race Meets, Runs, Hill-Climbs, Etc.

July 5-22..........Winnipeg, Man., Fourth Canadian Competition for Agricultural Motors.
July 15............Philadelphia, Track Races, Belmont Park, Norristown Auto Club.
July 14............Philadelphia, Commercial Reliability Run, Quaker City Motor Club.
July 15............Guttenberg, N. J., Track Races.
July 15-17........St. Louis, Mo., Reliability Run, Missouri Automobile Assn.
July 17-19.........Cleveland, O., Three-Day Reliability Run of the Cleveland *News*.
July 17-22.........Milwaukee Reliability Run, Wisconsin State Automobile Association.
July 21-22.........Brighton Beach, N. Y., Twenty-four-Hour Race.
July 20-28.........Minneapolis Reliability Run, Minnesota State Automobile Association.
Aug. 1............Chicago, Ill., Commercial Reliability Run, Chicago *Evening American*.
Aug. 3-5...........Galveston, Tex., Beach Races, Galveston Automobile Club.
Aug. 12............Philadelphia, Reliability Run, Quaker City Motor Club.
Aug. 12...........Worcester, Mass., Hill Climb, Worcester Automobile Club.
Aug. 17............St. Louis, Mo., Reliability Run, Missouri Automobile Assn.
Aug. 25-26.........Elgin, Ill., Stock Chassis Road Race, Chicago Motor Club.
Sept. 1............Chicago, Ill., Commercial Reliability Run, Chicago Motor Club.
Sept. 1............Oklahoma, Reliability Run, *Daily Oklahoman*.
Sept. 2-4..........Brighton Beach, N. Y., Track Races.
Sept. 2-4..........Indianapolis Speedway, Track Races.
Sept. 4............Denver, Col., Track Races, Denver Motor Club.
Sept. 7-8..........Philadelphia, Track Races, Philadelphia Auto Trade Association.
Sept. 7-9..........Hamline, Minn., Track Races, Minnesota State Automobile Association.
Sept. 12-13........Grand Rapids, Mich., Track Races, Michigan State Auto Association.
Sept. 15...........Knoxville, Tenn., Track Races, Appalachian Exposition.
Sept. 16...........Syracuse, N. Y., Track Races, Automobile Club and Dealers.
Sept. ....Denver, Col., Track Races, Denver Motor Club.
Oct. 3-7...........Danbury, Conn., Track Races, Danbury Agricultural Society.
Oct. 7.............Philadelphia, Fairmount Park Road Race, Quaker City Motor Club.
Oct. 9-13..........Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 16-18.........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.
Oct. ....Atlanta, Ga., Track Races, Atlanta Automobile Assn.
Nov. 1.............Waco, Tex., Track Races, Waco Auto Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 7-10..........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9-11..........San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 10............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 28-30.........Savannah, Ga., Vanderbilt and Grand Prix Races, Savannah Automobile Club.
Nov. 30............Los Angeles, Cal., Track Races, Motordrome.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.

Foreign Fixtures

July 13-20.........Ostend, Belgium, Speed Trials.
July 21-24.........Boulogne-sur-Mer, Race Meet.
Aug. 6.............Mont Ventoux, France, Hill Climb.
Sept. 2-11.........Roubaix, France, Agricultural Motor Vehicle Show.
Sept. 9............Bologna, Italy, Grand Prix of Italy.
Sept. 10-20........Hungarian Small-Car Trials.
Sept. 16...........Russian Touring Car Competition, St. Petersburg to Sebastopol.
Sept. 17...........Semmering, Austria, Hill-Climb.
Sept. 17...........Start of the Annual Trials Under Auspices of *l'Auto*, France.
Oct. 1.............Gaillon, France, Hill-Climb.
Oct. 12-22.........Berlin, International Automobile Exhibition.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

INTEREST seems to be centered around the idea of silence of performance of automobiles. In the last few years the enthusiasm of salesmen was spent in the process of telling customers how silently their products performed. These salesmen were afflicted with a disorder that might have been called "hypnotic hearing." Despite the terrific din that some of their products made they could hear nothing in the shape of noise that seemed to be worth recounting to their "prospectives." It is almost uncanny that the silence of performance that they thought they had entrapped in their mechanisms is a reality to-day. The casting-out of the "noise devil" from automobiles is the surest indication the world has ever had of the fact that progress comes from promise and that anything man desires he can get if he goes after it.

* * *

EFFICIENCY is a much-abused word, meaning almost anything under the sun, and, at best, it is but a relative term. The efficiency of an automobile must ultimately be measured in terms of units of utility per dollar of cost, but it will take a fair display of ingenuity to describe a unit of utility. The best and the worst automobile might succeed in carrying five passengers a certain distance per day and continue to do the work for a term of years with the cost ranging neck and neck, or nearly so; but the worst automobile might ride its owner into an early grave or an insane hospital, or into poverty, whereas the best automobile should bring to its owner a heaping measure of well-being. The difference between the two may be measured in annoyance or the absence of it, and it is more than likely that the annoying type of automobile will beat a path to the tire man's store, the place where they "compound" gasoline, and to the garage repair-shop, whereas the car that holds within its maw the fullest measure of utility will show a fondness for the boulevard and a capability over the dirt road leading to the house of ozone over the hills and far away.

* * *

THERE is some evidence of a strained attempt to create sleeve types of motors as shown by some of the examples of these mechanisms as they appear in THE AUTOMOBILE this week, and goes to show that all the passengers in a "band-wagon" are not equally entitled to ride. Getting into the "band-wagon" is a very popular enterprise, but those who pay the piper will have to train their ears to distinguish between the tune of the music emitted by the fellow who occupies the front seat in comparison with the wail that characterizes the chap who jumps on as the wagon goes by. It is going to be a little difficult for the average purchaser of an automobile to arrive at a safe and sane conclusion of the difference between a good poppet valve type of motor and a bad job in the field of newer promise. It might be worth while to take a look at steam engineering for purposes of comparison, and a mental sojourn into the land of this old and stable art will lead the observer to the conclusion that the good examples of the various makes of steam engines are as prevalent to-day as they were a decade ago, but the users of steam engines seem to have the good sense to put a 40,000 horsepower quadruple expansion steam engine in an ocean greyhound, a 20,000 horsepower compound engine in a locomotive, a "simple" engine in an isolated plant, and a "safe" engine in an automobile. When the time comes to review the automobiles of the next ten years it is fair to say that the well-designed poppet valve type of motor will be represented by many good examples of them, the sleeve type of motor will have found its working level, the rotary valve will be a member of the congress of desirable mechanisms, and the piston valve will cast its shadow over a considerable zone of activity.

* * *

WHILE the struggle is going on to perfect motors, making them more simple and reliable to the entire elimination of noise, it will be the pleasure of most designers to discover that the disconcerting sounds to which automobilists take exception are largely in the chassis outside of the motor. There is every evidence of the ability of the worm drive co-operating with the silent chain to cure these noises. With silence of performance will come long life, and in the explanation of the reason for this desired condition account must be taken of the increased flexibility that is a natural attribute of a chain drive. Any mechanism that will prevent the load from coming on the members positively and quickly will save these members from the shock of instant loading, and a simple way to appreciate the good that will come from softening the blow lies in the mere statement that if the time of loading is increased to two seconds instead of one, the shock will be halved. There is every reason to believe that the designers of automobiles have turned their backs upon the "stable platform" so called, centering their interest in the conditions for flexibility as the most desirable characteristic in any automobile.

Automobile Board of Trade Active

Will Work for Good of Membership in Patent Matters

General Manager Bonnell, in an interview with THE AUTOMOBILE, *is authority for the statement that the newer organization, in taking the place of the old A. L. A. M., expects to work for the general good of the automobile industry, but that its plans are more or less passive, excepting that there is some activity in patent matters.*

THERE is some indication of pending patent litigation in the automobile industry. Certain companies holding patents are likely to start litigation, the idea being to impress possible infringers with a due respect for the rights of the owners of patents, as they are prone to claim, but it is the policy of the A. B. of T. to protect its membership from "exactions" on the part of those who may not be as conservative as the claims of their patent specifications might indicate to a man with a clear head and some legal lore. As for the patents that are in the possession of the board, or owned and controlled by the membership, it is the idea to protect the rights that belong thereunder. The board may also extend its domain in the realm of patents.

As a general proposition, according to General Manager Bonnell, it is not the purpose of the board to meddle with any matter that does not come properly before it. While there are a great many things going on all of the time in the automobile business, most of them are in the nature of activities that the respective companies are likely to be in a position to handle without the assistance of the Board of Trade, limiting the activity of the board to the questions that are too broad to be confined to the direction of a single company. As a broad assumption it may not be out of place to expect that the board work will depend upon the measure of benefit that is to be derived from an effort. If the benefit is to be confined to an individual company, that concern will be expected to do the work, but if the benefit promises to be general, it is then to be expected that the board wil! do the work and shoulder the cost of the effort. Mr. Bonnell states that the general trend of the automobile business is upward and that there is no cloud in sight such as would tingle the sensibilities of a pessimist.

Preparing for South's Big Road Convention

RICHMOND, VA., July 10—Preparations have just been completed by the American Association for Highway Improvement for the scouting tour of automobiles from Washington to Richmond, which is to pave the way for the big gathering of automobiles, as part of the Good Roads Congress to be held in Richmond, October 30 to November 1. Acting in conjunction with the Touring Club of America, the Highway Association has arranged for this scouting party, consisting of Paul D. Sargent, assistant director of the United States department of public roads; P. St. Julien Wilson, State Highway Commissioner of Virginia; F. H. Elliott, secretary of the Touring Club of America; J. E. Pennypacker, Jr., secretary for the American Association for Highway Improvements, and some of the Washington members of the Touring Club.

At least 500 automobiles will make the trip to Richmond in October to attend the convention of the American Association for Highway Improvements and the congress of its allied organizations.

The plans of the Highway Association and the Touring Club are to have all tourists from Northern, Western and Northwestern cities to gather in Washington, from which place they will move on to Richmond in an impressive procession. Automobilists from the South, of course, will come to Richmond.

The exposition feature of the convention is already attracting much attention among the manufacturers of road machinery and materials, and requests have been made for more than half the space in the building assigned for exhibits.

General Bingham Deserts Pavement Job

General Theodore A. Bingham, who made such a fuss as Commissioner of Police that it ended in a legal entanglement involving the Mayor of New York, will be remembered as having impressed Borough President McAneny with his peculiar ability to mend the wretched pavement that has long been an eyesore to everyone, and it comes as a shocking surprise to learn that Bingham has resigned his position as Chief Engineer of the Bureau of Highways, leaving behind him the impression that a few yards of red tape and other forms of official inertia were too much for him to overcome. Bingham, however, seems to think that the Bridge Department will give him something more in keeping with his ability. In the meantime the streets of New York are in a wretched state, and the citizens in general, not forgetting automobilists in particular, have every reason to believe that the whole situation might be mended were some capable man to take charge of the work, one in fine who might persuade himself to use a sharp knife on red tape and persuasion of an effective kind upon opposition.

Leland Succeeds Henderson as A. B. of T. Director

At the first quarterly meeting of the members of the Automobile Board of Trade, since its incorporation, which was held July 6 at its offices, No. 7 East 42d Street, New York, President Clifton announced that the new organization went into operation on July 1, and had taken over the A. L. A. M. offices.

A meeting of the Directors of the new organization was also held, and W. C. Leland, of the Cadillac Motor Car Company, was unanimously elected to fill the vacancy created by the resignation of Thomas Henderson, who has retired from business.

A number of important matters in connection with the new organization, such as patents and the forthcoming automobile show in New York, were discussed.

Motor Accessory Manufacturers' Board Meets

A meeting of the Board of Directors of the Motor and Accessory Manufacturers was held at the association's offices, 17 West 42nd Street, New York City, on July 7th, 1911. The following-named concerns were elected to membership: The Allen Auto Specialty Co., American Circular Loom Co., Champion Ignition Co., and the Detroit Carriage Co.

James H. Poster, of the Hydraulic Pressed Steel Company, Cleveland, Ohio, was elected a member of the Board of Directors to fill the unexpired term of the late Mr. W. S. Gorton. H. W. Chapin, of the Brown-Lipe-Chapin Company, Syracuse, N. Y., was made permanent treasurer of the association to fill the unexpired term of the late Mr. Gorton.

N. A. A. M. and M. & A. M. to Show at Palace

The most important action of the monthly meeting of the National Association of Automobile Manufacturers, Inc., held on Thursday, July 6th, was a decision to conduct an automobile show at the Grand Central Palace, New York, opening on January 10th and closing January 17th, 1912. This show will be open to all manufacturers, and it is known as the result of extensive correspondence carried on during the past month, that practically all of the manufacturers who do not exhibit at Madison Square Garden will take part. It is also practically settled that the Motor & Accessory Manufacturers will take the greater part of the space devoted to that branch of the industry which the association represents.

This show, it will be observed, will run during the last four days of the first week and first three days of the second week of the Garden show. It will embrace both passenger and commercial vehicles, each, of course, in separate departments. This arrangement is made possible by the splendid facilities offered by the new Grand Central Palace.

The building is located two blocks farther north than the old palace, is built entirely of stone and marble, except as to the floors, which are laid on concrete and fire-proofed, and affords 126,000 square feet of floor space.

The method of space allotment will be the same as that at the Chicago show. The executive committee referred all other details to the show committee and the general manager with full authority to proceed.

The Krit Motor Car Co., and Grabowsky Power Wagon Co., were elected to membership.

Favorable action on applications for reinstatement was taken in the cases of Vanderwater & Co., Ltd., Crawford Automobile Co., Warren Motor Car Co., and James Cunningham Son & Co., who took part in an unsanctioned show last winter and were therefore debarred from participation in sanctioned automobile shows.

C. G. Stoddard resigned as the representative of the Dayton Motor Car Co., and Alfred Reeves was elected as representative of that company and to fill the vacancy created on the executive committee.

The membership of Charles E. Duryea was transferred to the Duryea Auto Co., of Saginaw, Mich., and Harry S. Houpt was elected to represent the American Locomotive Co., in place of James Joyce, retired.

The members present at the meeting were: W. E. Metzger, Charles Clifton, Alfred Reeves, L. H. Kittredge, S. T. Davis, Jr., H. O. Smith, A. L. Pope, S. A. Miles, Thomas Henderson, J. W. Gilson, Benjamin Briscoe.

1912 Announcements Plentiful in Detroit

Detroit, July 10—The present month has been featured by a considerable number of factory announcements of 1912 lines, among the most recent of which are those of the Chalmers, Regal and Abbott-Detroit. In all these cases it is a notable fact that the makers have gotten farther and farther away from the old system of building but one chassis, which is equipped with a body variety as great as possible.

The Chalmers Co. will produce three chassis types—the "30," "40" and a new one of 36 horsepower. The last mentioned will be equipped with a self-starter and demountable rims. A four-speed transmission is also a feature.

The Regal Co. will continue its "30" and "40" as well as its underslung "20" roadster. It adds, however, an underslung "35" with a five-passenger body.

The Abbott Co. has supplemented its "30" with a "Model 44" seven-passenger type with a long-stroke motor, 4 1-2 by 5 1-2 inches.

Another company that is enlarging its line for 1912 is the Brush Runabout, which is adding the "Liberty-Brush"—a simpler type than the regular single-cylinder model which has proven so popular for runabout use.

The increased diversity in models is becoming a remarkable feature, as, in addition to those mentioned, the Metzger Motor Car Co. and the Packard have both announced 1912 "sixes" in addition to their regular lines. In fact, of the larger Detroit factories, the Ford, Warren and Cadillac are now about the only ones locally which still stick to one chassis type. None of these companies has made a 1912 announcement as yet. The E-M-F Company branch of the Studebaker corporation really deserves ranking as a fourth in this group, as its two chassis types are put out at separate plants and by separate manufacturing organizations.

Bergdoll to Head A. M. A. A. Show Committee

The Executive Committee of the Automobile Manufacturers' Association of America which is composed of many of the leading independent makers who are not identified with the new Automobile Board of Trade, held a meeeting at their headquarters in the Night and Day Bank Building, corner of Fifth Avenue and 44th Street, on Friday afternoon, when plans for their annual Automobile Show, which will be held in the new Grand Central Palace during the week of January 1, were discussed.

After the meeting it was announced that arrangements had been concluded with the Aeronautical Manufacturers' Association, setting aside the entire third floor of the Grand Central Palace for the exhibition and display of the latest types of aeroplanes with their motors and accessories.

At the conclusion of the meeting it was announced that Louis J. Bergdoll, head of the Bergdoll Motor Company of Philadelphia, had been appointed chairman of the Show Committee and that the other members of the committee would be appointed later.

Convenient T. C. A. Maps for Motorists

Eight new map sections covering the most popular touring districts of America and which have been compiled under the auspices of the Touring Club of America, are now being distributed among members of the club and other motorists. These maps include in their respective sections, New England, showing all the popular touring routes through Massachusetts, Connecticut, Vermont, New Hampshire and Rhode Island; Maine, with the best routes to Canada; New York with a section of Canada; New Jersey and Pennsylvania, the Middle West, Southeastern part of the country and the Southern States. The maps are compiled on a scale of two miles to the inch and are very legible, mounted on linen, while the mileage distances between various towns and cities situated along the main routes are clearly defined.

Premier Transcontinentalists' Progress

Chicago, July 8—The ocean-to-ocean tourists reached Chicago Thursday and passed Friday here. To-day they headed west again intent on making Davenport, Ia., by night. In the party are thirty-eight enthusiastic motorists, eight of whom are women, who are riding in a dozen Premier cars, while accompanying them are a motor truck for carrying the surplus baggage and a service car. Preceding them and blazing the trail is Ray McNamara, who knows every foot of the road from one coast to the other.

Miles Spending Dog Days in Maine

S. A. Miles, general manager of the National Association of Automobile Manufacturers, is invading Christmas Cove, Maine, where he will spend nearly all of his time until the end of October. Arrangements have been completed for the show at the Grand Central Palace in New York this year, which undertaking adds materially to the activities of General Manager Miles.

Five Perfect Scores in Missouri A. A. Run

St. Louis, July 10—Five touring cars finished with perfect scores in the July 4 reliability run of the Missouri Automobile Association. The contestants made unusually good time over the 34.7 miles course. There were two divisions, one for pleasure cars and the other for trucks.

The pleasure car score was:

Car	Driver	Score
Kline	Ashley Gray	Perfect
Selden	H. B. Beguelin	Perfect
Cadillac	Dan Wandell	Perfect
Case	E. L. Colwin	Perfect
Mercer	Charles Kean	Perfect
Firestone-Columbus	John Burns	991
Regal	Roy Anselm	991
Ohio	George Bolz	991
Mercer	R. W. Russell	989
Regal		976
Paige-Detroit	H. M. Paine	949
Ohio	George Mueller	Disqualified
Halladay	Robert Adams	Disqualified
Marion	R. W. Pissell	Disqualified

The score of the trucks was:

Car	Driver	Score
Atterbury	I. C. Summers	Perfect
Federal	R. Stellgis	Perfect
Atterbury	A. Fidler	993
Lambert	D. Perrin	984
Utility	T. H. Goddard	Perfect
Waverly	W. Koch	996
Atterbury	A. H. Elliott	Disqualified

Vice-President Henderson Honored

Thomas Henderson, of the Winton Motor Carriage Co., who has for many years been prominently identified with the work of the automobile trade associations, has decided to retire from active business life. He has already resigned his position on the executive committee of the Association of Licensed Automobile Manufacturers and will, on the first Wednesday of September, retire from the executive committee of which he has been a member for ten years.

On Thursday evening, July 6, twenty-five men in the trade, with whom Mr. Henderson has been prominently identified, held a dinner at the Engineers' Club in New York in his honor, and presented to him a loving cup and an address engrossed on vellum and beautifully bound. The gentlemen present, in addition to Mr. Henderson, were S. T. Davis, Jr., William R. Innis, W. T. White, A. L. Pope, Alfred Reeves, Charles Clifton, W. E. Metzger, S. D. Waldon, George Pope, R. D. Chapin, H. O. Smith, E. E. Bartlett, H. B. Joy, L. H. Kittredge, C. C. Hildebrand, Hugh Chalmers, J. W. Gilson, C. C. Hanch, S. A. Miles, Benjamin Briscoe, M. J. Budlong, R. D. Garden, Wm. Mitchell Lewis, W. C. Leland, Frank Briscoe.

The decorations, in recognition of Mr. Henderson's nationality, were largely of Scotch plaids, thistle and heather. Mr. Henderson, who, until the last moment, had no inkling of the event, was met on his arrival at the club by a Scotch piper in full regalia. The music of the evening also consisted largely of Scotch airs.

The address was presented by Mr. W. E. Metzger, president of the National Association of Automobile Manufacturers, Inc., and the cup by Mr. Charles Clifton, president of the Association of Licensed Automobile Manufacturers. Both gentlemen spoke earnestly and feelingly of the esteem in which Mr. Henderson is held by every one with whom he is acquainted and so did Colonel George Pope and others who followed. Mr. Henderson's response was a masterpiece, declared by every one present to be the finest thing of the kind to which it had ever been their good fortune to listen.

Stutz Busy Producing Racing Duplicates

Indianapolis, July 10—The first car built under the direction of Harry C. Stutz performed so encouragingly in the 500-mile International Sweepstakes at Indianapolis on Decoration Day, that the Ideal Motor Car Company of Indianapolis has instructed designer Stutz to duplicate this model as a manufacturing proposition. The Ideal Motor Car Company has a well-appointed building, three stories high, which was recently erected on Capitol Avenue by Carl G. Fisher. The new organization in addition to designer Stutz includes W. D. Myers as sales manager, and work has so far progressed in the new plant that deliveries are being promised for August 1, offering to purchasers three types of bodies including a roadster, a four-passenger and a five-passenger fore-door type of touring cars. Agencies are being booked, and the indications are that Indianapolis is to be the home of another very active company devoted to the building of automobiles.

Dead Horse Climb Arrangements Completed

The Dead Horse Hill Climb Committee consists of John P. Coghlin, chairman; J. W. Harrington, Daniel F. Gay, Chester E. Green, and Frederick S. Clark.

A. D. Converse, president of the Massachusetts State Automobile Association, will be referee; Wagner will do the starting.

Contracts have been placed for repairing the hill, which is somewhat down at the heels due to a season of excessively dry weather. In fixing the hill it will be packed with binder such as calcium chloride or Tarvia. Considerable interest is being aroused in this event, and a large number of entries are expected. Among the events scheduled there will be one in Class "A." An amateur event is scheduled for the Worcester County Championship, and another amateur event for gasoline cars only is listed. In Class "B," which is open to any chassis of gasoline cars that conforms to the "stock chassis" rules will be run off. Class "C" will also have its representation open to any gasoline car or chassis under the rules of the Contest Board. A free-for-all event is expected to arouse interest, and there will be two exhibition events, closing the day of sport with motor-cycle racing.

Willys and Garford Make a Trade Arrangement

It was erroneously reported in some of the trade papers last week that John N. Willys and Arthur L. Garford had joined hands, thus lending the impression that there was a combination of the Overland and Garford plants. George W. Bennett, executive head of the Willys-Overland plant, is authority for the statement that Mr. Garford holds no stock in the Willys Garford Sales Company. The new concern will market Garford trucks.

Racing Put in Disrepute by Advertising

Editor The Automobile:

In the Rayfield Carbureter advertisement of June 22, statement was made: "The 1912 model stock Lozier car, using a stock Rayfield carbureter, finished second, 32 minues behind the Marmon, having 11 tire changes against 4 tire changes made by the winning car."

This was evidently a clear case of hastily-prepared copy, since the Lozier car finishing second was 32 seconds behind the Marmon. Reader.

Vale, Lowell; Redivivus, Riverhead

With the announcement that the road race tentatively scheduled for the Lowell, Mass., course for September 23 had been definitely abandoned comes news that an effort is now making to promote a long-distance stock car contest over the Riverhead course. It is the idea of the promoters to stage the event for a Saturday late in September.

Schaeffers to Make Foreign Tour

Joseph Schaeffers, M. E., member of the S. A. E., is now taking an extensive European trip, during which he will visit England, Germany, Belgium and Austria to observe the progress that has been made in rotary valve and sleeve motors on the other side. He will return in seven weeks.

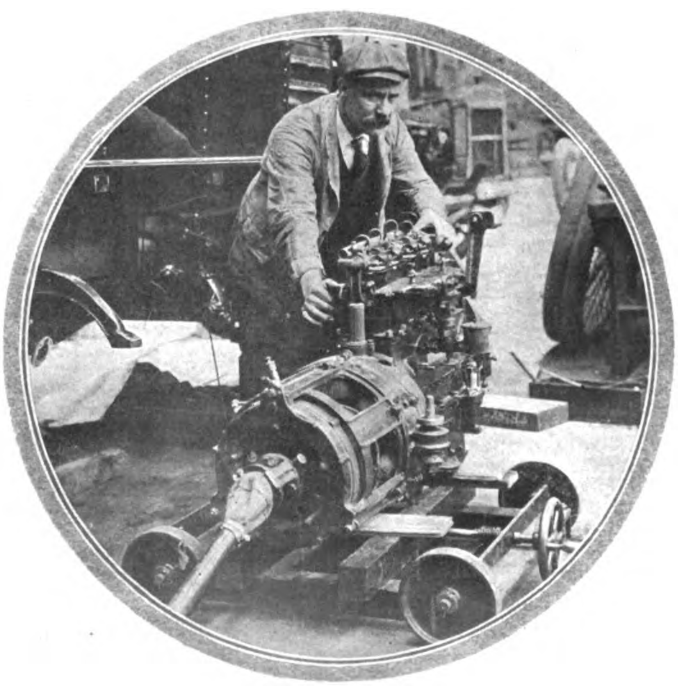
British Makers Looking for New Field

Passenger Automobile Business Falling Off

According to the latest advices from Coventry, Eng., the British makers of automobiles are in the grasp of sharp competition from the passenger automobile point of view and some of the more important of the companies are branching out. The story, as it is here related, tells how the newer activity is aimed to reach out, invading foreign countries, making the farmers of other lands pay tribute to British acumen.

A NEW phase of development has now been entered upon by the British automobile industry. The pleasure car business, which has for so many years been the sole support of the leading firms, is by no means the profitable undertaking which it was formerly. There is still, and always will be, a very large demand for touring and pleasure cars, but the gradual drop in power and price—till now the most popular vehicle is the 15-horsepower car at $1,800—has reduced the manufacturers' profits to a level which is actually serious in its outloook. With this fact before them, the most prominent firms have for some time past been casting around for new lines of profitable business, and passing by the aviation section as useless for yet some time to come, the majority have settled upon the commercial vehicle as the most promising field for future enterprise. As is generally known, the utility motor section has already been well developed in Great Britain, but, so far, a few comparatively small concerns have had the market to themselves, and their limited resources and output have been unable to make full use of the available demand.

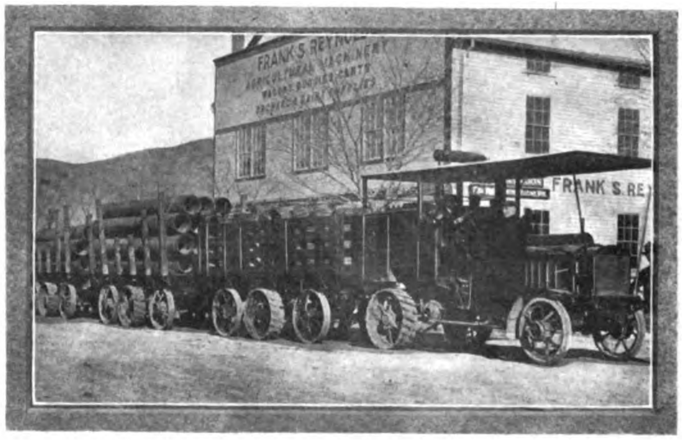
One automobile firm to come forward with its fully matured plans is the Daimler Company. This firm, now amalgamated with the Birmingham Small Arms Company, employs over 5,000 men at its two Coventry works. In the present case, the latest designs of commercial vehicle, to be exhibited at the forthcoming Royal Agricultural Show at Norwich, have attracted general attention throughout the trade.



Power unit for a long train of luggers

The chief sections of the Daimler commercial vehicle department comprise the omnibus, the agricultural tractor, and the road train for goods transport. Smaller goods lurries—up to 5 tons capacity—are likely to make their appearance in the near future, but at present the actual productions are as stated.

The Daimler motor 'bus has been on the road in its experimental state for over two years. In its final approved form, it has passed the searching tests imposed by the London Police Authorities (the new regulations for 1912 being in every way more exacting than before) and the appearance of a fleet of 200 of these vehicles on the London streets is definitely planned for the coming fall. The Premier Omnibus Company, a new $5,000,000 concern, will look after the operation and control.



Daimler road-train ready to "pull out"

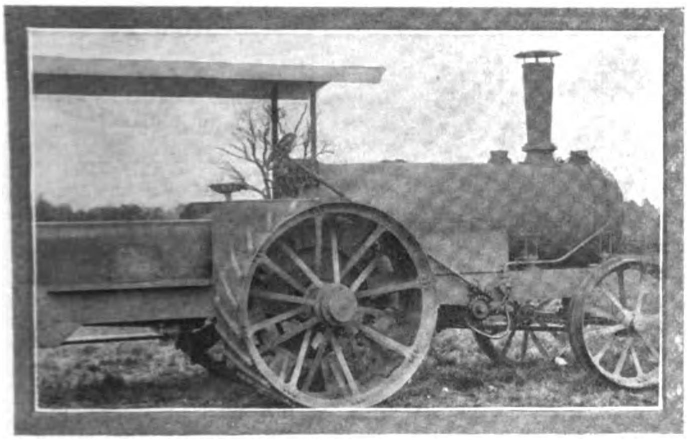
On the constructional side, the Daimler 'bus is a radical departure from all previous types. The frame consists of two long pressed-steel girders, joined together by a sheet steel member which also forms the foot-well for the interior body. From the two side members are suspended the duplicate power plants, each consisting of a 15-horsepower Knight motor, a dynamotor, clutch, propeller shaft and worm-driven live axle—this last not extending across the vehicle, but driving its own wheel only. For the equalization of the two propelling units, a buffer battery of some 24 cells is placed at the forward end of the chassis, beneath the driver's seat. By means of an ingenious, yet comparatively simple electrical control, the dynamotors alternately charge up, or take current from, the battery as occasion demands, and all that the driver has to do is to steer the vehicle and to move a single speed-control lever on top of the wheel. When running on the level with full load (36 passengers) the engines are developing about half-power, and the surplus energy is automatically used to charge up the battery till this is at full voltage. Then a solenoid automatically closes the throttles till the power of the engine is just sufficient to drive the bus along at the required speed. As soon as a hill is reached, the solenoid opens the throttles gradually, and, finally, if the grade is too steep for the engines themselves to take the vehicle up at full speed, the battery commences to supply current to the dynamotors, and in this way the requisite extra power is obtained. From the driver's point of view, the control is simplicity itself, for much less exertion is required than in the case of operating a pleasure car.

Not the least interesting feature of construction is the manner in which a power unit can be removed and replaced by a stand-by set, the whole job being easily effected inside half an hour. The illustrations will show how neat and compact is the general design of the bus, which weighs, complete and ready for running, only 3 tons 8 cwt.

With regard to the new agricultural tractors, these are made in two types—the 100-horsepower, and 30-horsepower. The former is intended for use in such places as Canada, Russia and Argentina, where long plowing runs are required. A 21-disc plow, going down to a depth of 9 inches, can easily be hauled by this big tractor and in addition, the usual range of portable and stationary machine work, in addition to road haulage, is provided for.

How the Plan Is Worked Out

The engine is a 100-horsepower 6-cylinder Knight type, running on either gasoline or kerosene at the option of the buyer. Only magneto ignition is provided, on account of the many drawbacks of storage cells in new country; and for starting



How the 100-horsepower tractor looks

purposes a small "pup" engine, one cylinder, air-cooled, is fitted, driving the main shaft behind the flywheel and disconnected when out of use. The main engine is placed right at the rear of the machine, in an easily accessible position. The transmission comprises metal-to-metal clutch, two speed and reverse gearbox, and then worm drive of the countershaft. By this worm drive, using a steel worm and a phosphor bronze worm wheel, a large gearing reduction is easily obtained, with good efficiency. Final drive is by spur gears on the countershaft, which mesh with large gear rings on the main wheels. The total gear reduction is 114 to 1. Roller bearings are used throughout. The direct drive, for ploughing, gives a speed of 2.4 miles per hour, while the indirect hauling speed gives 4 miles per hour.

A large circular fuel tank forms the front of the machine, while behind the funnel comes the radiator. A fan impels air through the latter and, in addition, the engine exhaust is discharged through an injector nozzle up the chimney in such a way that a good air current is induced through the radiator tubes. The water consumption on full load is less than a gallon a day, while the fuel capacity is sufficient for a 12 hours run. The total weight is 11 tons and a draw bar pull of over 12,500 lbs. is given.

The 30-horsepower Daimler tractor has a 4-cylinder Knight engine of 4 inches bore, 5 1-8 stroke, giving its rated power at 1,000 revolutions per minute. In this case, the engine is placed in front beneath the bonnet, and, behind, comes the clutch, three speed gearbox and worm driven countershaft. The direct ploughing speed is 2 1-2 miles an hour; the other speeds give 4 and 7 miles respectively. A wagon body, of two tons capacity, is provided and a tipping gear operates this when required. This smaller tractor is intended for home use and also for countries like Australia, where comparatively small farms are the rule.

Concerning the road-trains, the third branch of Daimler activity, these were formerly known as the Renard. The Daimler road-trains are in use in Australia, India and elsewhere. California and British Columbia being exploited. The principle of the train is, of course, that the locomotor, in front, does not do any hauling, but just carries the motor which supplies power to a long flexibly-jointed shaft which runs the whole length of the train—usually four wagons or followers being employed. Each follower, by means of a worm-driven gearbox and final claim transmission, drives itself. Each follower is steered by the movement of the vehicle in front. All that the driver has to do is to steer his "loco" in the touring car way, and then, as each wagon reaches the place where the "loco" has left the straight line, it will begin to turn, and then pass on the movement to the next follower. A train of five vehicles can thus be steered over a plank ridge or along a chalk line, without any trouble. This means, of course, that the driver can easily avoid all the bad places on the road. Each wagon can carry 6 to 8 tons and as this load is divided over the six wheels, the maximum axle load is comparatively small. The motor used, it may be noted, is an 80-horsepower 6-cylinder Knight of 4 7-8 by 5 1-8 inches.

Wisconsin State Fair Meet Abandoned

MILWAUKEE, WIS., July 10—In line with the general movement to stop racing on mile horse tracks in the United States, the Wisconsin State Board of Agriculture has decided to abandon the idea of holding a race meet on the last day of the Wisconsin State fair in Milwaukee on Sept. 16. It is probable that the Board of Agriculture will not again sanction racing meets on the track. The idea of holding a motor show in conjunction with the State fair will be carried out as originally planned.

Warner Mfg. Co. New Plant Finished

TOLEDO, O., July 10—The new plant of the Warner Mfg. Co. here, is nearing completion and the company will have occupancy about July 15. This will more than double their present capacity in sliding gear transmissions, steering gears, differential gears and control sets.

Example of 30-horsepower tractor

Seen in the Show Window

AMONG power pumps used for inflating automobile tires the Rector tire inflator (AQ) is to be mentioned. It consists of a small pump, the plunger of which is reciprocated in its cylinders, utilizing for this purpose the power of the engine of the car itself. The manner of operation is clearly seen in the illustration, in that the pump is actuated by a split gear drive, one pinion being permanently attached to a halftime shaft of the engine, *i. e.*, pump or magneto shaft, while the other is integral with the air pump and if held against its mate on the halftime shaft, serves to impart reciprocating motion to the plunger of the inflator. The pump is made by the Rector Engineering Company, Metropolitan Building, New York.

ACETYLENE, in most cases, is bought and transporated in tanks under a pressure which sometimes reaches two hundred pounds. Naturally, as the supply is drawn upon, this gas pressure falls off, and it would be fair to expect that as the original pressure of the gas current is diminished, the flow and consequently the height and illuminating power of the flame fall off too. On the other hand, the pressure while the tank is full, or nearly so, is much higher than would be necessary to produce a flame of proper height and strength. To solve the problem of furnishing an unaltered amount of acetylene under the same pressure at all times, a regulating device has been placed on the market. This is the Simplex gas regulating valve (AR) made by the Champion Igniter Company, 585 Boylston street, Boston, Mass. The adjustment of the regulator is accomplished by turning the revolvable piece of the device to one side or the other, thereby opening or closing an orifice to a varying degree, automatic regulation being a further consequence of this operation.

VAPORIZING the less volatile constituents of engine fuel is a complicated task, but in the construction of the Universal hydrocarbon gas producer its makers claim to have made a step toward the final solution of the problem. The device mentioned (AS) is 5 inches in diameter, its length varying in proportion to the power of the engine to which it is applied. In the producer the fuel is first atomized, and then drawn by engine suction through pipes heated by the exhaust gases, so that a complete vaporization of the liquid parts is effected. A very high fuel efficiency is claimed for the device by the Universal Oil Converter Company, 227 Borden avenue, Long Island City, N. Y.

AV—Adlake lamp for illuminating rear license number

WELL-LUBRICATED cylinders represent a desirable condition in an engine, and since the safest way of gaining one's end is by applying force, this principle has proved to work out well in the case of gasoline engines, where force-feed systems were used to introduce into the cylinders the oil necessary to insure smooth running. One of the well-known mechanical systems is here shown, this being the Detroit oiler (AT). Like most force-feed systems it is worked in connection with a circulating pump, the oil from the reservoir being forced through the mechanical oiler box seen in the illustration, whence it flows through individual leads to cylinders and bearings supplying all of them with the proper amount of lubricant. The type of oiler here shown, in several sizes to fit the various sizes of engines, is sold by the makers, the Detroit Lubricator Company, Detroit, Mich.

EYES, like eyeglasses and telescopes, are valuable instruments and deserve to be cared for and protected against dust and rough mechanical influences in at least the same measure as the artificial devices named above. At the same time the use of eyes cannot be dispensed with and the protecting case must be so made as not to interfere with the sight of the owner of the eyes. Another point to be carried in mind is that to be in proper working condition the human eye requires a certain amount of ventilation, all of which must be considered in the construction of good automobile goggles. The Cover rubber goggles (AU) are made of soft rubber and perfectly transparent material so as not to handicap the correct functioning of the eye in any way; the breathing feature is also incorporated in this device by means of air holes placed in the rubber in advantageous locations. These goggles are handled by Sussfeld, Lorsch & Company, 37 Maiden Lane. New York.

CONFORMING with the laws in most States, the automobilist is required to illuminate at night the number on his rear tag, and for this purpose the Adlake license number illuminator shown at (AV) it well adapted. It consists of a full-length reflector, sliding bottom glass and red jewel. One end shows white light, while the other serves to house the electric connection. Heavy brass is the material used in the manufacture of this lamp, and it may be of interest to know that any desired finish is supplied by the makers, the Adams & Westlake Company, of 319 West Ontario street, Chicago, Ill.

VOL. XXV NEW YORK—THURSDAY, JULY 20, 1911—CHICAGO No. 3

THE AUTOMOBILE

Owners Awakening to Body Needs

A Place for Apparel Is in Brisk Demand

Sentiments voiced by many readers of THE AUTOMOBILE *are distinctly in favor of definite lines of thought founded upon the necessity of providing certain conveniences that are not found in bodies for automobiles. It seems to be true also that the tires and tools, not forgetting the battery, should be placed inside of the car, and it is the purpose here to show that automobiles may be so designed that there will be a place for everything, even the chauffeur.*

mention would have to be made of the fact that bodies as they were applied to automobiles were lacking in many respects from the point of view of the newer service, and it is to the ingenuity of owners of automobiles that we may trace the practice of loading down the running boards, and the placing of needed facilities at convenient spots over the exterior surfaces of the bodies of automobiles.

In the carriage-makers' time the coachman and the footman had their own domain, and they were provided for according to their needs, and in keeping with a certain ethical situation. When

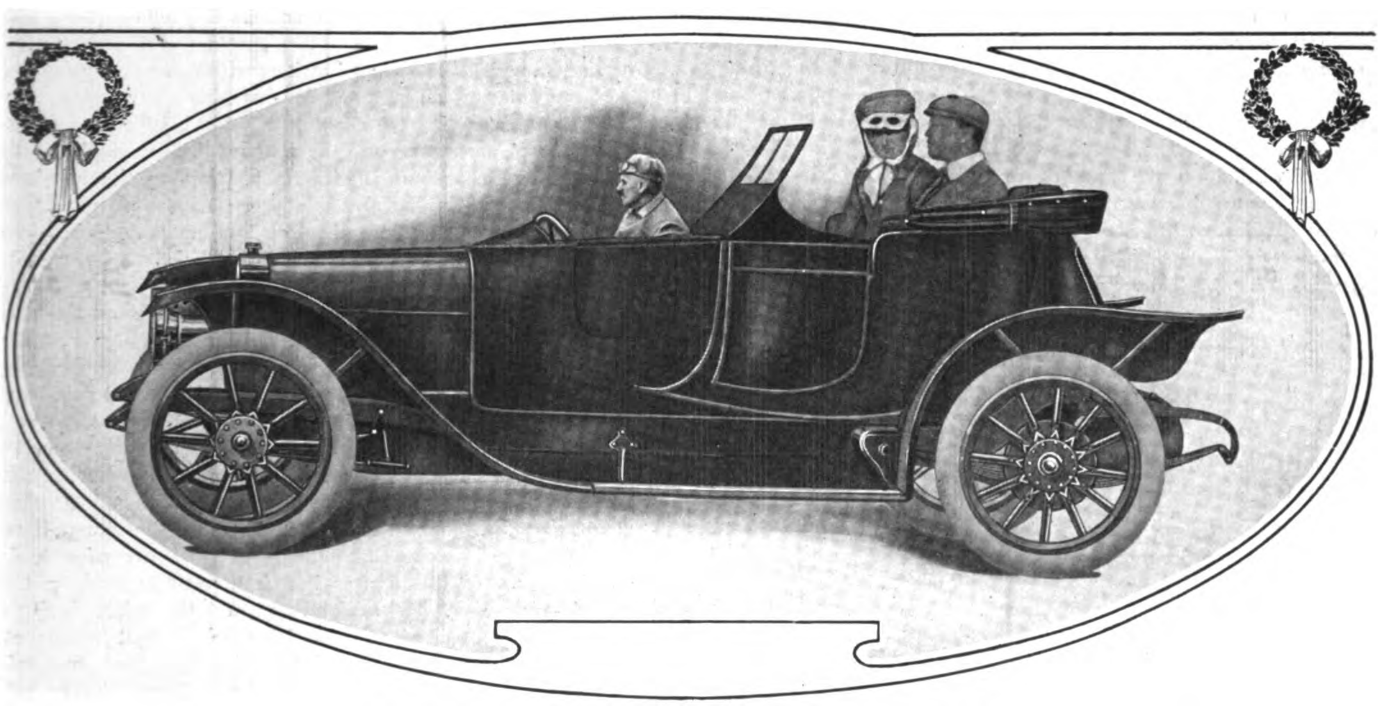

Fig. 1—Side elevation of a new type of automobile body providing a pit for the chauffeur and a separate steering equipment in the tonneau for the convenience of the owner

BODY MAKING, as it applies to automobile construction is an evolution of the carriage-makers' art. Carriages in the old days were not used for touring, due to the fact that horses were incapable of covering distance on a touring basis. The covering of considerable distances by automobilists introduced a new set of requirements, but there is a certain lack of harmony between these new requirements and the manner in which they are being coped with by the men whose experience was founded upon the carriage-makers' idea of the fitness of things. In a recount of the growth of the automobile industry the automobile came into vogue the footman was dispensed with and the coachman was supplanted by a chauffeur, so called, to accord with the newer need. The chauffeur, in addition to directing the movements of the automobile, was supposed to have a certain measure of mechanical skill, and when automobiles first came out it is more than likely that the requirement of mechanical skill greatly exceeded the demand, measuring the capability of the mere driver. When the chauffeur pre-empted the best seat in the body of the automobile, and held it against all comers, the signs of revolt on the part of the other occupants of

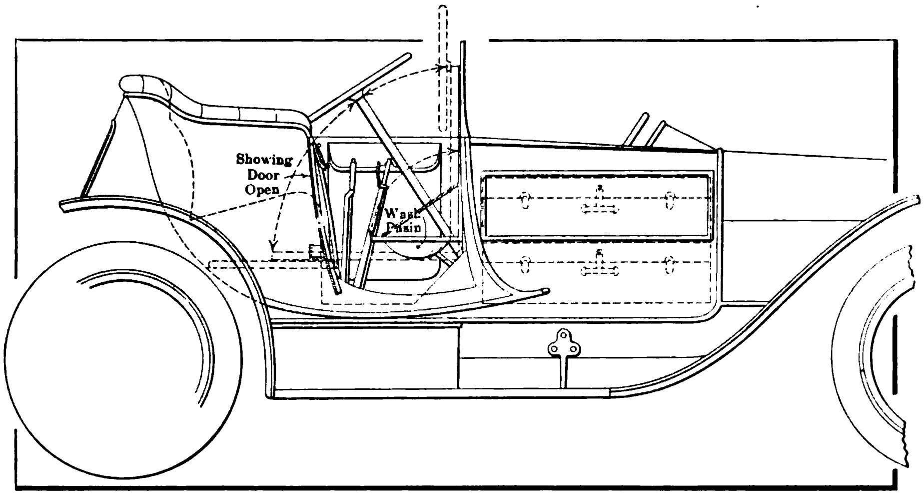

Fig. 2—Right-hand side of the new body, showing the storage of suit cases alongside of the chauffeur, the arrangement of the owner's steering gear in the tonneau, and a folding wash-basin taking water from a tank suitably disposed in the compartment in front

the car were too feeble to attract attention, but a change is coming over the field of automobiling, due to the fact that the mechanical skill idea is no longer a pressing necessity, and as matters stand to-day the best type of chauffeur is represented by the fellow who will have the good sense to keep the automobile clean, replenish the supply of gasoline and lubricating oil, keep the tires inflated, and drive the machine conservatively.

But the chauffeur still sits in the best seat in the automobile, and this fact, instead of being traced to the necessities as they obtained in the past, is the price of lack of ingenuity on the part of designers of bodies, in the face of persistent complaint that is well founded. When the owner of a car invests the best part of $5,000 in an equipage he will have great difficulty in getting a satisfactory return upon this investment if the work that the automobile does is confined to the mere effort of taking him to his office in the morning and back again at night, together with an occasional jaunt in which the owner's family may be permitted to join in the sociability, but there is a distinct expression of dislike on the part of many owners of automobiles, founded upon the experiences of the past, resulting in grease-smeared ladies' costumes and affronted sensibilities, without reasonable ground for objection, since, in all fairness, the chauffeur must be given a place of his own if he is not to occupy a position in the part of the car that is to be devoted to the service of the owner. As a parallel case, the owner of a steam yacht is freed from the objections of contact with the men who work around the machinery thereof, and, for that matter, the engineers who do the work enjoy the advantages of privacy, but this happy situation is at the expense of providing a place for the workmen as well as a place for the owner.

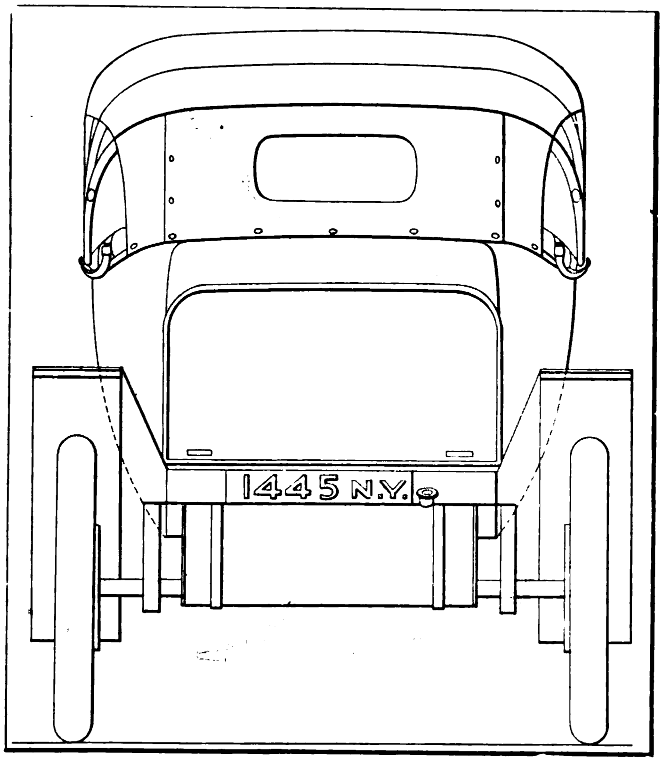

Fig. 3—Rear elevation of the body on a Guy Vaughan chassis, showing the trap door through which access may be had to the tires and tools as they may be stored within

In town car work, since the mechanician has a seat of his own in a position of vantage, those who enjoy the pleasures of this type of car are in a position to voice strong sentiments in favor of the embodiment of the same idea in types of automobiles that may be devoted to long-distance traveling, and it is from this class of the owners of automobiles that the best information comes, they being strongly in favor of providing a seat for the chauffeur and a compartment for the storage of such wearing apparel as must be taken along if a tour is to be under the most pleasurable conditions. When the automobile ranked as a novelty pure and simple there were not so many objections to tourists who might come into the dining-room of a first-class hotel looking like tramps and, to say the least, unkempt; but public opinion is decrying these conditions, and the time will no doubt arrive when tourists will be expected to repair to a room and make a change of costume before appearing in a dining room and in the public parlors of well-kept hostelries.

For the purpose of showing that it is within the realm of possibility to so design an automobile that there will be a place for everything, including the chauffeur, Fig. 1 is offered, presenting the general appearance of the automobile, in which it will be seen that the chauffeur is given a position on the left-hand side of the body, bringing the side levers on the fore and aft center lines, and the steering wheel so low down that the occupants of the owner's seating space would scarcely be able to observe that there is a chauffeur in the car.

The space alongside of the chauffeur is taken up for the storage of suit cases, and a study of Fig. 2 will suffice to indicate the scope of this arrangement, showing two suit cases in the compartment with some space above them for the storage of rugs, coats, etc. Fig. 2 also shows the entrance to the tonneau as it is provided at the right-hand side, bringing into view a new idea which may be briefly described as follows: Remembering that nearly every owner of an automobile has a penchant for driving, and taking into account the fact that the owner would not care to go down into the chauffeur's "pit" in a car of this design, it is a part of the plan as here contrived to equip a tonneau with a master wheel, side levers and the other facilities essential to the control of an automobile, with a means whereby the owner can unship the chauffeur's steering gear and take charge of the driving of the automobile without further ado.

A Place Is Made for the Storage of Tires and Cases, Also for Tools

When the owner gets tired of driving he may reship the chauffeur's gear and instruct him to undertake the responsibility of driving. In order, however, that the steering column as provided for the owner in the tonneau might not prove discommoding in certain respects, it is provided with means and mechanisms for folding back out of the way, thus leaving it entirely optional with the owner of the automobile to drive or not as he wills, or to remove the evidences of his driving facility and take advantage of the extra space afforded thereby.

The back of the car is shown in Fig. 3 with the gasoline tank attached to the chassis frame, and the license number with means for illumination at the back taken care of as a part of the design of the automobile. Referring to Fig. 4, which is a plan and elevation of the new design, it will be seen how two spare cases are stored in a compartment within the body lines above and slightly to the front of the rear axle with access to these cases through a trap door at the back of the body. In addition to the storage of cases in the back compartment there is room for tools and the design contemplates a definite position for each tool required, and a method of fastening the same into its place so that it cannot go adrift or make noise. Moreover, the arrangement is such that the owner of the car can see at a glance if there is a single tool missing from the kit. With the tires and tools provided for in the back compartment and a Yale lock on the trap door, nothing is left to chance in this quarter, and a considerable measure of the touring responsibility, especially of the harassing sort, is done away with. The space at the front on the right-hand side for the accommodation of two suit cases provides for a regulation size of cases 9 inches deep, 18 inches wide by 33 inches long; this space is dust-proof, and suitably lined with means for fastening the cases down so that they will not rattle and become chafed. In addition to the provision for suit cases and the storage of rugs and coats a water-tank is provided and a folding water-basin is also fitted into place with means for opening the same back into the tonneau. This basin is shown in the open position in Fig. 2, it being contrived in substantially the same way as the folding basin of this character in Pullman compartment cars. In the illustration Fig. 4 provision is made for a searchlight, the latter being back of the dash line, convenient to the chauffeur, with means for hand-control. It is the idea in connection with this body to use electric lights with a dynamo for generating the electric current, suitably attached to the automobile motor. It would be optional to use the searchlight; it may be removed at will, and Fig. 1 shows the body in elevation with the searchlight removed.

Motor Laws in New Brunswick—The New Brunswick Legislature has enacted some laws which are of interest to automobilists who reside in or drive through that province. Here are some of the stipulations: A chauffeur's license may be canceled after two convictions. A higher standard of brilliancy of lamps is necessary. Car numbers must be 4 inches high, instead of 3 inches, as formerly. The motor car speed has been reduced to 20 miles per hour. Some members of the Legislature from the country districts introduced resolutions of a decidedly freakish nature, one of which demanded that cars should not be used on one day in each week. The amendment was shouted down. A tax, which will be given over for the improvement of the roads of the province, was approved, this tax ranging from $5 to $25 on automobiles of from 25 to 50 horsepower.

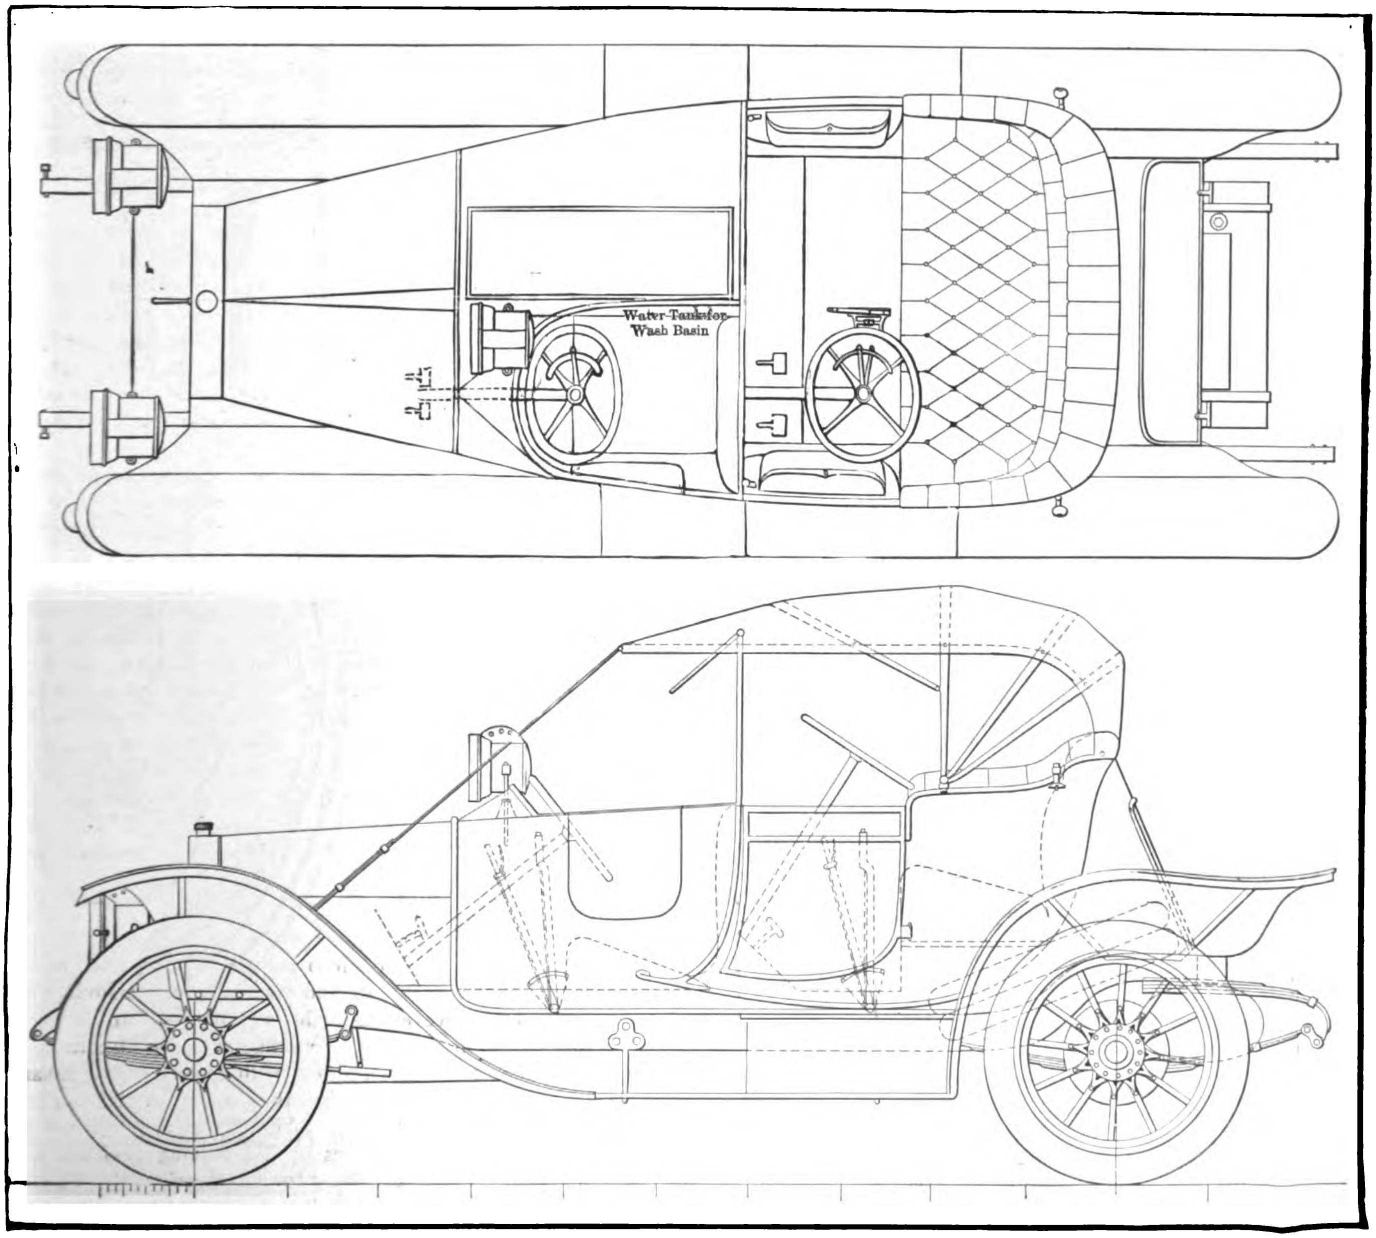

Fig. 4—Plan and elevation of the new body, showing the double steering equipment in dotted lines, also the storage of tire cases. The sealed compartment for suit cases is at the right of the driver's pit

AB—Scaife valve motor with piston valve
AC—Watkins motor operated by sleeve and piston

The files of the Patent Office are storing at the present moment several worthy ideas upon the sleeve valve situation which will no doubt some day fructify. Some of the types here presented have passed the stage of trial and have become commercialized propositions. In the following treatise the piston valve has been dealt with in various forms as it has appeared, besides showing several designs of external sleeve motors.

THE various methods of operating sleeves for gasoline motors described in the last number of THE AUTOMOBILE dealt more particularly with such types where either the sleeve or sleeves were caused to reciprocate or rotate. Many of these motors have long since passed the experimental stage, but as in the case of all inventions pioneer work is very slow.

Parker Uses a Somewhat Complicated Method

wall and the water cooling space C. At the base of the piston P the working piston and the sleeve are joined together so that with the reciprocating motion of the piston A the sleeve is forced to reciprocate as well. The semi-rotary action of the sleeve is obtained by fitting the sleeve with a pivot P1, which engages in a slot in the exterior wall W. The slot is indicated by dotted lines with a lower apex at E. The longitudinal section L shows how the wall W is slotted in order to accommodate the pivots P1 and P2. It is a question whether the power required to guide the pivot in the slot will not take away from the general efficiency of the motor.

Reader Motor Employs Rotary Valve in Head of Motor

Another form of rotary sleeve valve motor is shown in Fig. Y, being the composite production of F. J. Reader, A. E. Taggard and E. A. Wilderspin. The mechanism consists of a rotary valve A which surrounds the cylinder C, the valve having a port or ports adapted to register in rotation with the inlet and exhaust ports of the motor. The valve A at the outer end of the cylinder C surrounds the cylinder; the rotary motion is imparted by bevel gear set B1 and B2 and thence by a vertical shaft to the pinion P1. This pinion is clean on the upper end of the shaft S and meshes with the teeth T1 formed on the lower end of the valve A. The cylinder C1 has a downward protruding flange C2 which surrounds the valve A, so that the main part of the valve lies within an annular space between the flange and the cover of the cylinder. Adjustable lock nuts are provided on a screwed portion of the cylinder for adjustment of the valve ring, and ball races H and H1 are interposed between the lock nuts and the lower edge of the flange. Ports P2 and P3 are provided in the valve ring A which uncover the cylinder ports O1.

Bingham Piston Valve Motor Has Good Points

The adaptations of the sleeve are legion and at a later date further applications of this type will be given. A type of motor that has been placed on the market commercially and which deserves more than passing mention is what is known as the piston valve motor. This school has several adherents and the methods of operating the piston are numerous. Some favor an overhead motion, others using the conventional eccentric shaft. One type that has been practically demonstrated in England is the Bingham piston valve. As shown in the illustration this is operated by an overhead eccentric shaft S1 and is rotated at one-quarter crankshaft speed, as the rectangular ports in the valves open to the cylinder ports on the down stroke as well as on the up stroke. A section of the motor is shown in Fig. Z. The piston P1 is caused to reciprocate in the cylinder C1, covering and uncovering the port P2 of the cylinder. During the power stroke the valves are not in lateral balance, and the surface of the valve subjected to the explosion pressure is equal to the area of the port. But as will be seen from the illustration the valve is very long; the thrust from the explosion is distributed over a considerable surface area. This motor has been modified in some respects and the valve operation has been effected by means of a connecting rod operating the piston from below.

Starr Motor Uses Sleeve and Piston

In the Starr motor the valve mechanism consists of a sleeve, shown in Fig. AA, inside a small cylinder A, and inside the sleeve there is a piston P1, both being operated from the eccentric shaft E1 by connecting rods C1 and C2. The piston P1 has 90 degrees advance of the sleeve S1. The eccentric shaft is driven at half speed of the crankshaft. The combustion chamber C3 is brought into communication with the intake and exhaust manifolds through the office of the sleeve S1 and the piston P1. The exhaust manifold is attached at M, and the intake I is provided with an annular cavity D and another cavity D1. As the sleeve S1 is drawn downwards the piston P1 moves upwards, and gives free entry to the intake. In a similar manner the upward motion of the sleeve S1 and the downward motion of the piston P1 the upper half of the piston uncovers the port slot and gives free egress to the exhaust.

The Skaife Motor Uses a Channel Piston As Well As a Sleeve

The Skaife motor is shown in section in Fig. AB and alongside the main cylinder C1 there is a cylinder C2. The sleeve S1 is operated by the connecting rod R1 set at 90 degrees to the connecting rod R2 which operates the piston P1. The eccentric shaft runs at half speed and the operation of intake and exhaust is similar to the preceding type with the exception that the intake is effected in the manner shown in the illustration. The piston P1 has a double-elbow passageway which connects the ports P2 and P3. As the sleeve mechanism is housed with the crankshaft no supplementary lubrication is necessary.

Watkins Motor Is Well Thought Out

Fig. AC is a cross-section of the Watkins motor (British Letters Patent No. 650). The valve cylinder E at the side of the working cylinder A contains a sleeve S1 which is adapted to reciprocate therein. The sleeve is operated by eccentric rods B and B1 which are mounted on the half-speed shaft S2 by means of sheaves. The half-speed shaft is driven in the usual manner by gear wheels. Fitted concentrically inside the sleeve valve S1 is the piston valve P1 adapted to reciprocate within it, being operated by the connecting rod B. M is the port opening into the working cylinder A. N is the port in the outer piston valve S1 communicating directly with the port M. O is the port of the piston valve P1 registering with the port N. I is the intake manifold connection. The port Q of the piston valve P1 and the port Q1 of the piston valve S1 are always open to the exhaust port R. The section of the motor shows the relative positions of the two piston valves and their ports on the working cylinder. The working piston H is at the bottom of the stroke, following the explosion stroke, and the ports N and O have just opened to allow the exhaust gases to pass through to the exhaust outlet R.

The Bostock and Drummond Motor Is Controlled by Horizontal Pistons

In the Bostock and Drummond motor, shown in Fig. AD, it will be seen that the piston valves are operated horizontally in the head of the cylinder C1. A is the inlet manifold connection to which the carbureter is attached and the illustration shows the eccentric shafts E1 and E2 operating the valves P1 and P2. The piston valve P1 is slotted and the same applies to the piston valve P2 so that the port P3 in the head of the cylinder becomes uncovered and allows the incoming gases to be sucked into the cylinder C1. It will be noticed that the piston P is of the spherical dome type. As the piston P rises on the exhaust stroke the piston P2 recedes inside the sleeve P1, allowing the port P3 to be uncovered and the exhaust gases to be expelled through the manifold M1. In order to facilitate the quick flow of incoming and outgoing mixture the cavity C2 is provided in the cylinder head. The sleeves are cooled by incoming gases through the manifold way, but this may have a detrimental effect upon the lubrication of these parts.

Sliding Block Sleeves Are Used on the Wridgway Motor

The construction of this motor is clearly shown in the illustration Fig. AE and is the invention of C. G. Wridgway. Two sliding blocks operated by rods R and R1, which are caused to reciprocate by a double eccentric shaft, open and close the ports P and P1, according to the four-cycle principle. As in most motors, there is a certain amount of pressure upon the sleeves during the explosion stroke. It has been the endeavor in this motor to overcome this by extending the piston head into two lobes L and L1, and the position that these occupy is shown in the illustration.

Foster Uses Separate Piston Valves for Intake and Exhaust

In the sectional elevation of the Foster motor, as shown in Fig. AF, this motor is of the single-acting piston valve type, the valve P1 in the axial line showing a portion of the working cylinder C1. The cylinder C2 of the valve is water-jacketed as shown; the port D1 leads from the combustion chamber to the piston valve. P is a stationary piston fitting within the upper part of the reciprocating valve P1. The interior space O inside the hollow stationary piston P is open to the water jacket W. The connecting rod R is operated through an eccentric shaft running at half engine speed. The valve P1 controls either the outlet of the exhaust gases or the inlet of the new charge. The port W of the piston valve is always open to the outlet port W1 in the valve cylinder wall. The ports R and R1 are placed around the valve instead of on one side only, and in the position shown in the illustration the valve is fully opened.

Brindley Adds Complication to Present Practice

In Fig. AG will be seen a motor designed by John Brindley, the principal points of difference between this and other piston valves being that springs are used and the reciprocating motion is obtained through the employment of cams. The piston valve A is operated by a push rod R, which in turn receives its motion from the fulcrum lever F. This is attached at one end to the pivot P1. Within the lever F there is a roller R2 which contacts with a cam C1, and as this is rotated by means of intermediary gearing the piston valve is caused to reciprocate. The spring S holds the roller R2 in contact with the cam C1 so that on the downward stroke the roller follows the cam formation. As the roller passes over the hollow of the cam the valve A uncovers the port P and allows the gases to be sucked through the intake manifold I into the cylinder C. The upward motion of the piston valve again uncovers the port P after the explosion stroke and allows the exhaust gases to be emitted through the exhaust manifold E. The motor works on the ordinary four-cycle principle. One point about the disposition of the exhaust manifold and the relation of the piston A1 is that the gases pass through the port P, while the valve A is entirely out of the line of trouble.

Mascord Utilizes a T-Shaped Cylinder with Two Valves

The accompanying illustration Fig. AH shows a sectional cut of the Mascord motor, in which the valves are provided on either side of the cylinder C1. The valves V1 and V2 are operated by cams C2 and C3. The inlet valve V1 is a cylinder closed at the lower end, and having its upper extremity fitted with piston rings, P1. The lower part is closed and is connected to a rod R. A gland G1 surrounds the lower part of the cylindrical valve, by which the pressure for one or a number of split packing rings may be adjusted, so as always to maintain a gas-tight joint between the lower part of the casing and the lower part of the cylindrical valves. A spiral spring S1 is mounted between the gland and the boss on the rod R1, maintaining uniform pressure. The intake manifold is attached at I, and the exhaust at E. The slots S and S1 in the cylindrical valves allow the gases to pass through them into the respective manifolds.

Royce Favors Overhead Piston Valve

The section of the motor shown in Fig. AI is of the design of Royce, manufacturer of the Rolls-Royce car in England. Two overhead pistons are employed, P and P1, working in cylinders A and B, located on the right and left-hand side of the combustion chamber. The pistons are provided with piston rings and are operated from eccentric shafts E and E1 through connecting rods C and C1, vertical push rods R and R1 and a link motion L. The piston valves work at half speed of the crankshaft. The shaft S1 lies in the center line of the auxiliary cylinder A so that at the time of the explosion vertical pressure is transmitted to the lever system. The operation of the engine is as follows: After the piston P2 has reached the top dead center, the piston sleeve A opens the inlet port I, keeping it wide open during the suction stroke, and closing it at the beginning of the compression stroke. The levers S1 and K then take dead-center position in the auxiliary cylinder at the moment the explosion takes place. After the working piston P2 is about to reach the lower dead cente[illegible] sleeve P1 opens the port E2 and the exhaust gases are exp[illegible] To add greater rigidity to the lever system the connectin[illegible] rods C and C1 and rods R and R1 are connected to a cylindrical guide. The lever M is placed externally to the axis N1.

Another Adaptation of the Bingham Motor

In Fig. Z the method of operating the Bingham motor was shown, with an overhead eccentric mechanism, but in Fig. AJ, which is a section of another type of Bingham motor, the sliding piston valves are operated from eccentrics placed in the crank chamber. The auxiliary cylinders A and B are located laterally in respect to the main cylinder. The pistons P and P1 are operated by connecting rods C and C1 from the eccentric shafts E and E1. The pistons are fitted with piston rings. The pistons' valves have slots F and F1 cut in them which communicate with the two ports in the head of the cylinder C2. The explosive pressure in this case is not taken by the actuating levers, but by the surfaces of the piston valve. Lubrication of this type of motor is very simple, as the auxiliary cylinders are in direct communication with the crank chamber.

Hewitt Piston Valve Motor Has Been Used Commercially

The Hewitt motor shown in section in Fig. AK differs from other motors of the piston-valve type, as will be seen from the accompanying illustration, inasmuch as the auxiliary cylinder is placed at an angle instead of parallel to the main cylinder. The four-cylinder motor of this type is cast in pairs, and presents somewhat of a square shape. The inlet and exhaust piston valves are situated together on the left-hand side of the motor. The illustration shows the main piston P in the working cylinder C and alongside it the auxiliary cylinder C1 with its piston V. These valves are operated by connecting rods from a secondary crankshaft driven by gearing from the main crankshaft at half speed of the latter. There are eight valves in all, four exhaust and four intake. Referring to the illustration, the form of the combustion chamber will be noticed, and upon the firing stroke the pressure of the explosion moves the exhaust valves three-fourths of their outward stroke until the piston V uncovers the port P1, thereby delivering power through the half-time gear wheel to the main crankshaft C2, which will correspond to an increased expansion of the charge of approximately 20 per cent., but deducting the low efficiency of the half-speed lay crankshaft, the net increase of power should be in the neighborhood of 10 per cent. The cycle operations of the valves of this motor are shown in Fig. AL, the valves being placed on either side of the working cylinder for simplicity only. Fig. (B) in Fig. AK shows a cross-section through one of the intake valves.

Single Piston Is Used on the Smith Motor

Fig. AM (A) shows the manner of operating the piston valve of the Smith motor by means of a camshaft C1 and a lever L1 which is fitted in one extremity to a pin P1, and a roller R1 contacts with the cam. The roller is held in contact with the cam by means of a spring S1. The piston valve P is moderately moved from the path of the exhaust gases during the exhaust stroke and works in a water-jacketed cylindrical valve chest, controlling a single admission and exhaust port B. During the suction stroke the combustible mixture is admitted to the working cylinder by the upward movement of the piston valve P which uncovers the port B to the inlet port P1. Upon the completion of this stroke the piston valve has attained the position shown in the illustration. At the beginning of the exhaust stroke piston valve P descends and uncovers the port B, thus permitting the exhaust gases to be driven out to the port P2. The lower inner face of the port B at the end adjoining the piston valve chamber is made higher than it is at the other end next to the working cylinder, in order that the exhaust gases passing through the port may be deflected upwardly away from the end [illegible]e. In order to accommodate the rings with a good [illegible] iston valve P the metallic bridge F is formed of the a[illegible]nnder. This prevents the ring of the piston valve from [illegible]ering the port. The bridge is hollow, and its interior is in direct communication with the water cooling system in order to maintain it at a uniform temperature. This is shown in (B) of Fig. AN.

A Simple Adaptation of the Single Piston Valve

The sectional cut of this motor, which is the invention of Henry Berry and G. H. Mann, shown in Fig. AN, works on the conventional four-cycle stroke. The working cylinder C1, wherein the piston P1 which has a concave dish reciprocates, has a port P2. The valve box B1, containing the inlet opening I and the exhaust opening E, is fitted with a single piston valve V carried on a rod R1 capable of sliding in guides G and G1. The lower end of the rod R1 is connected by means of a pivoted link L to the shorter arm of the bell crank lever strap S situated on the eccentric E1. The eccentric shaft is coupled up to the engine shaft by a rod R2. By this means the valve V1 is caused to reciprocate in the valve box B1 and alternately place the intake and exhaust ports in communication with the cylinder.

Pieper Piston-Valve Motor Uses Novel Method of Operating the Valves

The valve consists of a piston which slides up and down so as to put the cylinder port B in communication with either the inlet passage C, as shown in Fig. AO, or with the exhaust outlet D. It has been the object of the inventor of this motor to do away with cam operation, and in order to obtain a rapid movement of the piston A and periods of dwell while the ports are open, the piston valve rod E is connected to a rocker F, one end of which is connected by a link G to a crankpin on a shaft running at engine speed. The other end of the rocker F is connected by a link H to a crankpin on a shaft running at half engine speed, thereby providing a quick opening and closing with a period of dwell when the ports are open.

CAPE BRETON, Canada, people now own 15 automobiles which were made by an American concern with a factory in Walkerville, Ontario. There is an import duty of 35 per cent. on foreign-made automobiles, to which the agent's commission of 20 per cent. is added. The touring cars of the type just mentioned are sold in Walkerville for $875, the outfit including windshield, top and lamps.

What Fuel Costs in Truck Operation

Gasoline and Current in Ton-Miles

Based upon an immense and typical experience in automobile truck operation it is found that the ton-mile cost of gasoline is .0087, lubrication .00304, a total of .01174, while the item of expense for current used in propelling electric trucks is .0317 per ton mile, which, with lubrication at .00086, makes a total cost in this particular of .03256. The two-ton electric and three-ton gasoline cars again demonstrated their economy as against that of the smaller sizes of both types of freight automobiles.

WHEN the business man decides to investigate the proposition of replacing his horse-drawn delivery and transfer service with automobile trucks one of the first detailed items that presents itself to him for solution is the cost of gasoline for the operation of gasoline trucks and electric current to drive vehicles of that character.

If he has been systematic in conducting his horse-drawn equipment and if proper detailed records of costs have been kept he knows exactly what it costs per wagon-mile to transfer his freight for each of a dozen different factors that go to make up the sum total of cost. If he has carried his records a little further he knows the ton-mile cost for operation and also the ton-mile cost for each item of operation.

There are many business men who have kept such records with care, but, of course, the vast majority have not done so, and all that their records will show is the cost of operation on gross figures. A detailed record of this kind would prove exceedingly valuable to the business man who to-day is confronted with the stringent necessity of changing his system of transfer and delivery. It would form a solid basis for comparison with both electric and gasoline trucks that would help him immensely in getting maximum service from his equipment at minimum cost.

But to go back to the subject: The cost of gasoline and current is one of the salient items of truck operation, just as tires, repairs and supplies also bear an intimate relation to the total.

The following article takes up the cost of gasoline and electric current actually used in the operation of 634 trucks, 412 of them being electrics and 222 being gasoline cars. The figures submitted cover four years of operation under actual service conditions. If anything beside the exact truth, the total figures per ton-mile as given here are a shade too high, because many of the trucks used in the illustration have been in service for several years and as a consequence are not quite as economical of fuel and current as the most modern types of freight automobiles may be.

However, nothing that approaches the facts and conclusions of this article in the way of exact data has ever been published on this subject. The average mileage of all gasoline cars considered was 28.3 miles per day, including every day in the year whether in service or not. As a matter of fact they were in actual use a trifle over twenty days in each month, the difference between the actual length of the month and the service being accounted for by holidays and lay-ups for repairs, adjustments and other things as well as the general exigencies of business.

The actual mileage of the gasoline cars on working days or days in which they were used was 42.5 miles. This would give a total of 850 miles a month and 10,200 miles a year. It may be well to note that all the cars could have done more service if they had been pressed to do so.

The sizes of gasoline cars considered as far as freight-carrying ability is concerned were those of 1 1-2-ton and 3-ton sizes. Thus, on a basis of 365 days' work in a year, delivering 28.3 wagon miles, the gasoline trucks delivered an average of 63.67 ton-miles for each day in the year.

Actually, figuring on a basis of twenty days' service in each month, they made 42.5 wagon-miles a day on the average, and consequently 85.62 ton-miles at full capacity.

Now getting down to the cost of gasoline used in furnishing power for these cars, it is shown in the reports of their operation that it cost an average of .0221 per wagon-mile for the fuel used on the three-ton trucks. This would give a ton-mile cost for gasoline of .0074, which was far and away the best showing made in this particular. The wagon-mile cost for gasoline for the three-ton trucks varied between .0199 and .0243, with the average precisely between these two extremes.

Of course all the wagon-mile and ton-mile figures are based upon actual mileages for periods of real service.

With the trucks of one and a half tons' capacity the showing is of a materially higher cost for fuel per ton-mile, although the wagon-mile expense is considerably lower. It was found that it cost from .0147 to .0159 to operate these trucks each mile. The average was .0153. This would give a basis for a ton-mile cost of .01. The average ton-mile cost for gasoline, considering all the trucks used in this illustration, was .0087.

To give some idea of the tremendous number of wagon and ton-miles used in gaining these figures it may be said that 28.3

was the average daily mileage of all the trucks. This would give an exact total mileage per year per truck of 10,329.5 and a four-year total of 41,318, or a grand total of 9,172,596 miles, which is equal to 367 circuits of the earth on its equator. As to the freight-carrying feature, that number of wagon-miles means 20,638,341 ton-miles. At an average cost of .0087 per ton-mile for the gasoline used, the daily cost per wagon would be .553929, and per month $16.64 and per year $199.68, and for the four years $798.72, and for the whole 222 trucks $177,315.84.

It should be distinctly understood that lubricating oil is not included in these figures.

Summed up they show that the three-ton truck is 24 per cent. more economical in the transportation of one ton of freight for one mile than the truck of half its size, and that the general average ton-mile cost is .0087.

In taking up the subject of the cost of current for the operation of electrical trucks it should be constantly remembered that the figures herewith do not take lubrication into consideration in any way. Naturally the electrics are entitled to some consideration and a material credit in this matter, because while there is no similar item regarded in the figures on gasoline truck operation, if it were regarded it would be very much larger for the gasoline cars than for the electrics. The difference is probably as much as .00218 per ton-mile in favor of the electric cars.

The average mileage of the electric cars is 20 per day for every day in the year, and the service is about 20 days a month, the same proportion as was shown for the gasoline-propelled vehicles. Of the 412 trucks tabulated, 209 were of two-ton capacity and 203 of one-ton size. Due allowance must be made for this apparent discrepancy in service because Sundays and holidays are included, and it should be remembered that many of this big array of electrics have been in daily use for many years, the difference being emphatically marked as against modern gasoline cars.

The current cost per wagon-mile for two-ton trucks ranged between .0474 and .0442, considering both acid-lead and nickel-iron equipment. The average cost per wagon-mile was .0458 and the ton-mile cost of current for this type of wagon proved to be .0229.

As compared with the cost of current for one-ton wagons, this showing is remarkable because it has been found that the one-ton truck is far less economical in this respect. The cost was .0406 on the general average for this size of truck, which is not far from the wagon-mile cost of the wagons twice the size. As the smaller trucks were of one-ton capacity, the wagon-mile cost of gasoline is the same as the ton-mile cost.

Thus the average cost for both sizes of electric trucks was .0317 per ton-mile. The average electric truck delivered 30 ton-miles per day, thus the cost of current per day was .9510, which would make $347.115 per year and $1,388.46 for the four years of service, or $572,045.52 for the whole fleet during the four years.

The average monthly mileage for the electric cars being 600, the yearly mileage would be 7200; the distance traveled in the four years per car would be 28,800, and for the 412 trucks 11,865,600. This represents 17,798,400 ton-miles.

Taking a general view of the cost of operating mechanically-propelled freight vehicles the figures here adduced show the following facts: The data considered shows that gasoline trucks delivered 9,172,596 wagon-miles and 20,638,341 ton-miles in four years at a cost of $177,315.84, or .0087 per ton-mile for fuel.

The electrics cost over three times as much for current per ton-mile as the gasoline cars required for fuel. The total number of wagon-miles made by all the trucks was 21,038,196, and the ton-miles involved were 38,436,741. The average cost for gasoline and electric current proved to be .0202 per ton-mile, taking all the cars into consideration.

Experience has shown that lubrication is more uncertain in its costs than gasoline and current, but a fairly exhaustive examination of the field tends to show that the average cost of oil and grease for the gasoline car approximates $70.75 in an average year's running service. This would mean a per ton-mile cost of .00304 for lubrication.

With respect to the electrics it has been found that the average yearly expense for lubrication was only $9.41, which would indicate a per ton-mile cost of .00086. The difference in favor of the electric car on that basis would be .00218 per ton-mile. This may not be precisely the difference, but it is surely within a small fraction of a mill of the actual figures.

On this kind of a foundation the per ton-mile cost of current and lubrication for all the electrics considered in this article would be .03256, and the ton-mile cost of gasoline and lubrication in the gasoline trucks would be .01174.

As has been noted in previous articles on truck operation, the two-ton electric and the three-ton gasoline types were far more economical in operation than those of smaller size when the figures are reduced to a basis of ton-miles. It is only reasonable to assume that this tendency may be carried out with sizes that are materially larger than those used as the foundation of this article. However, actual figures touching upon this feature of truck operation are not yet available, so the theory cannot be said to be proved in practice.

New Fire-Fighting Apparatus

New York City in a Receptive Mood

The time is now ripe for the general adoption in New York City of automobile fire engines, and it behooves those who can furnish the apparatus to carefully consider what is required of a system that can replace that which is now in use and has been found capable of fulfilling its office in the vicissitudes of actual service. The day of the specialist is here and this must be remembered in constructing both the truck and the pump.

ROME was not built in a day nor was it built through the brilliant achievements of a lone emperor, general or statesman. The united efforts of those who were foremost in their own particular art accomplished the works of law, art and military science which have been handed down to us. For a wagon maker to try to build a pump which will be good enough to replace the results of years of experimenting and study on the part of those most expert in the science of pump building is as futile as the efforts of our leading pump builders to produce a truck which will supersede the efforts of the specialists in the science of truck building.

A successful fire engine must be as much of a success when it arrives at the point of duty as it was when it was on its way to that spot; and also it must be considered that the best pump on earth is no good to any fire department if it arrives on the scene long past the time when it should have been forcing a flood of water on the fire. The present-day apparatus is not a failure and it is not on such a basis that there is a wild desire to get rid of it and replace it with anything which may present itself; but there is a sane desire to improve it. The automobile has superseded the horse in other lines of work and will no doubt do the same thing in the way of transporting fire ap-

A—Robinson auto fire engine throwing water from three 2 1-2-inch lines

D—Motor-driven pump on the Knox fire engine

paratus, that is, if the quality of the apparatus is of such a nature as to warrant its use in place of that now employed.

The time is now ripe for such a change. The field is open for the manufacturer who can bring forward a fire engine that will not be the product of either a truck builder or an engine builder, but the combined efforts of the two. To be able to produce such a machine a thorough knowledge of the problem on hand will be necessary, and this knowledge will necessarily consist of an understanding of the policy to pursue to secure a fair trial with a good prospect of the adoption of the machine should it perform in a manner that would justify such adoption and an accurate conception of the requirements in terms of the facilities now on hand. The former will have to be left to the judgment of the manufacturer, while the latter may be partly supplied by a resumé of the situation as it now stands.

The Hydraulics of Fire-Fighting

The fire-engine question resolves itself from the start into two divisions which are entirely independent of each other. The first part of the matter deals with the transportation of the apparatus, while the second has to do with its operation after it has arrived on the scene of its activities. The high-pressure system obviates the necessity of transporting pumping apparatus by centralizing the plants and feeding water directly to the high-pressure hydrants in the various parts of the city.

The capacity of the fire-fighting pump, as well as any other piece of pumping machinery, can best be considered from a gallon-per-minute standpoint, that is, the ability of the pump to deliver a given quantity of water in a given time. The determining points of the quantity of water delivered will be found to be the pressure at the nozzle and the diameter of the nozzle.

In order to deliver the water at a certain pressure at the nozzle, the pressure at the pumping station, whether it is a fire engine, fire boat or high-pressure pumping station, will be entirely governed by the size and length of the hose line and the bore of the nozzle. To illustrate this fact a practical case may be taken: with a required nozzle pressure of 80 pounds, a two-and-one-half-inch hose line and a length of 400 feet, the pressure at the engine or high-pressure hydrant must be 150 pounds, using the best grade of rubber-lined hose and a smooth nozzle one inch in diameter. If, however, the bore of the nozzle were changed to one and one-half inches instead of one inch, all the other conditions being kept the same, for an engine pressure of 150 pounds, there would only be a pressure of 36 pounds at the nozzle. A variation in the length of the line would, of course, affect the nozzle pressure in a similar manner.

Besides affecting the engine pressure, the quantity of water thrown in a given time is naturally directly dependent, for a definite nozzle pressure, upon the size of the nozzle. Any calculations for the quantity of water discharged per unit of time may be worked out by formulæ involving the diameter of the nozzle and the pressure at that point. Such a formula will be given later, after a brief consideration of the fire apparatus now in use in Greater New York.

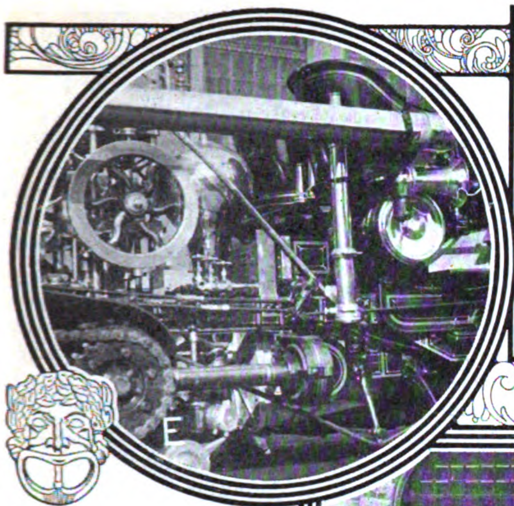
The theoretical range of the stream may be calculated from the gallons per minute of discharge and the size of the nozzle. This, however, is affected to such a degree by wind and other practical considerations, that it is of no real value except, perhaps, as a means of judging the results to be expected.

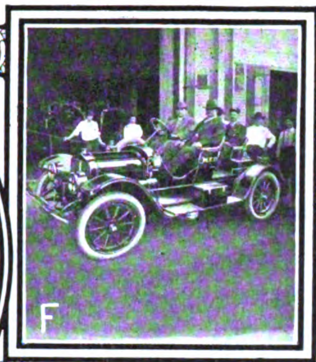
In the boroughs of Manhattan and the Bronx in New York City the largest fire engine pumps in use have a stroke of 9 inches and a bore of 5 3-4 inches. This pump is of a size known as "extra first" and has a reasonable capacity of about 1,000 gallons per minute. To obtain this capacity through different sets of hose lines and nozzles, with a piston speed of about 400 feet per minute, which is about the usual practice under a steady load, the engine pressure will vary with the number and length of lines used and the size of the nozzles.

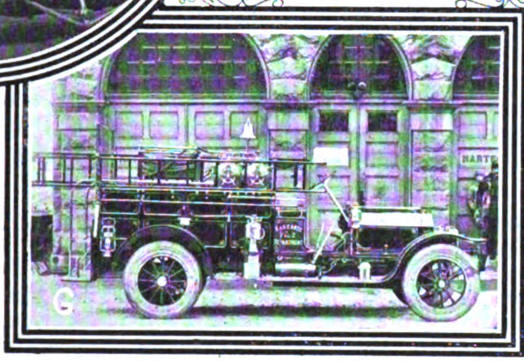
Fire Equipment of Greater New York

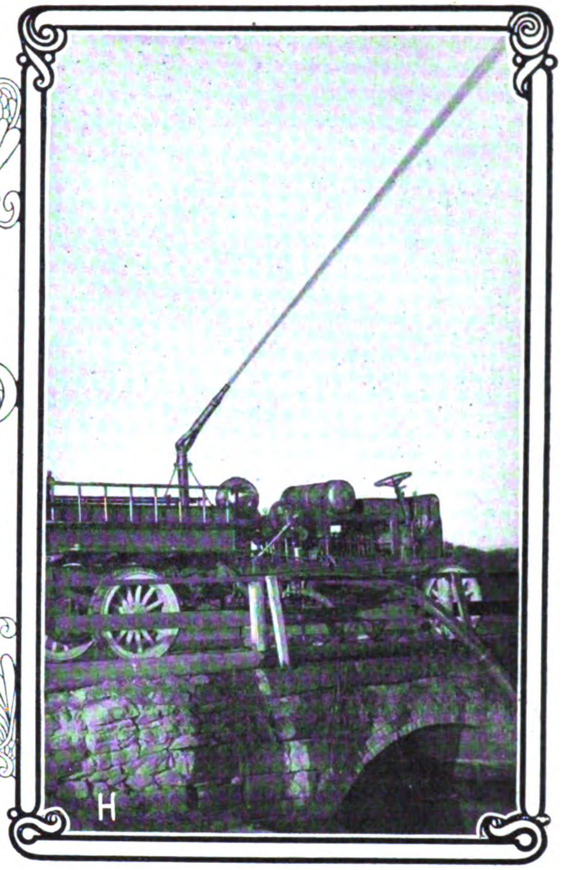
In the boroughs of Manhattan and the Bronx there are two of the "extra first" size pumps in use, one with the dimensions given above; the other, while of the same bore, 5 3-4 inches, has a stroke of 8 inches. The reasonable capacity of both these pumps is 1,000 gallons per minute.

Of the remaining 85 steam fire engines in the two boroughs,









E—View of a motor-driven water pump in chassis

F—White gasoline car used as chief's wagon

H—Modern type of automobile fire engine sucking water from a stream

G—Kissel Kar chemical truck

there are 28 of the "first" size, having in the majority of cases a stroke of 8 inches and a bore of 5 3-4 inches. The rest are "second," "third" and "fourth" sizes and range from the size mentioned above, for the "first" size, down to as low as four-inch bore, in the "fourth" size.

In addition to the regular fire engine equipment noted, there are 26 steam engines and seven of the fire fleet. The spare steam engines are distributed about the two boroughs and are kept for emergency purposes.

The boroughs of Brooklyn and Queens are equipped with 81 steam engines and two of the fire fleet. Of the 81 steam engines, 6 are of the "first" size, 15 of the "second" and the remainder of the "third" and "fourth." The stroke and bore of these engines are the same as the stroke and bore of the Manhattan and Bronx engines of corresponding size.

The borough of Richmond has 8 steam fire engines, all of which are of size 4, having a stroke of 6 inches and bore of 5 1-2 inches, with one exception, this pump having a stroke of 7 inches and a bore of 4 inches. The fireboat "Zophan Mills" is included in the Richmond Borough apparatus.

The boroughs of Brooklyn and Queens have 9 spare engines and the borough of Richmond has 3.

Coping with Water-Front Conflagrations

The fire fleet of the marine division consists of ten fireboats which are equipped with pumps. The "New Yorker" is the largest, her pumps having a total capacity of 12,000 gallons per minute. Next in size are the "James Duane" and "Thomas Willett" each with a capacity of 9,000 gallons. The "Cornelius W. Lawrence," "Abram S. Hewitt" and "George B. McLellan" have a capacity of 7,000 gallons while the "Zophan Mills" and "William S. Strong" have capacities of 6,000 gallons per minute. The two smallest are the "David A. Boody" with 5,000 gallons capacity and the "Seth Low" with 3,500. The total capacity of the fireboat fleet is 68,500 gallons per minute.

To give an idea as to how the water is distributed and the methods in use on the fire boats, it may be well to give a short description of representative boats. The pumps aboard the newer boats are of the centrifugal type, while the older boats use the reciprocating form of pump. We will take the "New Yorker," however, as a fair example of the distribution of the water supply on the majority of fireboats now in use, and the "Thomas Willett" and "James Duane" as examples of fireboats using the centrifugal type of pumps. The rating of the two latter boats while not so high as that of the "New Yorker" is probably below the maximum available capacity of the pumps.

The Fireboat "New Yorker" has four duplex pumps each with a free outlet capacity of 3,250 gallons per minute. This capacity is reduced of course, when the outlets are connected to the lines; and becomes about 3,000 gallons per minute for each pump. The capacity of the pumps depends directly on the back pressure caused by a small nozzle or a long line. These pumps are of the reciprocating type and are double acting, the water cylinders being 11-inch stream by 10-inch bore.

There are two currents mounted on the vessel, each being surmounted by a Glazer standpipe. The outlet of the Glazer standpipes can be regulated from 1 1-2 inches up. There are eight 3 1-2 inch outlets on each turrent and one 6 inch.

The lines of hose carried on the three reels, which are placed on the deck, consist of two reels, each carrying twenty lengths of 3 1-2 inch hose, and one reel with sixteen lengths of 2 1-2 inch. These lengths are of the standard size, being 50 feet each, making the total hose carried 1,000 feet of 3 1-2 inch and 800 feet of 2 1-2 inch line.

There is a double supply of hose on hand at the slip which is wound upon reels and ready in case of emergency.

The two new boats, the "Thomas Willett" and the "James Duane," of a registered capacity of 9,000 gallons each, are equipped with two turbine pumps which supply two turrents and a water tower. The two turrents are surmounted by Glazer standpipes, as is also the water tower.

The water tower is a skeleton mast built up with four angle irons and lattice work. There is a 6-inch pipe passing up through the water tower, terminating in the standpipe.

The pumps on this boat are, as has been stated, of the turbine type. It has been found by experience that with this type of pump when the pressure required at a given fire runs above 150 pounds there will be a very large amount of slip. The pumps in a case of this kind should be staged, allowing the water to be forced from one through the other. The capacity when this is done will be reduced to about 60 per cent. of the available.

Where the High-Pressure System Comes In

In case of the water supply failing on shore the fireboats could take the water directly from the river and deliver it to the engines on land. In Brooklyn there are a number of places along the water front where the fireboats can be connected directly to the high-pressure mains in case of the failure of the water supply or of the pumps in the high-pressure pumping stations.

There are two high-pressure pumping stations in Manhattan and three in Brooklyn. One of the two Brooklyn pumping stations is in Coney Island. The locations are as follows: In Manhattan, one at the foot of Oliver street, and the other at the foot of Gansevoort street. In Brooklyn, one at Joralemon street, one on St. Edwards street and the other at Coney Island.

The two stations in Manhattan and the two in Brooklyn proper are equipped with electrically-driven centrifugal pumps, each one having a capacity of 3,000 gallons per minute. The two Manhattan stations have five pumps each, so that the two stations have a total capacity of 30,000 gallons per minute.

The Joralemon street station, Brooklyn, has five of these 3,000 gallon pumps and the St. Edwards street station has three pumps having a total capacity of 9,000 gallons.

The Coney Island station is driven by gas engines which operate three Goulds triple reciprocating pumps having a capacity of 1,500 gallons per minute each. This gives a total of 4,500 gallons per minute for the Coney Island plant.

In certain districts in Manhattan which are protected by the high-pressure stations the engines are not required to respond to the alarms. They are held in reserve. In Brooklyn, however, the signals are answered by the engines as well as by the hose carts and other apparatus.

The Brooklyn high-pressure stations start with a pressure of 75 pounds and the Manhattan with 125 pounds. This is generally sufficient for a small fire. In the case of a high building or a hot fire which cannot be fought at close range more pressure will be required. This is secured by notifying the pumping stations, which can, if necessary, give as high as 300 pounds. The Coney Island station being smaller will give as high as 150 pounds.

The largest high-pressure mains in Brooklyn are 20 inches, the smallest 12 inches. The hydrant pipes are 8 inches. The largest in Manhattan are 24 inches, the smallest 12 inches, and the hydrants 8 inches. In Coney Island the sizes run from 16 inches to 12 inches, with 8-inch hydrants.

The Question of Water Supply

An idea of the total capacity of the fire-fighting water supply in greater New York may be gathered from the total ratings of the three divisions considered: The steam fire engine, the fire fleet and the high-pressure system. The reasonable ratings of the different size fire engines, according to the National Board of Fire Underwriters, is as follows:

Size	Capacity
Extra first	1,000 gallons per minute
First	900 " " "
Second	700 " " "
Third	600 " " "
Fourth	500 " " "

If the fire engines are figured on this basis the total capacity of the pumping stations of Greater New York is 245,000 gallons per minute:

Manhattan and Bronx	65,000 gallons per minute
Brooklyn and Queens	49,000 " " "
Richmond	4,000 " " "
Fire fleet	68,500 " " "
All high-pressure stations	58,500 " " "
Total	245,000 " " "

This total, of course, is not of practical use and only a small percentage of the whole water supply could be concentrated in one locality. It may serve as a basis of calculation, however, in figuring the available supply of water from a per capita standpoint. The high-pressure mains it must be understood form an entirely independent system, having no connection whatever with the water for domestic service.

Now that we have considered the quantity of water which can be delivered by the three main divisions of the fire-fighting apparatus, that is, the rolling stock, the high-pressure pumping stations and the marine department, perhaps the next thing to take up would be the hydraulic principals involved in delivering the water to the points required and the methods in use by the municipal engineers in calculating the various quantities involved by the problems which present themselves.

Whether from a high-pressure pumping station or reservoir the water is conducted through the streets by water mains of various sizes. The sizes are, of course, governed by the requirements of the particular case. The material of the water mains and pipes in use in New York City is cast iron. The interior of the pipes are coated with a preparation to make them more durable and smoother so as to offer less resistance to the flow of water through them.

The Mathematics of Fire-Fighting

On leaving the pumping station or reservoir the water has a certain head which is utilized in two ways; first to give the fluid a certain velocity and then to overcome the internal resistance of the pipes to the flow of the water. The loss in head due to the frictional resistances of the pipe will vary directly as the length of the pipe line and the condition of the pipe, new pipe offering far less resistance to the flow than old pipe. This fact naturally brings up the old question of the life of cast-iron pipe.

The life of cast-iron pipe is governed by the thoroughness of the coating and the character of the water passing through it. The iron is attacked by the carbonic acid in the water which by a chemical process forms a depression in the pipe in which a little bunch of oxide of iron called commonly a tubercle is built up. Beneath this tubercle a rapid process of corrosion is continually going on. The process of corrosion will start in the most minute imperfection in the pipe coating and for this reason a most rigid system of inspection is necessary before laying the pipe. Well-coated pipe should last fifty years.

The sum of the loss in head due to the frictional resistance in the pipe and the head due to the velocity will equal the total head of the water at the point of entrance to the pipe line.

In figuring the size of pipe required for a particular case the city engineers make use of a table based on two formulæ given by H. Darcy; the first formula for velocities of flow less than 0.33 feet per second, and the second

$$h = \left(0.0198920 + \frac{0.00166573}{d}\right)\frac{l\,V^2}{d \times 2g}$$

, in which H = loss of head due to friction in feet; d = the internal diameter of the pipe; V = velocity in feet per second; l = the length of the pipe in feet; $2g = 64.324$; for velocities of flow equal to or greater than 0.33 feet per second. The method of procedure with Weston's tables, which are based on these formulæ, is as follows, for an example of this type: What size pipe will be required to supply Q gallons of water per 24 hours, under h feet head, the point of delivery being L feet from the point of supply, and the point of delivery having an elevation H feet below the head supplied? The loss of head in passing through the line must not be more than (H-h) in order to have the required head of h feet at the outlet. The table shows what size of pipe will deliver Q gallons with a loss of head equal to (H-h) feet. In case two pipes are necessary the amount Q will have to be divided between two pipes. The number of pipes used is as a rule a matter of discretion with the designer. Examples of other types are worked out in a similar way by the use of these tables. In New York City the ordinary hydrants may have a pressure anywhere from 75 pounds, which is attained in some parts of Brooklyn, down to a merely sufficient pressure to overcome that of the atmosphere. This will, of course, depend entirely on the locality. In designing the supply for a given vicinity the supply is designed to satisfy the requirements of the highest buildings in that vicinity, the amount required being based on previous experience in the supply of similar districts. This information is kept in tabular form.

The pressure on the high-pressure mains varies, as above mentioned, with the requirements of the case. The mains, hydrants, etc. are designed to take care of the maximum. The pipes of a given internal diameter are made in standard weights, the material used generally having a tensile strength of from 16,000 to 18,000 pounds per square inch. Different classes are being designed to meet different pressures and are used as standard weights for these pressures.

The water delivered from the steam engine pumps is calculated from the displacement. Assuming a double reciprocating pump with a stroke = 1, bore = d, the displacement of the plunger in gallons per revolution would be

$$D = 2\frac{(d^2 \times 3.1416 \times 2 \times 1)}{4 \times 231}.$$

From the quantity obtained from this formula would have to be subtracted the correction for the volume of the pump rod, as this is a large factor. There is a certain per cent. slip which must be deducted from the displacement in calculating the capacity of the pump. This percentage of wasted power, caused by the water getting past the piston, varies with the pressure and the make of the pump. It is large in the case of centrifugal pumps, there are none of these, however, on the New York steam fire engines in the land service.

The flow of the water through the hose is subject to the same hydraulic principles as the flow through the cast-iron pipes. There is a table published by the National Board of Fire Underwriters and supplied to every fire house which gives the gallons per minute discharged from various diameters of nozzles for any nozzle pressure. This table is for the best grade of rubber-lined hose.

A formula worked out from experiments by the New York City Fire Department expresses the gallons per minute for any case: $Q = \sqrt{p \times d^2 \times 29.7}$. Where Q = gallons per minute, p = nozzle pressure, d = diameter of the nozzle; 29.7 is the barometric pressure.

The following condensed table, showing the flow of water from a standard 8-inch hydrant under different pressure heads, will show capacities for the various pressures:

Head in Ft.	Ft. per min. vel.	Gals. in min.
.02	1.28	200
.06	1.91	300
.10	2.55	400
.16	3.19	500
.23	3.83	600
.31	4.47	700
.41	5.11	800
.51	5.74	900
.63	6.38	1000
.77	7.02	1100
.91	7.66	1200
1.07	8.30	1300
1.24	8.94	1400
1.43	9.57	1500

The Ever-Ready Automatic Starter

The production of an automatic device that will do away with the arduous and unpleasant work of cranking the automobile is as welcome as it is useful in a great number of cases. To have to climb more or less gracefully from the driver's seat to the starting crank of a stalled automobile accompanied by the shouts of a traffic policeman and the maledictions of delayed drivers of wagons and cars is a situation that nobody but the man who has been in it appreciates. This state of affairs becomes all the more acute when the unfortunate happens to be a woman trying to overcome a 40-pound compression with a 30-pound pull.

The Ever-Ready Starter is designed to be of use in starting the motor at any time, whether it be stalled or in starting for the run. It can be attached to any automobile or motor boat and is guaranteed to start the same by a simple pressure on a pedal or lever which releases the brakes which hold the mechanism and automatically cranks the motor.

In appearance the starter is very much like a reversed automobile headlight, being about the same size and of polished brass or other finish as may be desired. It is placed on the front of the car at the point where the starting crank is generally placed.

The operation of starting is performed by two powerful springs which are strong enough to spin the motor for about six revolutions against compression at the rate of about 300 revolutions per minute. These springs are wound up by the motor itself during the first twenty-six revolutions made after the engine has been started. When the springs have been fully wound an automatic release comes into play and disengages the winding mechanism from the driving shaft, leaving the starter ready for the next time it may be called upon to start the motor.

It is, of course, understood that the engine must be in condition to start, the same as if it were to be started by hand. In case the starting spring is released without the spark switched on or some other condition of starting left unfulfilled, the starter will have to be wound by hand. A crank is provided for that purpose and a system of reducing gears makes it very easy to wind up to the proper tension. In case the starter is disabled by collision or through some other accident which renders it inoperative, the front cover can be removed and the regular starting crank which was furnished with the car may be used until the needed repairs are made. The device is guaranteed against defective parts for one year.

Owing to the rapidity with which the engine is turned over in starting, the magneto may be used immediately. There is a device by which the starter may be disregarded and the engine turned over slowly for grinding valves or timing the engine.

One of the greatest arguments in favor of a device of this kind is the list of accidents which are directly traceable to the cranking of automobiles by hand. The effect of a "kick-back" cannot be foretold and is often disastrous. Many women are also kept from driving their own machines because they are utterly unable to crank them and cannot in all cases keep a chauffeur.

Agent: "Let me see; you ordered a car from me some time ago, did you not?"

Victim: "Yes! I believe I did. If it is all the same to you I will be willing to change that order to an entreaty."

* * *

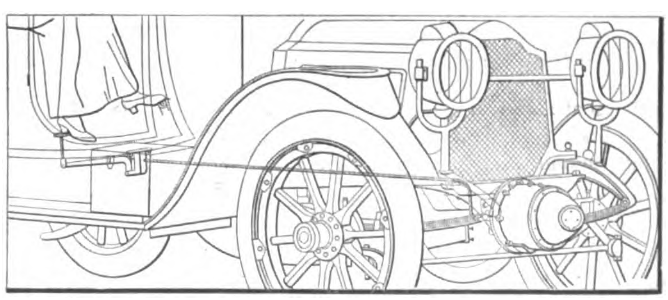
"Your Honor," said the attorney, "I propose to show that this prisoner stole ten inner tubes out of the locker of my client's car."

Judge: "So! How do you propose to make a case out of ten inner tubes?"

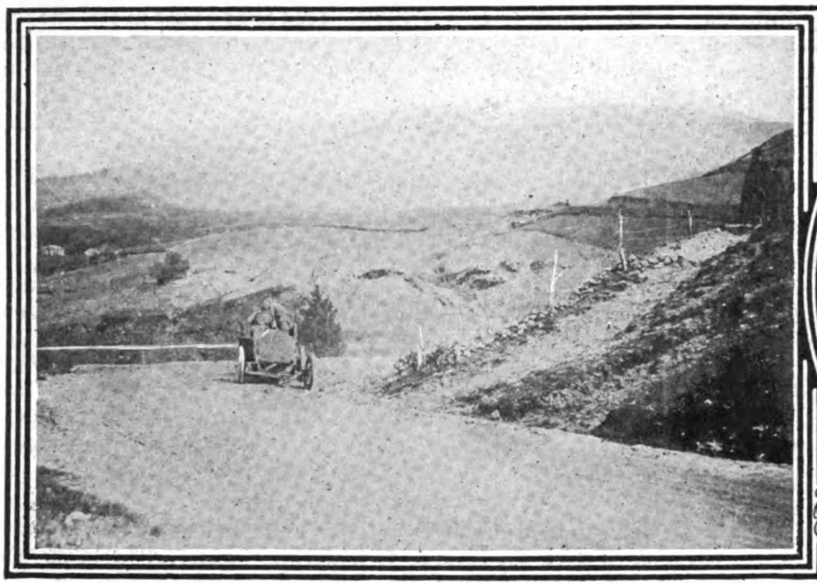
* * *

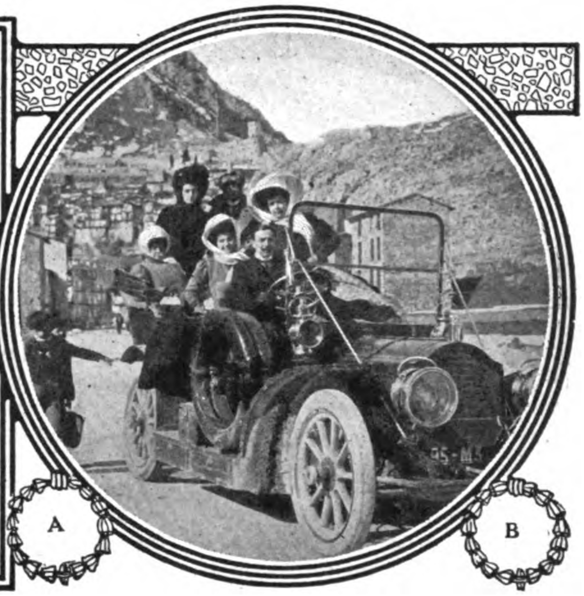
Observer: "I see that the widow of old Moneybag married her chauffeur!"

Companion: "Yes! I suppose that she had to do something to keep the money in the family!"



Illustrating the installation of the Every-Ready Starter on a town car





A—Hair-pin turns are met at frequent intervals on Sicilian roads B—The author and party after descending into one of the beautiful valleys

Word-Picture of a Sicilian Tour

Describing Some Beauty Spots of the Lovely Island

E. B. Row graphically describes a most enjoyable trip he recently took through the island over which Mount Etna towers in awful grandeur, but which Nature, possibly in recompense for the woes visited upon it in the past, has endowed with a beauty which makes it famous throughout the world.

IN the seventy-odd thousand miles of touring through Europe in an automobile, none of the territory has so appealed to me as the trip just completed around the pretty island of Sicily.

Everywhere there meets the eye a continuous riot of color, with stupendous masses of mountains that overlap each other like the waves of the ocean—mountains everywhere, with lovely valleys in between and no level land, with Etna reaching out into the sky, a dome of dazzling snow towering above all other peaks.

As you skirt the eastern border of the island you run over beautiful roads, narrow but as smooth as the Cornichie on the Riviera. You pass through town after town with towers, castles, bluffs, capes and high-topped headlands with rocky promontories and sweeping curves of shore line, all coming into view like a stately procession. To each curve of the coast there is an answering curve of beauteous sea with hundreds of indentations, needle points and forelands of rich and glowing hues, brown, red, purple and violet.

The cities furnish endless quays bordered with snowy palaces in white stone, sickle-shaped harbors, shelving terraces and exquisite vistas of cape and bay. I wish it were possible to picture the foam of the white sea surf beating against lava cliffs with the deep blue tinting of the hills and ever-varying mountain lines that wander heavenward and then sweep gracefully to the sea.

A gem of an island, and with such a history! Gods and demi-gods, heroes and nymphs, nereids, Moors, Sicilians, Greeks and Romans, invaders from every land, in all ages and since all time, each race leaving the traces of its conquests in stone. In Messina all that was left standing after the earthquake was the cathedral.

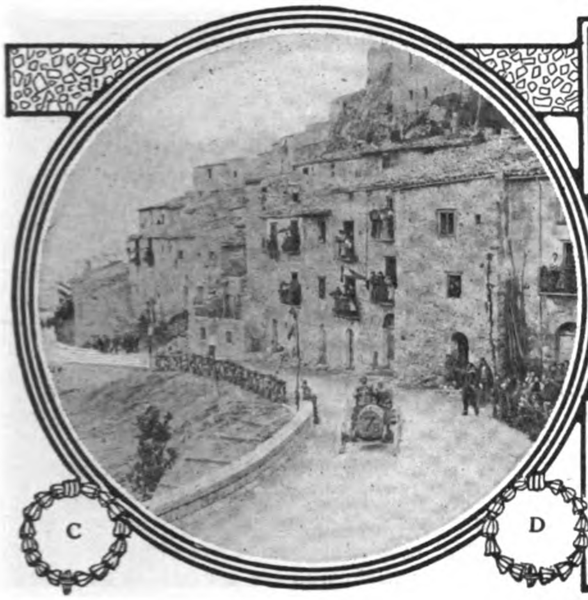
The gods have done much for this city, and as long as mountains and sea, sun and sky hold together, it will always be beautiful. Somehow there is an air of innate loveliness one can recognize in a city, as in a woman. Messina has it, while her shipping lends a tinge of cosmopolitanism.

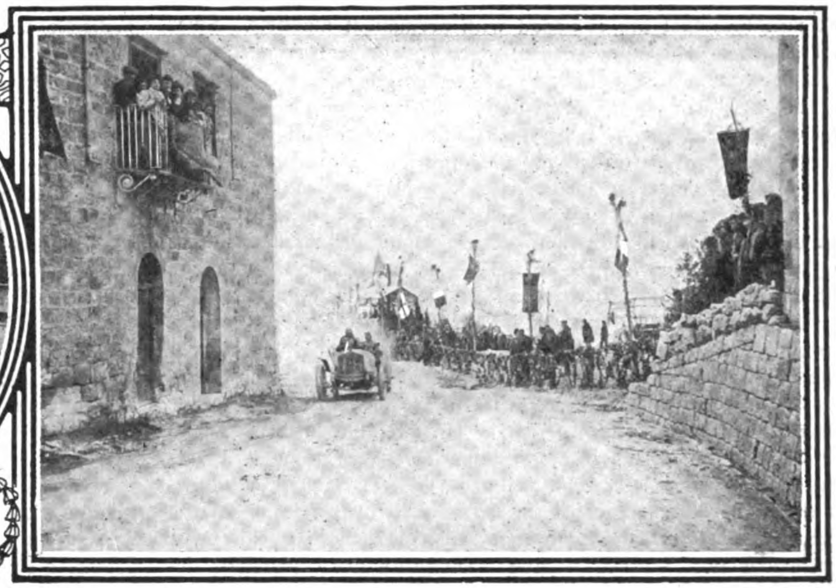
Leaving Messina on the north, you drive over pretty roads, rounding capes and promontories where the blue sea breaks against low rocks, the waves swarming upwards in sheets of curling foam, which mark the outline of delicate bays. Every yard of the highway is historic ground and the home of classic mythology. Every sandy baylet, river, rocky point and headland has its legend.

For over forty miles we drove our Packard in sight of Etna on the north, a wonderful giant, three miles high, the monarch of volcanic life and action. Forests of cork wood, olive, lemon and orange groves encircle its sides for seventy-five miles like a green belt; above this comes the snow line, a mile in width; around its craters all is dead, with lava boulders and streams of blackness flowing from every side.

Taormina is the picturesque city on this end of the island, a pretty spot lying nearly a thousand feet above the sea. From here you visit Etna, whose white flanks sweep down into fertile valleys, dashed here and there by a blackened lava stream. There castles, towns, convents, churches on every height, groves of fruit and vineyards glowing in pretty colors in the transparent atmosphere, while high above the volcano cuts the sky as sharp as steel and steamy clouds from the craters fill up the picture.

At the foot of Etna lies one of the finest harbors in the world, destroyed by lava with ninety thousand of inhabitants, the old city of Catina. A wall of lava forty feet high fills up the port and runs out to sea beyond the entrance of the harbor. Etna is noted for its wine, and vineyards clothe the hillsides on every hand.





C—The mountain sides form a natural grandstand on race days

D—Interested spectators in the Targa Florio race which is run in Sicily

While in this section no one should fail to visit one of the largest monasteries on the island, where below the church are placed the tombs of the departed. I looked into this burial place where, arrayed in their vestments, all classes of people, dried and set up against the wall or held in niches, or laid to rest in their caskets, are exposed to the view of the visitor. In one velvet-lined trunk was Cardinal Gibonois; next came Count Conrad, son of the philosophic Frederick II; then came Alfonso the Magnificent, King of Naples and Sicily; also many people of Norman line and a royal woman whose name I forget. Here they all rest like passengers in a free berth on a quiet sea. Here are bishops by the score, priests without number, individuals of every station in life sitting or standing for centuries.

The next large city towards the east from Catina is Syracusa, the largest of the Greek ports, and strong in its natural position either by land or sea. From every quarter of the globe enemies came to this city, taking this place as a landmark for invasion.

The Catholic cathedral here is built over the shrine of Minerva, and some of the Grecian columns mark the side of the church. Of the temple of Diana only little of the marble remains to mark the spot of this once beautiful structure.

All the Sicilians in the country places proved friendly and even cordial. They keep many dogs, which they seem to love as much as their babies. We stopped in mountain cities and were well entertained, the food being very good, but the luxuries in sleeping apartments are apparently not understood.

Sicily is Greek, Doric Greek, as seen in every ruin and temple, some structures still perfect, with no stone missing.

The colors of the sea are marvelous. As you follow the shore line you see blue of every tint, azure running into reds and browns, buff, cream and yellow with sheets of foam that look like lace-work on the pretty shores.

Short Stories of Current Interest

Unraveling the Puzzling Situations

As the art progresses certain apparently unanswerable questions recur, but when the irrelevant matter is eliminated it is not so difficult to get at the facts and arrive at a fitting conclusion.

IN the discussion of the lubricating problem as it is being presented in The Automobile from time to time, there is an apparent attempt on the part of those who, for one reason or another, cannot well use a lubricator, to show that this device is not essential to success and that simplicity is duly represented when the lubricator is dispensed with, provided only that some lubricating oil is placed in the gasoline tank where it is supposed to be dissolved, and after it flows out of the gasoline tank through the carbureter into the crankcase of the motor it is supposed to re-collect the scattered remnants and to present itself in force at the portals of the bearings, where, after knocking for admission, it is bowed in and permitted to do the lubricating work of which the bearings have enough and to spare. One enthusiast, in decrying the idea that an unbroken film of lubricating oil is desired between the journal and the box, went so far as to build a testing equipment on the electrical principle for the purpose of showing that lubricating oil does not present an unbroken film, for, as he states, since lubricating oil is said to be an insulator, should it form an unbroken film the resistance would be so high that an electric current would fail to pass. We do not know whether or not this test shows that the particular lubricating oil used in the experiment is suitable for lubricating purposes in automobile work, but if it is the test as conducted shows that it was not an insulator. If, on the other hand, the test shows that there was no evidence of an unbroken film, it may be taken for granted that the lubricating oil was not of a suitable quality for this class of work.

LIGHTING dynamos are coming into vogue and present practice is somewhat divided between the types of generators that are provided with an electro-magnetic field and the makes of machines that are equipped with permanent magnets. Since all of these generators have to deliver a direct current for the purpose of charging a storage battery they must be provided with a commutator, and the first difference that a user of an automobile must appreciate is the fact that the average magneto as it is used in ignition work is not equipped with a commutator, but it has a collector ring instead, and the current delivered therefrom is alternating in its characteristic. Since lighting dynamos as they are used in automobile work cannot deliver current for lighting purposes when the engine is shut down, it is the function of the storage battery to supplant the lighting dynamo during the period of engine inactivity, and it remains for the lighting dynamo to charge the storage battery as well as to furnish current for the lights when the engine is running.

One of the serious problems lies in the lack of ability of the average small generator to deliver current at a low speed, and this, in the face of the fact that automobile engines when operating under average conditions run at a relatively low speed, makes it necessary for the user of the car to watch the relation of the generator to the storage battery and to make sure that the battery is not "starved." Some generators are capable of delivering the full charging current at approximately 1,200 revolutions per minute, but it is unfortunate perhaps that quite a number of them deliver but a feeble current at this speed.

When the lighting equipment is new and the storage battery is in good working order it is more than likely that a poor generator will fail to show its weakness, but as the battery tapers off in capacity, and a condition of persistent sulphation arrives, the generator will fail to supply the need and the state of unbalance existing will become only too apparent to the owner of the car. In the purchase of a lighting equipment it is wise to observe the lowest speed at which the generator will furnish the full charging current for the battery, and it is also desirable to observe whether or not there is undue sparking at the brush tips as they contact with the commutator, this being evidence of overwork or a bad state of design of the generator. The practice of looking at the lights to see how bright they are and of judging of the capability of the lighting equipment based upon the illuminating properties of the lamps is bound to lead to a few heartaches on the part of those who are so readily convinced.

WHEN the engineering department of an automobile manufacturing company spends days and nights for months and months in search of the means for silence of the product it is spending money which the purchasers of cars will have to furnish, and it is worth while doing so if the object sought after is gained. But when the automobiles are finished and they are placed before the discriminating eyes of the purchasers it will be too bad if the side-doors of the body are so loosely hung that they will continuously rattle, and it will be a great shame if the mudguards are fastened to the irons by means of flimsy stove bolts. The methods in vogue in many plants are such that the engineers who go in quest of silence have little or nothing to do with the body work, and this plan in the face of a certain type of conceit that finds lodgment in the being of the body-builder makes it easy to see how more than 50 per cent. of all the noise can readily come from the part of the equipment that the engineer has nothing to do with. Fortunately, noise is a condition that the average purchaser can testify to if it exists in a given make of car, and if the builders of automobiles continue to tell purchasers how silently their products perform they may expect that the time will come when these purchasers will take their word for it and govern themselves accordingly. Fortunately, too, it will be quite an easy matter to hang doors in bodies so that they will not rattle, and as for encouraging the makers of stove bolts life is too short.

HABIT gets in the way of every reform that is undertaken, and the man who has acquired all of the refinements of a first-class habit is willing to swear that it is founded upon a true principle and has right as its mainstay. In the meantime the habit of putting a battery box on the runningboard of an automobile, like the habit of placing the tires in a sling so located as to prevent the driver from getting into the car, is like the habit of placing the headlights on brackets at the front ends of the side bars so exposed that they have to do a double duty, but they serve but poorly as bumpers when the occasion requires. When automobiles were first made the designers thereof were actuated by a certain enthusiasm and they promised so much for their wares that it never occurred to any user that he would have to equip himself with tools for the purpose of making roadside repairs, hence no provision was made in the original designs for the storage of tools.

In the same way not a few tiremakers thought that their "pneumatics" would last for a long time, and the idea of taking along a spare tire was an after-thought dictated by experience on the part of users of automobiles. In the meantime, purchasers acquired the habit of buying cars as they looked standing upon the salesroom floor before the tool box and the spare tires were mounted into position, and the pleasing effect produced really had nothing to do with the appearance of these cars after they were loaded down with junk before they were put into service.

The builders of bodies are beginning to realize the necessity of making provision for the storage of tires in a covered position, and the thought is coming to the front that there should be a compartment for tools. Moreover, there is a splendid opportunity for some bright mind to think out a form of tool compartment that will have a place for everything necessary, and that will keep it in its place without rattling. In the placing of lamps the newer form of flush (electric) lamp is being commented upon favorably, and it is now believed that bodies can be so made that there will be room for everything essential to the success of a tour without detracting from the comfort of the owner of the car and the guests whom he might be pleased to take along.

May Happen to Anyone

There are times on a tour of any length when a cool head and a knowledge of what to do under the circumstances are of invaluable assistance to the driver, be he professional or amateur. A hint which is the proof of experience may be of use.

AN affair of frequent occurrence in general driving is the ascent and descent of steep and slippery hills. Obviously, in descending, the brakes must be used in order to keep the car under control, but the autoist often finds that their application causes the rear of the car to swing around, particularly if one hub-brake has a better grip than the other. With smooth tires, that is, tires without studded treads or unequipped with chains, the situation is hazardous despite anything the autoist may do, but in all cases such hills should be approached at a walking pace and the car prevented from increasing its speed by judicious use of the brakes the whole way down. Equally awkward is the ascent of a hill thickly coated with mud. In such case, once the wheels commence slipping the car may tend to spin in a circle and to slip backwards while so doing to the bottom of the hill. If the hill is extraordinarily steep and greasy, several circles may be described if the car is small or has excessive clearance, and the autoist will not have the slightest control over the car during the evolutions. In climbing ordinary hills that are greasy, a moderate speed should be maintained from bottom to top, avoiding any sudden acceleration of the road wheels, and momentarily easing off the drive to enable them to regain their hold at the first signs of excessive spinning. The ability to drive at a constant speed is invaluable to the autoist in cases like this. Where ascents or descents are hazardous, rope wound around the tire and felloe is often an invaluable aid.

When Judgment Whispers Don't

A Series of Abbreviated Injunctions

It is suggested that common sense and uncommon dollars are congenial to each other, and through force of habit occupy well-cushioned seats in the same chariot.

DON'T look for a rich farmer on a bad road.

DON'T look for a bad road in front of a rich man's residence.

DON'T object to the improvement of roads just because you are not the possessor of an automobile.

DON'T forget that your income may be traced to automobile activity.

DON'T sit in the Senate if you are so stupid that you bark at the automobile fraternity.

DON'T undertake the futile task of proving that you are an intellectual if you legislate against the third industry in the world.

DON'T fail to resign your position in the Legislature if you examine yourself on a dark night and find that you are an incompetent.

DON'T delay action just because you fail to see the point—the public will understand it if you don't

DON'T advocate that the residents of the penitentiary make clothes for you to wear—they can be placed to better advantage fixing the State roads.

DON'T permit States' prisoners to compete with honest workmen in the industries—road-building is a much more healthy occupation for prisoners.

DON'T fail to request your representative in the Legislature to make some provision for the maintenance of roads.

DON'T overlook the fact that road-building represents a waste of money if no provision is made for the maintenance problem that follows.

DON'T eschew political activity on the ground that you are too immaculate to rub elbows with the type of politician who would rather see you vote from a cemetery than elsewhere.

DON'T let political grafters run your business for you—do you think so much of them that you would place them in your own office?

DON'T fail to appreciate the fact that every politician is working for you whether you like it or not.

DON'T forget that some politicians give two licks for themselves for every lick they give for you.

DON'T take your automobile over a bad stretch of road without making a complaint in writing to the president of your club.

DON'T belong to a club without advocating that its members go in for good roads.

DON'T try to usurp the functions of the officials of the club to which you owe your allegiance.

DON'T forget to nudge the officials of your club if they go to sleep.

DON'T fail to appreciate the difference between co-operation and the action of a disorderly minority.

DON'T be discouraged if you fail to get action the first time you bring an important matter to the attention of the club officials.

DON'T act with impatience in the face of an important emergency—success follows in the wake of calm and deliberate presentations of good arguments.

DON'T try to have your own way unless you can at least prove to yourself that it is a good way.

DON'T expect others to approve of your way if you cannot approve of it on your own account.

DON'T run around in an automobile without knowing anything about speed laws.

DON'T forget that law is supposed to be based upon common sense as well as upon precedent.

DON'T fail to display a fair measure of common sense if you are short of legal lore.

DON'T try to become a curb-stone lawyer if a policeman makes a few pointed inquiries about the speed at which you were driving your car.

DON'T try to convince a policeman that you were going backwards if your car was picking up the road in the opposite direction.

DON'T object to reasonable police regulations, even if they do differ from each other in the towns that you pass through in a day.

DON'T forget that the citizens of each township have the happy faculty of understanding their own local situation in a manner satisfactory to them.

DON'T forget the old adage "When in Rome do as the Romans do."

DON'T toil with ignorance—learn something about the mechanisms in your automobile.

DON'T act like a star of the first magnitude when you meet a farmer on the roadway—he may have a little star factory of his own.

DON'T mistake egotism for power; the egotist stands in front of a mirror; the man of power has a strong stride, but he never gets out of breath.

DON'T fear your self-appointed enemies; they are more scared of you than you can be of them.

DON'T be eddied out of the main current—your franchise is good; use it.

Vanadium in Steel

Describing the process to be followed in testing a sample of steel in order to ascertain if vanadium is present therein, and in what quantity. By this test it is said to be quite possible to detect as small a vanadium content as 0.01 per cent.

A RAPID chemical method for ascertaining the presence of vanadium in steel is based on the fact that a brownish-red coloration is displayed when vanadium salts are acted upon by peroxide of hydrogen. The method of making the test is as follows: Dissolve 0.25 gram of the steel to be examined in 4 cubic centimeters of nitric acid of density 1.20; heat; add about 0.3 gram of persulphate of ammonia. There follows a discharge of gas. Heating is continued until this discharge ceases. Then the solution is cooled. There is added 3 to 4 cubic centimeters of phosphoric acid of density 1.30. The yellow coloration due to the iron ceases and the liquid remains only faintly rose colored. Shake. By means of a pipette 3 to 4 cubic centimeters of peroxide is poured into the test tube slowly so only thin films of the two liquids are mixed at the point of contact. In the zone of contact there is now formed, if vanadium is present, a brownish-red ring. As little as 0.01 per cent. of vanadium can be detected by this method. By comparison with samples of steel whose vanadium content is known, and which are treated in the same manner, the vanadium content can be approximated.

Facilities for the Hardening Room

Quenching Baths and Their Accessories

E. F. Lake discusses quenching baths for the hardening of steel and makes comparisons for the benefit of the man who must obtain results, giving quenching temperatures and simple rules for the governing of the process, illustrating the points that are uppermost in the story.

A GREAT deal of attention should be paid to the baths in which to quench steels when hardening. This is of as much importance as the degrees of temperature to which steel is raised or the constitutional changes that take place. The rate of cooling is not instantaneous and consequently is not swift enough to secure perfection. Thus the intermolecular transformation will be more or less incomplete, according to the rate of cooling; the better the bath the better the results that are obtained.

Many different materials are used for quenching baths, and the more common are enumerated below according to their intensity on 0.85 per cent. carbon steel: Mercury; water with sulphuric acid added; nitrate of potassium; sal ammoniac; common salt; carbonate of lime; carbonate of magnesia; pure water; water containing soap, sugar, dextrine, or alcohol; sweet milk; various oils; beef suet; tallow and wax.

As the conductivity and viscosity of these baths varies greatly with their temperature they do not act under all conditions with the same relative intensity. The curves of intensity are therefore very irregular and cross each other frequently. With the exception of the oils and some of the greases the quenching effect increases as the temperature of the bath lowers. Water at 60 degrees will make steel harder than water at 160 degrees. Sperm and linseed oils, however, at all temperatures between 32 and 250 degrees F. act about the same as distilled water at 160 degrees F.

The influence of the bath depends upon its nature, its temperature and its volume, or, in other words, on its specific heat, conductivity, volatility and viscosity.

The specific heat of the bath is an important factor, and yet but little attention is paid thereto. The more rapidly we cool a high carbon steel from 1650 to 200 degrees F. the more effective will be the hardening process, these being the temperatures at which the transformation corresponding to the hardening process begins and ends.

When a bath is constantly used the first piece quenched will be harder than the tenth or twentieth, owing to the rise in temperature of the bath. As soon as the heated metal is plunged into the bath the liquid begins to heat. The number of calories necessary to raise the liquid's temperature a certain number of degrees will be the greater the higher its specific heat. A bath is the more active in proportion as its specific heat becomes higher. The less rapidly the equilibrium is established between the hardening bath and the metal quenched in it the more active will be the bath.

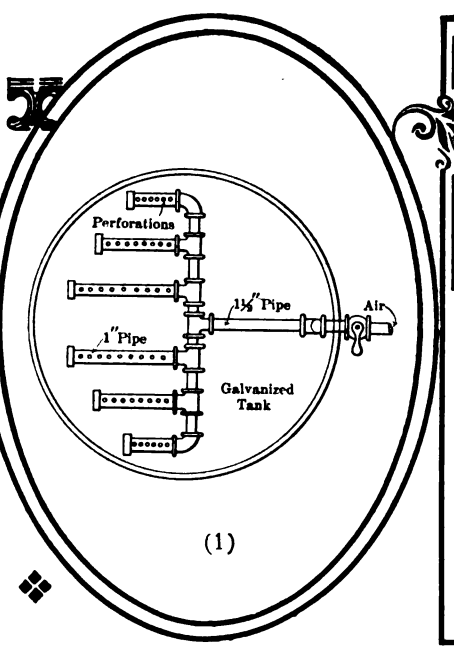
Mercury has a much lower specific heat than water, and quenched steels are cooled nearly three times as rapidly in water as they are in mercury. The hardening effect is therefore much lower than that of water, but surface cracks and fissures are not nearly as liable to occur.

As steel is plunged into a liquid that volatilizes easily at the high hardening temperature a space is formed around the metal that is filled with vapor, and this retards the further cooling action of the liquid. To overcome this it is necessary to either keep the piece moving around in the water or keep the bath in motion so that these vapors will be thrown off and fresh liquid be continually brought into contact with the metal. This continual motion effects the exchange of heat between the piece being hardened and the bath, and the greater the conductivity of the bath the more quickly the metal cools. The viscosity of the bath has an influence on the phenomenon of convection, which is the principal means of the exchange of heat; the higher the viscosity the less its hardening effect.

The mass of the bath can be made large, so that no great rise in temperature occurs when continually cooling steel pieces. If the rise in temperature of the bath can be properly regulated it can be made small and this rise in temperature be made useful when hardening parts that should remain fairly soft. It would thus save the time used in reheating and tempering the piece later and largely overcome the liability of its cracking or checking when quenched.

Another way of arriving at the same results would be to use a double quenching bath. In this process lead or salt is often used and maintained at a certain temperature. The piece is quenched in these until it reaches their temperature and is then removed and quenched in a cold bath or cooled in the air.

The baths which give the best results are those in which the temperature is always kept even. If considerable time elapses



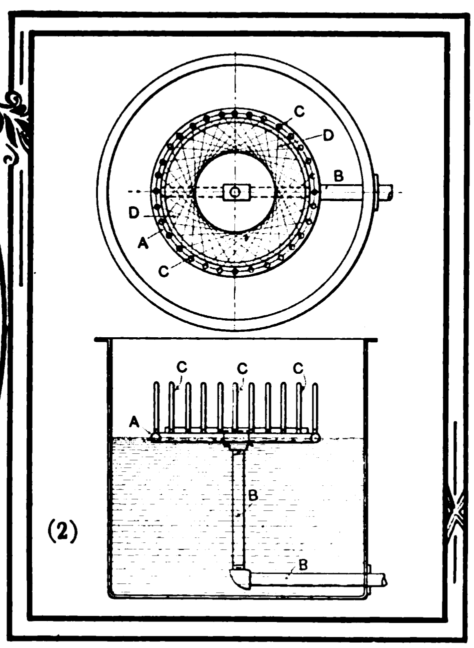


Fig. 1—Showing the method of piping in the bottom of a quenching tank for the distribution of the air that is proposed for the agitation of the bath
Fig. 2—A spraying type of quenching bath for use in the hardening of steel

between the quenching of different pieces the bath will retain an atmospheric temperature from its own natural radiation. When a continuous quenching of pieces is necessary some mechanical means must be provided. The bath must either be very large, so it will keep cool from natural radiation, or the liquid must be kept flowing in and out of a small bath to keep it cool. Better results can be obtained from the small bath cooled by mechanical means, as its temperature can more easily be regulated and kept constant.

One method that gives good results on certain kinds of work is the spray that is thrown from a circular gas pipe with perforated upright pieces, as shown in Fig. 2. In this A is a circular gas pipe into which are screwed perforated upright pipes CC and intake pipe B. Water coming through perforated pipes CC forms a spray on lines DD.

Another method is to place pipes in the bottom of the bath, as shown in Fig. 1. The liquid is pumped through these and allowed to overflow at the top.

Another method is to surround the tank with a perforated sheet and pump the liquid through these perforations. Some baths of this nature have been fitted up with a conveyor that carries the pieces through the bath and drops them into receptacles placed at the other end.

The Search for Silence

With the disappearance of noise from the motor, those other members of the chassis whose noisy performance was formerly drowned in the motor's din, have become prominent disturbers of the motorist's equanimity, which presages, among other possibilities, the more general adoption of the worm drive and a substitute for the live rear axle with its loose joints.

NOISE as it is being taken out of the motor uncovers the noise that has always resided in the chassis, and the coming of the silent types of motors has brought designing engineers to a realization of the fact that what they call silent performance in the chassis amounted to a positive din. In the meantime, purchasers of automobiles have been preached to about silent performance until some of them have been persuaded to believe that their noisy machines were silent and that noiselessness is the first requisite in the operation of an automobile. Under the acute conditions of to-day it costs more money to get noise out of an automobile than it does to build the car. Where this search for silence will end it is difficult to say, but the fact remains that quite a number of automobiles are unduly noisy because of the use of stove bolts in the holding of the mudguards and in the employment of other flimsy pretexts that have no fitting place in the makeup of an automobile. In the meantime, it is pointed out that some of the most approved practices of the present day are at variance with the necessities from the silence point of view, as, for illustration, a full-floating live rear axle has a number of loose joints in its make-up, nor would it be a full-floating live rear axle were these loose joints done away with. How to drive through a dog and maintain a condition of silence is one of the problems that engineers have to cope with, and if the search for silence continues, becoming more acute than it is today, the live rear axle and the dog drive will certainly have to make way for the type of fits that do not depend upon lost motion. The best argument in favor of the worm drive is that of silence, and the probabilities are that the search for noiseless performance will bring the worm drive into general use to the entire elimination of the bevel drive. It is not claimed that the efficiency of a well-made worm drive is quite up to 95 per cent., and few indeed are the engineers who will make so brave as to claim that a bevel drive has an efficiency of more than 95 per cent. It was not so long ago when one automobile-building concern claimed that in the search for silent performance it had to discard 55 per cent. of all the bevel gears that were turned out in its plant, and the wildest flight of the imagination is insufficient to make one believe that any such poor luck would attend the building of worm drives.

Labor-Saving Device in the Testing Shop

In days of large production such as the present every conceivable means is devised in the shops to save the men unnecessary labor. It was no common occurrence a few years ago to see motors being carried by two or three men from one part of the shop to the other, but such laborious methods no longer exist. Either a traveling crane is used or the motor is placed on a truck which runs on rails, and by the aid of turntables it can be transferred from one shop to the other. That is all very simple and the next operation after the fitting cannot be regarded as hard work. This consists of "running the motor in" by means of a belt, using the flywheel as a pulley off another pulley of suitable dimensions attached to the ordinary shafting. This operation may last for several hours, according to the motor; but when it arrives in the running shed and is run under its own power for several hours and the different parts adjusted, the tester is usually given the task of starting the motor in the usual manner, *i. e.*, with a starting crank. To do this once or twice is no hardship, but when he has six to one dozen motors to test and they have to be stopped, say, every half-hour or oftener, the amount of manual labor that the tester has to perform is infinitely greater than the testing operations themselves. Besides, he soon becomes tired, and a tired man cannot be expected to furnish the same good work as a man who is fresh. In order to overcome this a means was devised in the Everitt plant in Detroit, whereby all manual labor in starting was done away with. With an electric motor on wheels, as shown in the illustration and a pulley attached to the main shaft, a belt can be slipped over the flywheel of the motor to be started. The electric motor is then started, the current being furnished from main leads and a length of flexible cable can be fitted into one of the several plugs in the wall. The tester then gently pushes the truck forward along the rails and as the tension of the belt increases the motor is started. It is an easy matter to throw the belt off the flywheel. The illustration shows only three motors, but in reality there is often room for twenty at a time along the line.

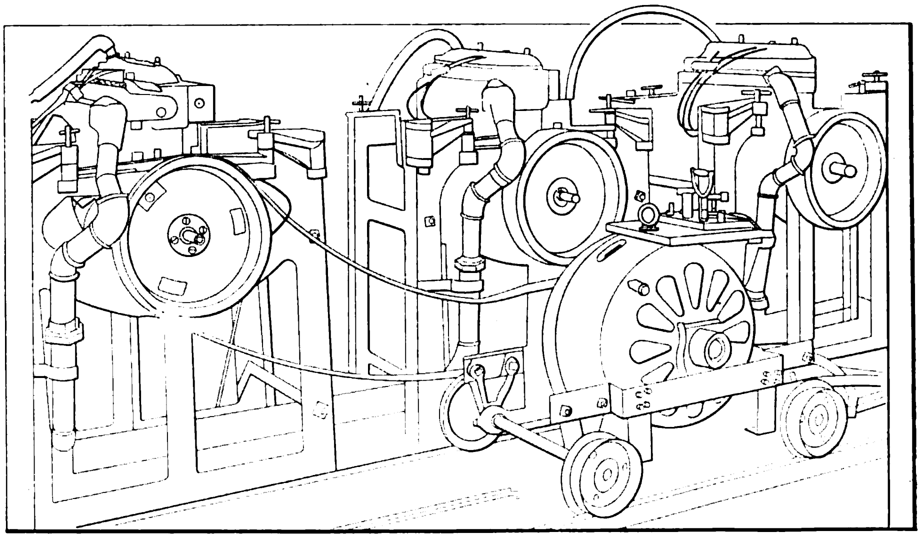

Fig. 1—Method of starting motors in the Everitt testing shop by means of an electric motor and a belt

It Stands to Reason—

(When Common Sense Sits Alongside of the Driver)

THAT tires are made of that strange substance called rubber in combination with a frail fabric called "cotton" no matter how carefully they are made, and long life is only to be experienced if the automobile is driven at a slow rate of speed when the roads are bad.

THAT long life of the tires will not fall to the happy lot of the automobilist if high speed is indulged in when the mercury in the thermometer soars to high levels.

THAT over-inflation is too much feared by the average owner of an automobile, and it is scarcely to be supposed that a puny tire pump will be guilty of any such crime in any event.

THAT under-inflation is the common disorder that besets tires at every hand.

THAT a tire-gauge is the only sure tell-tale available to the man who desires to operate his tires at a predetermined pressure.

THAT even a tire gauge accompanied by a poor pump in the hands of a lazy chauffeur will fall short of its intended purpose.

THAT the lazy man may not be a chauffeur after all.

THAT any amount of pressure will be of small avail if the tires are too small for the work that is assigned to them to do.

THAT the purchaser of an automobile should decline to take a demonstration from the maker if over-sized tires are used on the demonstrating car, provided they are not used on the car that the purchaser is to get.

THAT tires indicate their lack of proper size if they cannot be inflated to roundness under the load that they have to operate with.

THAT tires will creep in the rims if they are not properly fastened and no end of trouble will result.

THAT a tire lubricant, such as talcum, should be used between the tube and the case to prevent chafing of the walls of the tube.

THAT tires will be eaten up by mildew if the rubber coat is punctured and water is permitted to get at the cotton of the fabric.

THAT rubber is used as a seal to prevent mildew from getting at the cotton of the fabric as well as for other purposes.

THAT the average automobilist fails to appreciate the enormity of the appetite of a few million mildew "bugs."

THAT rubber, in addition to sealing up the fabric, shows a certain strength besides binding the layers of the fabric into intimate relation to each other.

THAT the tread of the tire, since it must serve as the buffer between the roadbed and the carcass, is made of a toughened compound that will only adhere to the carcass if it is carefully put on.

THAT the carcass and the tread should be kept welded to each other all of the time.

THAT tires will give out more rapidly when the weather is warm, due to the fact that rubber loses much of its strength at high temperatures.

THAT driving the automobile at a low rate of speed is the proper thing to do when the weather is warm as well as when the roads are bad.

THAT putting on the brakes too suddenly will produce skidding and a high rate of tire depreciation.

THAT good driving cannot be measured by the number of times the brakes are suddenly applied.

THAT going around a corner on two wheels may be picturesque, but the tire bill resulting can scarcely be viewed with equanimity.

THAT an automobile will make the greatest possible distance in a given time if it is driven at a uniform rate of speed.

THAT storing an automobile in a garage where the floor is coated with grease adds to the cost of storage to the extent of at least four tire cases per month.

THAT standing an automobile out in the glare of a summer's sun is the best way to help the tire maker broach a watermelon.

THAT high-speed work when the road is wet and jagged rocks abound is another way to keep the tire maker out of the poorhouse.

THAT the tire maker is already too busy, and it is unnecessary to burden him with the making of extra tires for no better purpose than to furnish replacements to the type of man who would not know common sense if he saw it coming down the road.

Long-Distance Touring in Australia

Recounting the difficulties experienced by a party of automobile tourists in Australia, where it is sometimes necessary to keep a sharp lookout to avoid missing the road. Sandy wastes abound in some sections, and if the travelers lose their way, it means a long delay, and possibly worse.

THE ride just concluded by a party of prominent Australian automobilists from Adelaide to Sydney was full of interest. They passed over many pleasant stretches of Nature's highways, many of them unimproved. One of the interesting runs covered 92 miles, between Kinkston and Meningie, which occupied a day. But at all times one needs to look well ahead, for to lose the road means a series of difficulties and maybe mishaps. Take, for example, the Coorong, a cheerless waste, where mighty sand drifts choke the roadway. Some of these drifts rise to a height of 87 feet, while heaps of from 7 to 10 feet high are common barriers. When practically lost amid these sand drifts, the automobilist finds it very difficult to make a long detour. He is obliged to watch for the proper divergence by means of which he can shoot his motor car through into the region of roads again. Sometimes it happens that the automobilist misses the longed-for deviation path, owing to scant evidence of travel. At such periods he brings his car to a standstill, hard against a forbidding ridge of sand. The result is that when the wind blows the automobilist "grits his teeth" in good earnest. Recently a party of motorists lost their way while casting about in the sand and they had quite given over to despair when a horseman hove into sight who piloted the car along a crooked route, thus enabling the party to reach Miningie as the night closed in.

LONDON, ONTARIO, has adopted the motor car method of sprinkling the streets. The City Fathers have put two automobile sprinklers into commission, thereby saving $14,000 annually, as compared with the horse-drawn watering cart service. It is proposed to install two more of these sprinklers, doing away with horse-drawn vehicles for this work altogether.

How to Improve Harsh Suspensions

Hints on How to Secure an Easy-Riding Car

The question of the suspension of cars is dealt with in a recent issue of "La Vie Automobile," by André Guetet. The action of the springs is considered in some detail, and the necessity of paying attention to the centering of the superimposed masses is also explained.

IS it possible to ascertain if a car is well suspended by a simple inspection of the springs? This is a question that drivers often ask themselves. First of all, what is a well-suspended car?—a question that is much more difficult to answer than would be imagined. One often feels, in comparing the riding qualities of one car with those of another, the difference in the comfort; but there lies a set of variable quantities even in the same car, according to the road surface, the weight carried, the state of lubrication of the springs and also the question of shock absorbers, and so on.

Quite independent of the want of comfort of a badly suspended car, it is safe to say that it is far from economical. From two points of view such a car is a burden. First, on account of the continual bumping of the driving wheels on the ground and the harsh recoil on the road surface, each blow thus struck forms as it were a rasp of great power that causes the tire to part company with the precious rubber casing. This inconvenience is particularly noticeable on certain shaft-driven cars. Secondly, one thing must be borne in mind, viz.: every shock and every resulting vibration takes away power from the motor, which will entail an increased and unnecessary consumption of gasoline. It has been noticed in some cars, to which shock absorbers of good construction properly regulated have been added, that by simply removing one leaf of the spring an increase in fuel consumption has resulted, even as much as 1/3 to 1-2 of a gallon in 100 miles, according to the power of the motor, and without touching the carbureter regulation at all.

The question of good suspension is a vital one in the conservation of a car. The shocks and vibrations quickly cause the homogeneity of the different points that are attached to one another to become broken. There is not a car made in which there is not some vibration, and this must be eliminated as far as possible. Besides, it is a well-known principle in mechanics that a noisy machine cannot be economical. It remains, therefore, to consider the different methods that can be used in order to better the suspension of a given car.

At the outset there is a question of the why and the wherefore. Why is it that manufacturers do not make all cars with soft springs? There are two reasons for this—one being that they cannot know beforehand if the car is to be fitted with a light touring body or a limousine, and they choose, and rightly so, a happy medium by fitting semi-soft springs. In most cases when a chassis is tried out on the road on what is called the road test it is fitted with two spider seats and a box which should be fitted with weights, but these are seldom used on account of the tiresome operation entailed in the lifting. It is evident, therefore, that the chassis is tested for mechanical efficiency only, the question of suspension not being considered in the trial. The second reason is that constructors, relying on the excellence of certain shock absorbers which are to be found on the market, and which can be regulated according to the weight of the car, leave this regulation of the springs to their clients. It may be noted that several manufacturers of high-grade cars deliver their chassis already fitted with shock absorbers, and it only remains to adjust them. This is, perhaps, one of the happiest solutions of the suspension problem.

How can one find out *a priori* whether a suspension is soft or hard? It has been shown that the springs should be—

1, sufficiently flexible to absorb the shocks due to the inequalities of the road;

2, sufficiently resisting and elastic so as not to take permanent deformations under a heavy weight or from a very violent shock.

What is known as the flexibility of the spring is the quotient of the flexure divided by the weight of charge, and it is calculated in millimeters per hundred kilograms. There is another point to be considered, and that is that in cases of great oscillation the chassis shall not touch the axle.

The flexibility of a spring depends upon its dimensions; it is advantageous to use springs sufficiently long to withstand the large amount of deformation and sufficiently broad to give the car a trim so that it will withstand the transverse strains. In order to take care of this latter it is necessary to always place the rear springs, which carry the most weight, outside of the chassis frame and as far apart from one another as possible. The front springs, which only have to support the weight of the motor and to resist the oblique strains when the wheels strike obstacles, are always under the chassis, which allows of a larger lock for the steering wheels. The length of the spring ranges between 800 and 1400 millimeters (31 1-2 and 55 1-8 inches), measured between the axes of the spring bolts, and the thickness varies from 4 to 12 millimeters (.1517 to .4724 inches). As a general rule the longer the springs are and the wider and thicker the more flexible they will be. This is only relative to the different leaves that form the whole spring.

The entire spring has to resist flexure and torsion, and it is impossible to construct the spring of a single leaf for the double reason that the more leaves there are in the spring's construction the more flexible it becomes; and on the other hand it is more costly. The springs are generally of decreasing length, starting with the master leaf, which is directly connected to the chassis by means of shackles or scroll irons, as shown in Fig. 1. The leaves are held together by a center bolt attached to the perch of the axle by means of clips with a block interposed. As at flexure moments the give of each of the elementary springs is diminished (certain springs are quite flat when not acted upon and work in counter), it follows that the extremities of each of the leaves are displaced and each slides on the one next to it. They are guided in this relative movement by detention pins for the master leaf and by projections in the notches of the other leaves. One thing, therefore, stands out quite clear—the relative movement of the leaves must be facilitated by lubrication. It is most important that this point should receive the amount of attention it requires. Vaseline should be used and spread on the leaves with a piece of cloth while the spring is disassembled. The chassis can be lifted with a jack if it is not found convenient to take the springs apart; this has the effect of causing the leaves to gape in the manner shown in Fig. 2, and with a long-spout can oil may be introduced between the leaves; but the oil should be fairly thick. It has been suggested that springs should be protected from the dust, mud and especially the water used when washing the car, by means of pliable leather covers or some other waterproof material. It would be possible by that means to always maintain the suspension in the same condition and as supple as originally. On quite a number of cars one can see small rusty blotches, which show that the springs are never lubricated.

One means of keeping the leaves in perfect condition consists of introducing between each leaf a very thin layer of special bronze; by that means an automatic lubrication is obtained which is excellent from the point of view of suppleness.

The different leaves have radii of curvature which cross from the smallest to the master leaf; that is to say, the short leaves are more circular than the larger ones, so that the contact between the different components shall be equal over their entire length. Under these conditions it is easy to see that the friction existing between the leaves is opposed to the brutal expansion of the spring and the dual purpose is served as follows: The lubrication of the leaves renders their sliding movement easy under the compression, which permits the spring to absorb as completely as possible the sudden force of the shock during the expansion; the movement is, besides, lessened, which absorbs in a certain degree the oscillations.

The period of oscillation of a spring is quite appreciable; this period may be equal to the frequency with which the shocks are received, or it may be a multiple. In this latter case the amplitude of oscillation may grow indefinitely and cause the breakage of the spring. This may happen on very stony roads, and the only thing to do under such circumstances is to slow down.

Springs may be classified into several categories, as shown in Fig. 3:

1. Half elliptic, that can carry a shackle at either of the two extremities or at both; very much used.

2. Elliptic, consisting of top, half elliptic; bottom, half elliptic, united at both extremities by bolts; not used in present-day construction.

3. Three-quarter scroll elliptic, consisting of upper, quarter scroll; bottom, half elliptic. They are hinge springs when the top half is as shown in A-3 in Fig. 3 and shackle springs when it is curved and attached from underneath to the lower spring, as shown in B-3, Fig. 3. The first type is found fairly often, and the second is found frequently on good cars.

4. C springs, sometimes found on cars de luxe, are very curved —a construction that costs money without adding much to the suppleness.

5. The half springs that are found on some of the cheaper grades of cars have the inconvenience of imposing a large amount of work on the chassis supports.

These considerations, together with the length of the leaves, their number and the width and thickness thereof, permit one to obtain an idea of the suspension of a car for a predetermined weight.

It is a wise plan to mount the axes of the spring shackles with a cardan to prevent the torsion effect being transmitted to the spring. This is found in but one make of car, as far as it has been possible to discover, and that is the Daimler. There are a number of cars of modern manufacture that are not fitted with greasers on the spring bolts with the ordinary type of shackle; these rust up and bind, making a horrible noise and wearing out very quickly and occasioning sometimes a sudden rupture. This is one point of the suspension that should receive attention, and

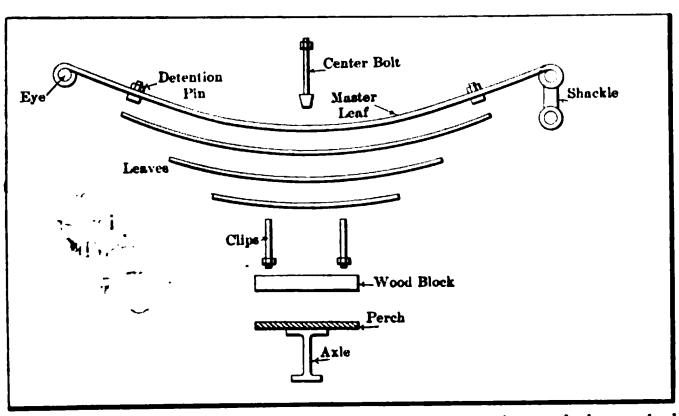

Fig. 1—Different component parts of a semi-elliptic spring and the method of attachment

in purchasing a modern car one should insist on such grease cups being fitted to the shackle bolts as well as the front spring bolt.

The suspension can be improved considerably by using the properties that reside in spiral springs, as these have a period of vibration much shorter than springs of the leaf type. The amount of tension of the spring can be adjusted when it is attached to the shackles in such a manner that it dampens very quickly the vibrations of the suspension. As a whole the good suspension of a car is realized by the use of long and broad springs, with a small amount of flexure and made of good steel, with a preference for that with a percentage of silicon or tungsten. The softest suspension will be found in cars with three-quarter elliptic springs in front (very seldom used) or half elliptic springs; and for the rear using a three-spring suspension known as three-point suspension or by half scroll elliptic springs.

Under normal running conditions the small vibrations that are not greater than 20 millimeters are absorbed by the tires, but for

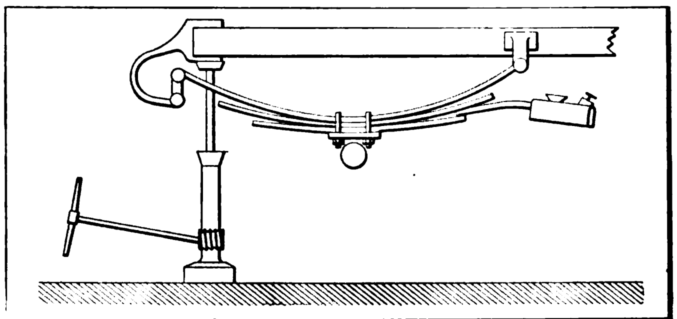

Fig. 2—Method of lifting the chassis by means of a jack so that the leaves will separate and allow oil to be inserted

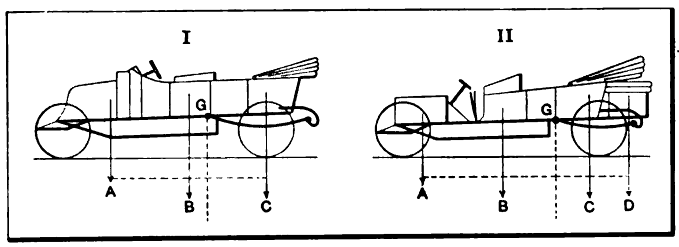

Fig. 4—Showing the difference between the centration of the masses on two different types of cars. It will be noticed that the masses A and D in II are far away from the general center of gravity G in comparison to car I

larger vibrations the spring deflects and by reaction the chassis is forced upwards. In consequence of the inertia of the total mass in movement the bending of the spring becomes greater than it would otherwise be in a state of equilibrium, the recoil and the series of oscillations being the cause of all the discomfort in the car. These oscillations are more dangerous than would be imagined, causing as they do a lifting of the driving wheels and consequently a diminution of adherence; the wheels slide and when contacting with the road surface the tires are subjected to a rasping action each time, causing rapid wear.

In shaft-driven cars the non-suspended mass comprised of the differential and casing together with the wheels and brake drums is very important because the weight may be as high as 180 kilogrammes (about 400 pounds), but in the case of chain-driven cars this weight is not more than from 120 to 150 kilogrammes (264 to 330 pounds). Here is one cause of the wear of tires on shaft-driven cars in excess of chain-driven cars, independent of the road-holding properties, which may be bad, according to the suspension. This may be improved by using springs that have been carefully studied and fitted with shock absorbers properly adjusted. Further, the shaft-drive is drawing recruits every year more and more owing to the silence, its more mechanical aspect, its cleanliness and efficiency.

The duty of shock absorbers (Fig. 5) is, by means of additional friction, to exterminate the oscillations of the springs that have taken effect under the conditions above stated. These can be classified into four heads, as follows:

1. Friction of two surfaces one against the other.

2. Breaking effect on a liquid under pressure passing through a small orifice.

3. Superposition of the oscillations to be absorbed by those which are much shorter in an antagonistic spring.

4. Air compressed in a cylinder.

There is one point in the suspension of cars that is of especial interest, and that is the centralization of the masses of the car. This question is often ignored by drivers, whereas it should have a great deal of interest for them. It is a well-known fact that a high vehicle, such as a limousine or any covered car, has a tendency to slip in going around corners because the center of gravity is higher than in an open body, which is much lower. But the influence of the distribution of the super weight on the car is also important. One often hears among drivers conversations in which it is stated that such and such a car has a greater tendency to skid on corners than another *because there is too much weight on the back axle.* This is an incorrect method of explaining matters. This inconvenience does not come so much from the amount of weight of charge on the axle but rather from the great amount of distance that is present between the charge and the center of gravity. In order to reduce as much as possible this bad effect on the suspension it is necessary that all the important weight of the car should be as near as possible to the center of gravity of the general system (Fig. 4); in other words, it is necessary that the radius of gyration of each of the important masses should be as small as possible. Under these conditions the inertia effects on these same bodies will be much less on the holding properties of the car on the road surface, as their lever arms will be very small. Under the ordinary running conditions they can be in a vertical longitudinal plane, which is the *galop* movement, alternately tending to surcharge one axle and alleviate the other, and it is dangerous for the tires and upsets the riding comfort of the car. In a vertical plane perpendicular to the axis of the car the rolling movement is less dangerous while driving in a straight line than when rounding corners. Finally in a horizontal plane there is a side rolling which is liable to cause a skid.

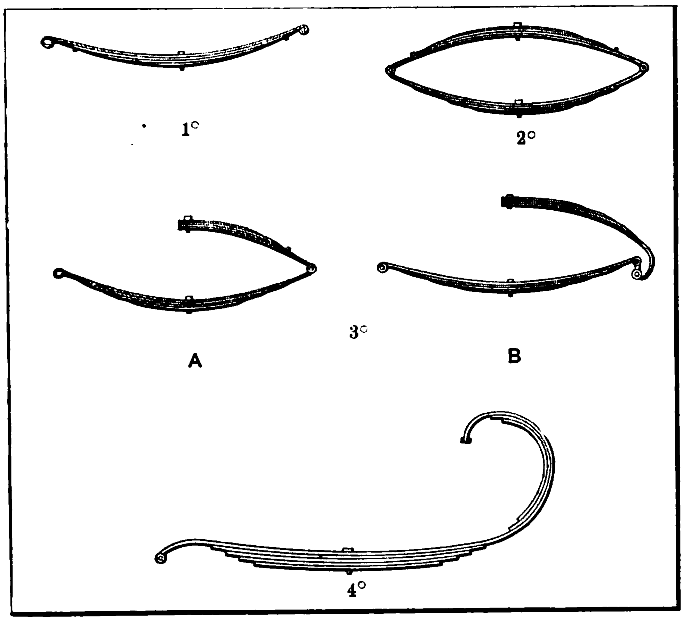

Fig. 3—Different types of springs used in automobile construction

It is possible to see from this short outline how the centration of the masses of a car has an effect on its holding properties on the road and also on the suspension.

The two following rules may be laid down: 1. The general center of gravity of the car should not be too high and about two-thirds of the distance between the axles taken from the front (three-quarters at the outside). 2. It is necessary that the center of gravity of all the important bodies on the car—that is to say, the passengers, their luggage, heavy spare parts and tools—should be as near as possible to the general center of gravity. It is possible at the present day to make a car with a soft suspension, or, at any rate, greatly better a harsh car.

British Army Taking Up Motor Transportation

By the conversion of the present horse-drawn system of transports into a series of completely equipped motor supply trains the heads of the War Department expect to simplify the organization of the transportation service of the Expeditionary Force. An epidemic of motor car inventions has struck England during the past six months.

THE British Army Service Corps is making a decided move in the direction of mechanical transportation, as the outcome of a number of years of experimental and development work. It is intended to convert the major part of the administrative transportation of the Expeditionary Force, both as relating to supplies and ammunition, into self-propelled transports. By the adoption of this method it is argued that a radical simplification in the organization of these services in the field will be wrought simultaneously. An epidemic of inventions relating to the motor car marked the first six months of the present year in England. These included solidified petrol; a type of coal-fuel engine; new kinds of valve gears, built "without seriously threatening the standard practice;" and a rotary steam engine. The inventor of this engine claims for it a really novel feature, which, he says, may be considered as endowing it with a chance to figure seriously in the evolution of the automobile. He declares that a signal virtue of the motor is the abolition of change-speed gears; the second advantage is found in a reduction of friction; and the third in the increase of steam tightness, the rotor bearing against two roller bearers, which in turn are freed from friction to some extent by being held up to their work by a steam cushion. That is to say, each roller bearer is made a floating fit in its own tunnel, while steam is admitted to a recess on the side of the roller, away from the rotor. Except for these features and the fact that it is constructed to run as a turbine when greater power is wanted, the engine in question does not appear to differ radically from the type of some other engines that made their appearance years ago.

"Doing" the Chateau Section in Automobiles.—One concern in France is carrying passengers through the Château section of the country by automobile, the journey occupying six days, going and returning. The fare is 500 francs. Starting from Paris, the first day's run is to Chartres, the second is to Tours, the third embraces the vicinity of Tours, the fourth day leads the tourists to Blois, the fifth is passed in and around Orleans and on the sixth day the motor car fetches its passengers back and puts them down in Paris.

Discussing Brick for Pavement

Detailing the Vogue of the Best Results

Will P. Blair, Secretary of the National Paving Brick Manufacturers' Association, illustrates and discusses the ramifications of brick pavement, presenting the ideas which should be uppermost at the time of laying pavement of this type, and offering suggestions that should be of interest to the automobilist, enabling him to intelligently advocate the building of good roads.

IN order to better understand the suggestions here offered a cross section is given by way of illustration. (See Figs. 1 and 2.) It will be noticed that the improved portion, including the ditch, occupies a width of 47 feet, so that at least 50 feet right of way is required for a like road. This is a type that has become very popular in northeastern Ohio. We give first attention to the manner and method of construction and the reason therefor, under the belief that the why should be known to the automobilist with as much reason as he should know why any part of his machine is made in this or that way. It is the advantage that appeals for favor, so right methods should persuade their use.

To assist drainage and avoid danger of heaving by frost, the concrete curb is made in form so that the base shall rest upon a sub-base of gravel, broken stone or cinders.

For draining the road bed in most soils, a small tile, laid parallel with the curb with T outlets at intervals of every 10 feet will answer; if, however, the soil is of such character that the water by capillary attraction fills to the uttermost, then to avoid frost action incident to our more northern climate, it is necessary to tile the road bed alternately as illustrated in Fig. 3.

Drainage is thereby assured quickly, avoiding the possibility of the ice obstructing the water, as often happens with lengthy drains, stopping the flow of water altogether.

The top of the curb shall be flush with the top of the pavement, so that the water will run off the pavement with even distribution at the lower edge, and therefore not liable to destroy the berme. After excavating to the required depth, care should be taken to compress the sub-foundation, rolling with a roller not exceeding 5 tons in weight. The surface should be made to conform to that of the finished street. The base should now be put in of concrete, using Portland cement 1 part to 8 of gravel or broken stone and sand. The gravel and broken stone should have enough of the smaller sizes which, with the sand, will fill the voids and assure such a mixture after the water is applied as can readily be brought to a smooth surface conforming to the grade of the finished street.

Unless made smooth, the next step, that of preparing the sand bed and providing for a space along the curb for the expansion cushion, is scarcely possible. The sand should be spread by the aid of a template, and compressed to a uniform cushion by a hand roller weighing 300 to 350 pounds. This cushion should be uniformly two inches in thickness and thoroughly compressed. The support of the wearing surface will then be uniform under each brick, giving sufficient relief from the vibrations caused by the impact of travel, so that the cement filler subsequently applied will not shatter, and yet be a support that will greatly resist the weight of any load and prevent the filler bond from breaking and the brick from chipping. The expansion cushion should be put in last of all, but provision should follow the completion of the sand bed by placing a board along the curb, at least an inch in thickness for 14-foot roadway, and thicker for a wider road. This board should be made into two strips as shown in Fig. 4, held away from the curb by a piece of hoop iron hung over the boards, the longer end dropping behind the boards, so that when the time comes to remove the boards it may be readily accomplished by first taking out the hoop iron.

This board should remain in place until the road in all other respects is finished. The brick should be distributed along the line of work and piled outside the track which is being paved, taking the greatest care to protect them against mud and dirt. They should be laid on the bed thus prepared at right angles with the street, with the best edge uppermost, and as nearly as possible so the jointing line will cover the center line of each alternate row. Bats should then fill the end openings. The important matter in this work is that the brick shall be placed best, or face, edge up in the first instance, not only making a smooth surface, but avoiding a second operation in the work which disturbs the uniformity of the sand cushion. The surface should then be swept clean of spalls and dust and rolled with a steam roller, weighing not more than 5 tons, rolled until the unevenness in the surface is rolled out, rolling both by moving the roller at right angles and at 45 degrees.

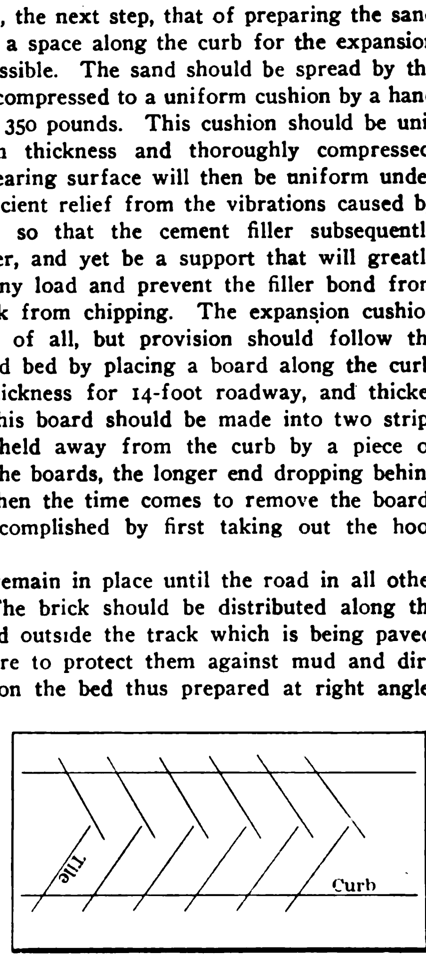

Fig. 3—Showing the diagonal courses of the pavement

The next operation, that of applying the filler, is too often regarded as of minor importance, and details necessary to insure a perfect and durable pavement are ignored altogether, and while inexpensive and easy to comply with, a disposition to carry out in full the details is necessary or it will not be done.

The filler should be composed of one part each of clean, sharp sand and Portland cement. The sand should be dry. The mixture, not exceeding one-third of a bushel of the sand, together with a like amount of ce-

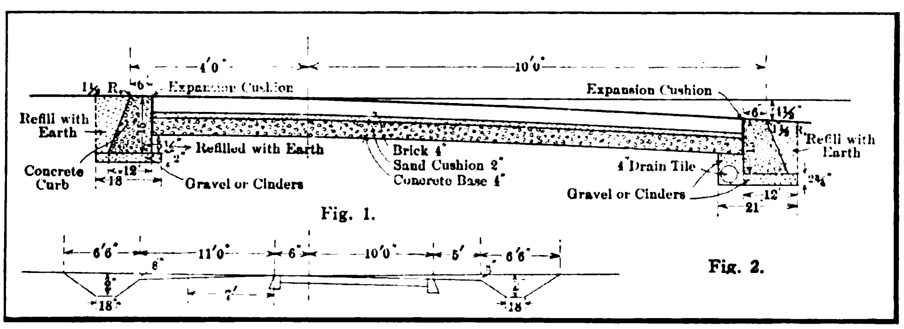

Fig. 1—Section of a brick-paved street showing the details of construction. Fig. 2—Dimensional information related to Fig. 1

ment, shall be placed in the box and mixed dry, until the mass assumes an even and unbroken shade. Then water shall be added, forming a liquid mixture of the consistency of thin cream.

The side and edges of the brick should be thoroughly wet before the filler is applied by being gently sprinkled.

From the time the water is applied until the last drop is removed and floated into the joints of the brick pavement the mixture must be kept in constant motion.

The mixture shall be removed from the box to the street surface with a scoop shovel, all the while being stirred in the box as the same is being thus emptied. The box for this purpose shall be 4 feet 8 inches long, 30 inches wide and 14 inches deep, resting on legs of different lengths, so that the mixture will readily flow to the lower corner of the box, the bottom of which should be 6 inches above the pavement. This mixture, from the moment it touches the brick, shall be thoroughly swept into the joints.

Two such boxes shall be provided in case the street is 20 feet or less in width; exceeding 20 feet in width, three boxes should be used.

The work of filling should thus be carried forward in line until an advance of 15 to 20 yards has been made, when the same force and appliance shall be turned back and cover the same space in like manner, except to make the proportions two-thirds cement and one-third sand.

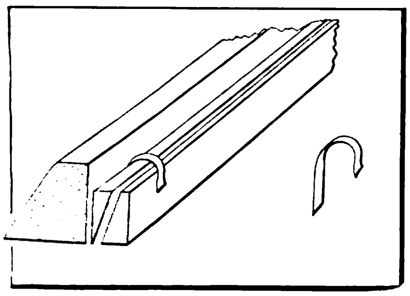

Fig. 4—Section through a curb, showing the expansion member

To avoid the possibility of thickening at any point there should be a man with a sprinkling can, the head perforated with small holes, sprinkling the surface ahead of the sweepers.

Within one-half to three - quarters of an hour after this last coat is applied and the grout between the joints has fully subsided and the initial set is taking place the whole surface must be slightly sprinkled and all surplus mixture left on the tops of the brick swept into the joints, bringing them up flush and full.

After the joints are thus filled flush with the top of the brick and sufficient time for hardening has elapsed, so that the coating of sand will not absorb any moisture from the cement mixture. one-half inch of sand shall be spread over the whole surface, and in case the work is subjected to a hot summer sun, an occasional sprinkling, sufficient to dampen the sand, should be followed for two or three days. Grouting thus finished must remain absolutely free from disturbance or traffic of any kind for a period of ten days at least.

After this comes the last operation in finishing the street, that of removing the expansion board along the curb and filling the space so as to allow for the expansion. For this purpose a pitch or asphaltum mixture that will retain the greatest elasticity during low temperature should be used. This will often prevent expansion cracks even by low temperature and unquestionably prevent them during seasons of high temperature. An illustration of this kind of road is here actually given in Fig. 5 from a photograph of the same.

With many roads even put to excessive use a less width for the paved portion will be found entirely sufficient. It will be noticed that in the type here given it is provided for a seven-foot graded track alongside of the paved portion. If a road of less width is chosen the graded earth portion should be at least seven or eight feet in width and the paved portion not less than nine

---

More than 1,000 chauffeurs' licenses have been issued in the Province of Ontario. The driver's average wage is $60 monthly. It is an exceptional case in which a driver receives $20 per week.

As to the Silent Chain

Apart from its quiet operation, the principal advantage of the silent chain lies in its flexibility, one of the most desired properties to be found in a mechanism. Liberal size and the best of quality as regards material will insure its success in operation.

NOW that silent chains are coming into use quite extensively, discussion is being entertained bearing upon the reasons why these silent chains afford an extra measure of advantage, and it is more than likely that the discussion will lead to a point that has been too frequently overlooked in the past. Flexibility is one of the most desired properties that can be found in a mechanism, and the advantage to be derived from its presence can no more fittingly be illustrated than to call attention to a fact that a locomotive may pull as many as 100 freight cars, gaining speed from a standstill, under the conditions under which freight cars are built, taking advantage of a spring coupling, thus making it possible for the locomotive to start one freight car at a time, which is all that it does. Were the freight cars in rigid relation with each other it would be utterly impossible for a locomotive to start even a small part of the cars that compose a train under ordinary conditions. The secret lies in the flexibility that is induced by the spring bumper, and, come to think of it, the amount of play that is permitted by the bumpers is very slight indeed. The silent chain as it is being employed in automobile work has all the properties of the spring bumper that serves so efficaciously in freight train work, and it is fitting that advantage should be taken of this condition in favor of flexibility, since it is being found in practice that there are almost no disadvantages at all. The chances for mistakes are in the direction of using chains that are too small for the work to be done. A well-made silent chain is a relatively expensive device, and the influence would naturally be in favor of some method that would have a favorable influence upon the cost of the application of these chains. There are only two ways of reducing the cost of applying silent chains, one of which has for its basis the use of an inferior product, and the second idea is coupled up to the use of a well-made chain of a reduced size, considering the work to be done. It is not possible for a designer of acumen to take advantage of these ways of reducing cost, and the ultimate success of the whole project lies in the use of liberal-sized chains, leaving the quality above suspicion.

What Some Subscribers Want to Kno

Strong Desire to Get Out of Tire Troubles

Editor THE AUTOMOBILE:

[2,747]—I would appreciate an answer to these questions: (1) How can I remedy the following: I have a quick detachable straight-side tire, the bead of which has been stretched by allowing it to run flat. I have continuous trouble with these tires on account of their pinching or blowing out under the bead. I have tried wrapping tape around the rim, which, although it helps some, is not an absolute success.

(2) I have a Mitchell Model L 1909 car which has given me trouble by the rapid wear of the cones and ball bearings. When I take a wheel off to examine it I find the cones badly worn on the under side. After replacing with new cones and ball bearings I soon find them in the same condition, making, while running, a noise similar to the sound of the speedometer gears on the average car, although I pack the bearings with grease every month or so and see that they are properly adjusted. If you can give me any advice as to how to remedy this trouble it will certainly be appreciated.

(3) When the differential on this same rear axle is packed with grease why should it leak out around the brake bands or drums? A. V. M.

White Hall, Ill.

(1) The trouble in the tire is no doubt due to insufficient inflation or, perhaps, to a leak which takes place after a certain pressure has been attained. The pinch will take place at the top of the wheel if the car is standing or running with the tire flat. The accompanying illustrations (Figs. 1 and 4) will show the position taken by the tire at the top and bottom of the wheel when not pumped to the required pressure. The remedy is obviously to maintain the tire pressure required by the weight of the car.

(2) If the bearing is not adjusted too tightly, a trip to the repairman would probably be of benefit, as there may be something out of alignment. A little play should be allowed in the bearing so that after spinning the wheel it will finally come to rest with the tire valve at the bottom.

(3) This tendency of leakage of the oil from the differentials into the brake drums is a common occurrence with a large number of cars. On the latest models the makers are using some device such as a baffle ring to prevent it.

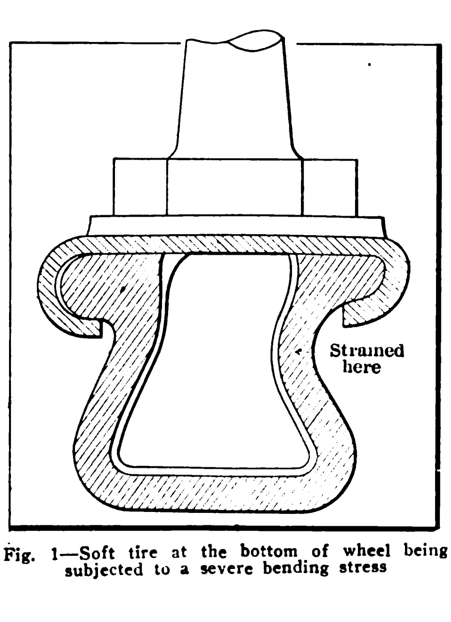

Fig. 1—Soft tire at the bottom of wheel being subjected to a severe bending stress

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their automobile troubles, stating them briefly, on one side of the paper only, giving as clear a diagnosis as possible in each case, and a sketch, even though it may be rough, for the purpose of aiding the Editor to understand the nature of the difficulty. Each letter will be answered in these columns in the order of its receipt. The name and address of the subscriber must be given, as evidence of good faith.

Another View of the Situation

Editor THE AUTOMOBILE:

[2,748]—In your issue of June 22nd, under the heading of "Short Stories of Common Interest," I note your article on "Lubrication," in which the lubricating oil is mixed directly with the gasolene. I have very carefully watched, during the last several months, these articles, especially as they have been explained by Charles E. Duryea, and your answers thereto. Now, I cannot see how anybody could have misconstrued the meaning of this method of lubrication, for I am sure that Mr. Duryea frequently mentioned that its adaptation was only suited for two-cycle work. He did, however, in several articles, state that by adding a very small quantity of lubricating oil to the gasolene the running qualities of any four-cycle motor would be greatly improved. This I know to be true, as I have tried this method and am using it at the present time. I am sure he did not recommend this system for four-cycle work, to be relied upon as the sole method of lubrication. It was his contention that it would improve the running of the engine and meant that the regular method of lubricating should be employed as each maker originally provided.

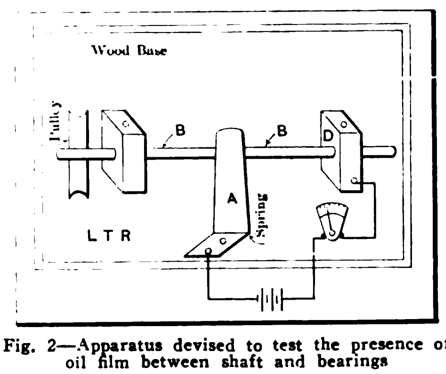

Fig. 2—Apparatus devised to test the presence of oil film between shaft and bearings

Now in regard to the two-cycle lubrication in this manner, I must advise that my business relations have been such that I have had the honor of calling upon the majority of the two-cycle engine manufacturers and I find that where any of them have ever tried this method they are still using it and their enthusiasm in recommending this style of lubrication is great.

Recently a friend of mine brought up the question of this style of lubrication and also of Mr. Duryea's talks, and he assured me that he used this system on several thousand engines, and that he found it to be without any question the most superior method he ever tried, and his experience covers at least nine years. He also advised me at the time that he would appreciate having his method of oiling brought to your notice. Disregarding all theoretical and technical arguments to the contrary, this sort of evidence would be most convincing to most of us and, to use Mr. Duryea's own language, I would say that "Facts are stubborn things."

Further in your article you say, "Authoritative statements emanating from high sources relating to the lubricating problem all go to show that it is the duty of lubricating oil to furnish an unbroken film between the journal and the box." Regarding this statement, I beg to advise that while I do not claim to be of this high source of authority, I do claim that this is absolutely wrong, as the following simple experiment will show:

Most of us know that lubricating oil is a non-conductor of electricity, at least of currents of 25 volts or less; therefore, if a film of oil is maintained between a journal and a shaft no current would flow through the circuit shown in the accompanying Fig. 2, which sonsists simply of mounting two pieces of brass with holes drilled in shaft B to bearing D, then from the voltmeter to the opposite side of the battery. If the oil maintained the above-mentioned film it would certainly insulate the shaft from the bearing and no current would flow or at least the voltmeter would fluctuate, showing a broken or interrupted contact.

You may, no doubt, be surprised to learn that the meter shows a perfectly steady current passing through this journal, clearly disproving the fact that the shaft is not in absolute metallic contact. In this experiment we have a pressure on the shaft of a spring of possibly five or six ounces. Certain it is that if the film of oil is broken by this light pressure, in an explosive engine where the pressure on the

What Other Subscribers Have to Say

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their personal experiences for publication in these columns for the worthy purpose of aiding brother automobilists who may be in need of just the information that this process will afford. Communications should be brief, on one side of the paper only, and clearly put, including a rough sketch when it is possible to do so, and the name and address of the writer should be given as evidence of good faith.

crankshaft becomes a number of hundred pounds, this argument of the oil film does not hold good.

The theory of the oil film has been handed down from one textbook to another and it seems that it has become a universally accepted term, just as some other theories have been allowed to pass from one generation to another. I have constructed the apparatus shown in the illustration for the sole purpose of verifying the authenticity of the argument.

I would not have answered the above article if it were not for the fact that I believe that Mr. Duryea's contentions are perfectly correct and that I happen to be in possession of this information, which is certainly authentic.

I earnestly trust that you will see fit to publish this in your valued journal, which is, to say the very least, an educational medium of the highest order.

LEWIS T. RHOADES.

New York, N. Y.

Coat the Driving Faces of the Coupling with Solder

Editor THE AUTOMOBILE:

[2,749]—I have been troubled a great deal by the rattling of the Oldham magneto coupling. I have tried everything I can think of to remedy this, but it still continues. Can you suggest some other form of coupling that I might make myself which would overcome this objectionable feature?

ROBERT DENTON.

Wellesley Farms, Mass.

A Knock in the Cylinder

Editor THE AUTOMOBILE:

[2,750]—Can you inform me what will stop a knock in the cylinders of my car? The knock seems to be a side lash from the pistons. Would you suggest reboring the cylinders, as the pistons seem to be in perfect order? WM. FISCHER.

Evansville, Ind.

If the piston itself is in proper order the knock is probably due to worn piston rings, which should be replaced. Another cause of knocking in the cylinders and one which is at times very hard to detect, is a loose wrist pin. If the cause of your trouble is neither of these two the remedy will lie as you suggest, in reboring the cylinders.

Wants Information on Timing

Editor THE AUTOMOBILE:

[2,751]—Could you give me any information on camshaft and magneto timing? I have taken the camshaft and magneto off my motor and wish you would give me the correct setting so that I can get these back into their respective positions. It is a four-cylinder motor with a Bosch magneto. A SUBSCRIBER.

Toronto, Canada.

The accompanying cut (Fig. 3) gives in graphic form the desired information. A very good practice is to put a center punch mark on the engine frame near the flywheel. Corresponding marks are put on the flywheel at each valve opening or closing and marked with the initials of the operation which takes place when the marks on the flywheel register with the mark on the casing. In this manner whenever the engine is taken down it may be assembled again without difficulty.

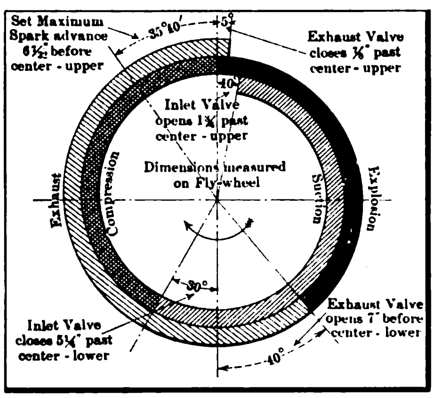

Fig. 3—Diagram for use in timing motors, giving the timing of a motor on a basis of flexibility of performance

Trouble with the Coil

Editor THE AUTOMOBILE:

[2,752]—For some time I have been having trouble with the ignition on my car. After having searched for a long time I have finally located the cause of the trouble and find it to be in the coil, as every other part of the ignition system is perfect. Could you give me any advice as to how to make any adjustments which may be necessary? M. F. BRONSVELD.

Centreport, N. Y.

Your trouble is probably due to either a badly adjusted vibrator or the contact screw of the vibrator may be loose. If the former, it may be adjusted as follows: Turn the engine over slowly by hand until the contact is closed; then turn on the switch and see if the vibrator will buzz. It should vibrate so rapidly that the sound produced is a sort of humming or singing sound. If this is done and the motor runs all right on low speeds and misses on high, the adjusting screw is too tight and the trembler has not time to vibrate well in this condition. The screw should be loosened.

Has Compression Troubles

Editor THE AUTOMOBILE:

[2,753]—I have discovered leaks in the compression of at least one of the cylinders of my four-cylinder motor. I do not know what the cause of the leakage is or just where it occurs and would greatly appreciate any information you may give me as to how to proceed to remedy this. As I have plenty of time and a little mechanical ability, I would like to do it myself.

W. BOOTH.

Cairo, N. Y.

A good method to follow in testing for the location of compression leaks is to fill an oil can with water in which a small piece of soap has been dissolved, and pour this around every spot that a leak could possibly occur. An assistant should then turn the crank of the motor very slowly and all the spots into which the water has been poured watched for bubbles which will indicate a leak.

If no leaks are discovered in this way the valves should be ground with emery dust and oil, being finished with tripoli and water. If the leak has not been remedied after these processes the piston rings should be examined

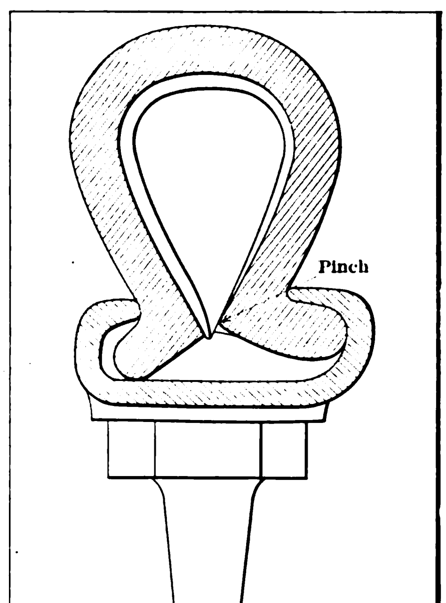

Fig. 4—Position of soft tire at top of wheel, showing how the inner tube is pinched

Meeting Recurring Troubles

Presenting a Series of the Most Probable Cases

A series of correlated short stories, accompanied by diagrams and characteristic illustrations, including the nature of the troubles that are most likely to happen to automobiles, discussing their causes and effects, all for the purpose of arriving at a remedy. It is the aim for the most part, to show how these troubles may be permanently remedied, and as a secondary enterprise it is indicated how the automobilist can make a temporary repair, thereby enabling him to defer the making of a permanent repair until a convenient time arrives.

Lubrication of the Knox Cars—The Knox cars are lubricated by the De Dion force-feed system. The oil is kept in constant circulation by means of a pump. This pump is of the gear type and is operated by means of a vertical shaft, driven directly off the cam shaft and operating not only the oil pump but also the spark timer.

The oil reservoir is in the lower half of the crankcase and forms an integral part of the engine casing. The oil level in the reservoir is never allowed to come so high as to permit the connecting rods to dip into the oil, as this would cause too much oil to be thrown into the cylinders.

The gear pump draws the oil from the bottom of the crankcase and forces it through a main feed pipe over to the opposite side of the motor. The main feed pipe runs into a longitudinal pipe, meeting it at the center of the engine, thus distributing the oil in two directions along the pipe. From this pipe the oil is led directly into the main bearings by means of leads tapped into it.

The crank cheeks and crankpins are drilled to form an oil channel, and the oil enters this passage through an opening in the crankshaft at the main bearing. It then finds its way, being driven by centrifugal force, up into the crankpin, which has an opening leading into the connecting rod bearing. The connecting rod is also drilled, forming an oil passage up to the wrist pin. Oil is admitted to the connecting rod oil passage once in every revolution, when the opening in the connecting rod registers with that in the crankpin.

The cylinders are lubricated by the oil spray which is thrown off the cranks. The surplus oil from all the bearings finds its way back to the oil reservoir, from where it is again drawn through the system after having passed through a strainer.

There is a spring connection device on the pumpshaft, which, in case the pump should in any way become clogged, will snap by, thus preventing breakage of the more delicate parts.

A pressure gauge is located on the sloping floor board. The pressure may be varied at will by means of an adjustable by-pass located on the left-hand side of the motor. The by-pass must always be partly open in order for the system to work properly and should in general be set so that the gauge registers about four pounds pressure in the pump. For extreme speeds it may be allowed to run up as high as eight pounds.

The oil is supplied to the tank on the left-hand side of the motor, on which side there is also a means of removing the strainer from the reservoir and a pet cock showing the oil level.

The National Uses a Circulating System—The oil in the National lubricating system is kept in continual circulation. The oil reservoir is located in the crankcase which is divided in such a way as to have an inner and an outer bottom. The outer or lower bottom carries the oil supply while the inner bottom is in reality a sort of tray inserted in the casting and moulded in so as to provide an oil trough below each cylinder.

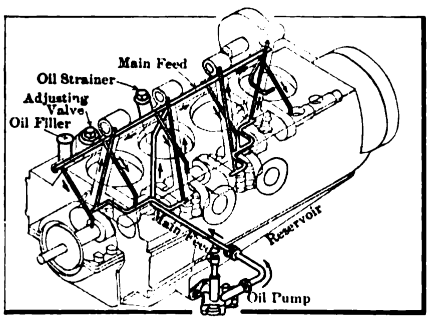

Fig. 1—The oiling system of the Knox cars, showing the course of the oil through the various leads by means of arrows

The connecting rods are equipped with scoop spoons which dip into the pools of oil which lie in each of these splash troughs. This dipping action throws the oil in the form of a spray into all the recesses of the crankcase and thoroughly lubricates all the moving parts located in the base of the motor.

To keep the oil in circulation there is a pump located within the crankcase which takes the oil from the reservoir in the base and forces it up through a sight-feed. After dropping through the sight-feed the oil returns by a vertical lead into the main oil pipe which runs the entire length of the crankcase and terminates in the lower part of the timing gear housing, which receives the oil in a small cup-like recess provided for the purpose. Some of the oil will be picked up by the timing gears and thus lubricate them, while the rest will overflow into the crankcase rapidly enough to keep the splash troughs full and overflowing. Above each of the crankshaft bearings

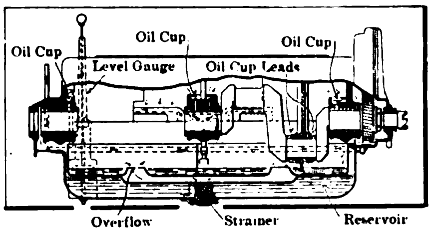

Fig. 2—Crankcase of the National, showing course of oil through the splash troughs and overflow pipes into the reservoir

there is also a cup which catches the oil from the splash and feeds it to the bearings through leads in the bottom of these cups.

All the oil draining off the bearings will join the overflow through the two standpipes provided, and return to the reservoir in the base. The course taken by the oil on its passage from the standpipes to the base leads through two pipes which join in the center of the base and then through an opening at the point of juncture of these pipes into a strainer of cylindrical form.

There is a level gauge on the side of the crankcase which shows at any time the amount of oil contained in the reservoir. This gauge is of the floating type with a ball located off the top of a vertical shaft projecting from the float. Drain plugs are provided in the bottom of the crankcase

Correja "35 A" Oiling Scheme—A combination of both the force-feed and splash systems is used on the Correja model "A" cars. The force-feed system is actuated by a pump which forces the oil to all the crankshaft, connecting rod and camshaft bearings. The pump is gear driven, being operated off the camshaft, and is located on the outside of the crankcase casting on the rear left hand side of the motor on the bottom.

The oil reservoir is in the bottom of the motor and carries the whole supply of oil. The pump lifts the oil from the bottom of this reservoir and carries it through leads to the various bearings mentioned above. After lubricating these bearings the oil will drain down into the splash troughs in the bottom of the crankcase. These splash troughs rest on a sort of tray above the oil reservoir.

The bearings supplied by the force-feed system will be given a greater supply of oil than can possibly be used by them, hence there will be a continuous overflow into the splash troughs which then become over supplied in turn, causing an overflow into the reservoir through the overflow holes provided for this purpose.

The connecting rods, even when running at a slow rate of speed, will descend into the troughs with sufficient momentum to dash the oil into a flying capor which completely fills the crankcase. This oily vapor will lubricate all the bearings not taken care of by the force-feed system.

The oil reservoir is filled through the breather tube. When the cover of the breather tube is removed the oil is poured down through the strainer

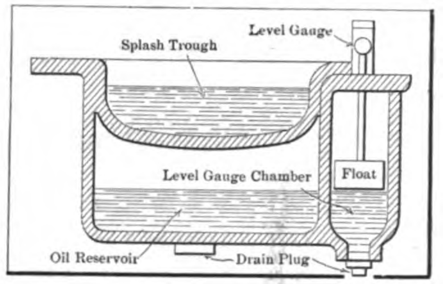

Fig. 3—Section through the Correja crankcase, showing the splash troughs and float level gauge

placed in the filler opening. There is a float level gauge on the side of the crankcase by means of which the amount of oil in the reservoir at any time may be determined by the operator.

The level gauge rests in a projection which is part of the crankcase casting. Beneath the projection carrying the float gauge there is a large drain plug. The oil level in the tank should never be allowed to sink so low that the little ball in the level glass is out of sight. It should be kept at about two inches from the bottom. As is necessary in a system of this kind, where the same oil is passed through the motor over and over again, a thorough system of straining is installed, the strainers being located in two places, viz., where the oil is supplied to the reservoir and again where it enters the pump.

In the Lubrication of the Bergdoll "30"—The Bergdoll 30-horsepower 4-cylinder motor is lubricated by the splash system. The crankcase is divided into four splash troughs into which the connecting rods dip. Besides being divided laterally to form the splash chamber the crankcase is also divided horizontally in such a way that the casting has a double bottom. The upper bottom is moulded in such a way as to form the splash troughs just described. Below the troughs in what may be called the lower bottom of the crankcase the oil is carried in a plain basin-shaped reservoir.

The reservoir in the bottom of the aluminum crankcase casting is filled through the breather pipe. In filling, the cover of the breather is removed, disclosing the filler opening equipped with a strainer. The upper test-cock on the side of the crankcase is left open while filling and oil is poured into the filler hole until it starts to flow from the cock. The cock is then closed tightly. The lower test cock is for the purpose of draining the reservoir, the oil never being allowed to become so low that there will not be a flow from this cock. The breather pipe is located on the exhaust side of the motor, just behind the magneto shaft. The oil is drawn from the reservoir by a pump which takes the oil from a suction pipe leading to the pump from the rear end of the exhaust side of the motor. The oil is then forced up through a vertical lead into the sight-feed located on the dash. Thence the oil flows down onto the opposite side of the motor and is lead into the crankcase at the forward end. The oil from this lead will fill the front splash trough and then overflow into the second and from there to the third and so on to the rear. After reaching the correct level in the rear splash trough, the oil overflows back into the reservoir through an overflow in the rear of the crankcase.

Since the oil supplied by the pump is in excess of the quantity necessary to form the splash it will be continually overflowing back into the oil reservoir, thus keeping up a constant circulation. So that a pure supply of oil will be insured to the pump a strainer is inserted in the system just before the pump through which all the oil must pass. The pump itself is located on the rear end of the exhaust side of the motor and is driven off the camshaft by means of gears.

The connecting rods dip into the oil while revolving and throw the oil in the form of a mist or vapor up into the engine, lubricating the entire motor, including cylinder walls, connecting rods, camshaft and main bearings. All these bearings will be oiled by the mist and in fact will receive an excess which will drain back eventually to the crankcase reservoir and be carried again through the system.

Vacuum Oiling System of the E. M. F.—The E. M. F. "30" car is lubricated by an en-

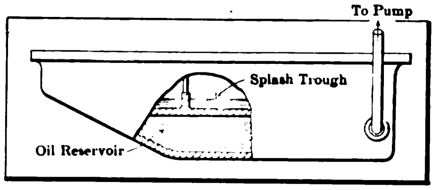

Fig. 4—Illustrating the oil pan casting of the Bergdoll with the lead to the oil pump

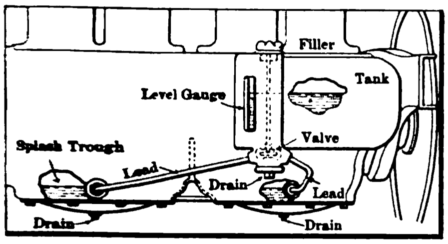

Fig. 5—E-M-F vacuum feed lubricating system, showing tank, level glass and leads to splash troughs

tirely self-enclosed and automatic vacuum-feed splash system.

The oil tank is an integral part of the crankcase and is located on the left hand side of this casting. The capacity of the reservoir is about one gallon. The tank is filled through an opening in the forward end which is covered by a screw cap so made as to screw down tightly so as to form an air-tight fit over the oil reservoir. This tightness is an absolute necessity to the system as will be seen later.

The oil is fed into the crankcase splash troughs by vacuum. Two feed pipes extend from the bottom of the tank into the crankcase. These pipes are U-shaped, one end leading into the bottom of the tank, while the other projects through the bottom of the crankcase, to a point about five-eighths of an inch above the bottom. When there is no oil in the crankcase, but the reservoir is full, it can readily be seen that there will be a flow from the reservoir into the crankcase by means of these two pipes. When there is sufficient oil in the crankcase to cover the pipe ends, they will be sealed so that no air can enter them and hence no more oil may flow out of the reservoir.

This system automatically supplies the oil that is used just as rapidly as it is needed and keeps the oil level constant, since the pipes are continued into the crankcase for just such a distance as to provide the correct level for the splash of the connecting rods. The oil cannot rush into the crankcase and flood it when filling the tank as there is a valve which closes automatically when the screw cap is removed. There is an opening directly under the valve in the bottom of the oiler, through which the valve may be taken out for inspection in case of leakage. Any leakage would be detected while filling the reservoir.

The splash of the connecting rods throws a spray up into the cylinder and fills the crankcase with oil vapor. This oil vapor lubricates the entire motor, including the camshaft.

The camshaft gears are lubricated through an oil hole and by means of grease cups which are provided for this purpose.

In order not to waste oil certain precautions must be observed in the monthly cleaning to which the crankcase should be submitted. The filler hole cap on the oiler box must be removed so that the oil does not pour into the crankcase. The drain in the bottom of the crankcase is then opened until all the oil has poured out, when the drain cock is closed. Kerosene should then be poured into the breather pipes and the motor allowed to run for about fifteen seconds. The drain cock is then opened and the kerosene allowed to run out. After the drain cock is closed and the filler hole cover screwed firmly back into place the oil will run into the crankcase until it reaches its proper level.

Self-Contained System of the S. G. V. 20-30 Car—The lubricating system on the S. G. V. 20-30 is absolutely self enclosed. The machine is lubricated entirely by the force-feed system, although by adding a gallon more oil to the supply an auxiliary splash could be obtained. For all the requirements of the ordinary automobilist, however, the system is fully adequate as it stands.

The oil is carried in the base of the motor in a reservoir which forms an integral part of the crankcase casting. This reservoir is filled through an opening which is located just above the rear left hand crankcase supporting arm. To fill the crankcase the screw cap which covers the filler opening is removed and the oil poured into the strainer which is located inside the filler opening to remove the foreign matter which is some times found to be in the oil supplied by the dealers, in spite of all the precautions taken to prevent such an occurence.

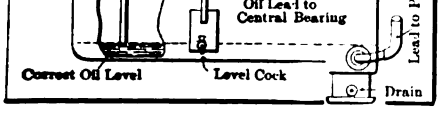

Fig. 6—The crankcase of the S. G. V. car, illustrating the oil well in the rear end to provide suction for the pump

In filling the reservoir, the cock on the side of the crankcase is left open. This cock is just at the correct oil level so that there will be no splash of the connecting rods into the oil as this would cause the motor to smoke since a sufficent quantity of oil is supplied to the motor by the force-feed system. In case of a splash there would be too much oil supplied and there would be danger of fouling the motor.

The oil is drawn from the crankcase reservoir by means of a suction pipe, and taken up to the gear pump which is located on the rear end of the camshaft. The pump then sends the oil under pressure to the main bearings where it enters the crankshaft after having lubricated the bearing. The pressure that is given by the pump is sufficient to overcome the centrifugal force at the main bearings and send the oil well along on its way to the cranks. The cranks are also drilled to provide an oil channel and the oil will be thrown through them by the force due to the rotary motion of the shaft. There is an opening in the crankpin through which the oil flows and lubricates the connecting rod bearing at this point.

The centrifugal force at the crankpins will force the oil up the leads in the connecting rod to the wristpin whenever the opening in the crankpin registers with the opening in the wristpin lead. At other times the oil will be thrown off the connecting rod bearings in a spray, thus lubricating cylinder walls.

There is a pressure gauge on the dash which shows the pressure on the pump.

The amount of oil supplied to the various bearings depends on the speed of the motor; an adjustment may be made, however, to regulate the amount of oil which will flow for any speed by means of an adjustable plunger on a by-pass through which the oil flows from the crankcase on the side of the motor. By increasing the

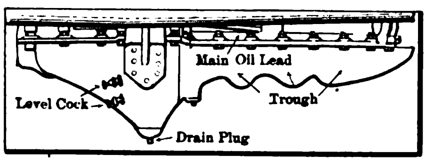

Fig. 7—View of the lower part of the Ford crankcase casting, showing the exterior of the splash troughs and the flywheel casing

tension on the spring which holds the plunger, the plunger can not be pushed back so far by the oil pressure, hence there will not be so large an opening for the oil to pass through, and the quantity will be diminished. In order to increase the supply at any speed the method of procedure is, of course, directly opposite.

The other bearings throughout the car are attended to in the usual manner by means of compression oil cups and oil holes. The transmission and differentials run in oil.

If the car has not been used for some time and the pressure gauge registers no oil pressure when the car is started, the priming cock on the top of the pump should be opened and a little oil poured in.

Lubrication of the Ford Cars—The Ford cars are lubricated by the splash system, the oil being kept at constant level by means of a circulating scheme keeping the oil constantly in motion.

The oil is carried in the bottom of the crankcase and also in the lower part of the flywheel casing, which is made oil tight by extending the cover plates of the crankcase so as to include the flywheel.

The flywheel proper consists of a number of permanent magnets arranged in a circle. These magnets form paddles which, when the flywheel is revolving rapidly, churn the oil in the bottom of the oil well into a vapor and lift it up into the upper part of the casing. Near the top part of the flywheel cover there is a funnel from which a pipe is carried through the crankcase and into the front end of the oil pan casting.

The oil pan casting is divided into a series of troughs, which are moulded into the aluminum casting which forms this part of the engine. The pipe from the funnel leads directly into the foremost of these troughs. The walls of the troughs are all cast high enough to provide the proper level for the splash system to overflow when the oil rises high enough.

When starting on a trip the oil pan is filled to the level of the top of the trough walls and the flywheel casing is also filled to the level of the upper test cock, of which there are two located in the casing. The oil is poured in through a cup-shaped opening provided with a screen. It flows into the oil pan, down into the first trough, then, as more is poured in, it will overflow each successive trough wall, finally draining back to the flywheel casing. The top test cock is left open and oil is poured in until there is a flow from this test cock. The lower test cock is placed at the minimum permissible level.

The connecting rods splash into the troughs throwing the oil up into the cylinders, lubricating the walls and the wristpin. The camshaft is also lubricated by the splash. The excess oil drains back to the oil pan and flows gradually back to the flywheel casing.

There is a lead from the flywheel casing into the timing gears. The flywheel casing is also provided with a drain plug by means of which it may be emptied. The transmission and clutch are lubricated by the spray from the flywheel while the fanshaft and other bearings are provided with grease cups. The differentials and axle bearings are packed in grease.

Ohio System Contained in Crankcase—The Ohio motors are lubricated by a system which is contained almost entirely in the crankcase. The oil reservoir which holds about a gallon of oil is located in the lower half of the crankcase. The oil may be put into the reservoir in two ways: by pouring it through the breather tube or into the filler pipe which is located on the side of the motor.

Within the base of the crankcase and extending vertically there is a plunger pump, driven by means of an eccentric off the camshaft. This pump takes the oil from the base of the reservoir through a strainer tube projecting laterally into the reservoir and forces it up into the upper part of the lower half of the crankcase. This part of the crankcase contains a number of troughs into which the oil is fed by the pump in sufficient quantities to keep them constantly filled to such a height that a proper dip of the connecting rod into the oil will take place.

There is one of these troughs to each cylinder. As the rapidly revolving connecting rods are whirled into the oil pools contained in the splash troughs they churn the oil into a vapor which fully envelops the crankcase and lubricates every moving part contained therein. This includes the cylinder walls, connecting rod bearings, main bearings, camshaft bearings and cams.

After lubricating all the bearings the oil will drain back into the bottom of the crankcase and will pass through the system again, after being strained. A constant level throughout the crankcase maintained by means of partition walls placed laterally across the crankcase between each pair of cylinders.

Wheeler & Schebler Testing Equipment Discussed

Illustrating the freezing equipment that has been installed in the plant of Wheeler & Schebler at Indianapolis, Ind., for use in the testing of carbureters under varying conditions of temperature.

WHEN watches were first made it was found that they would not operate satisfactorily under varying conditions of temperature, and in the course of time a system was contrived for the adjusting of watches under conditions of heat, cold and position. It is a far cry from a watch to a carbureter in many ways, but there is no difference between watches and carbureters from the heat, cold and position point of view.

It was the idea of George Schebler when he built his first carbureter to so place the float that it would regulate the flow of gasoline to the nozzle, independent of position, taking into account the fact that when an automobile is going up or down a hill the "hydraulic grade" is disturbed from the level, and the flow of gasoline is accelerated or retarded accordingly, thus introducing a serious disturbing element, and Schebler thwarted the designs of this disturbance by placing the carbureter float concentrically with the nozzle.

A further study of the carbureter problem brought to Messrs. Wheeler & Schebler the idea that carbureters should be adjusted for heat and cold while they are being tested in the plant, taking occasion to make any changes in design that might be suggested by the use of suitable testing equipment, involving the questions of temperature. It was quite apparent that nothing substantial could be gained by them in these directions in the absence of a refrigerating plant, and Fig. 1 shows the interior of the refrigerating room with banks of piping P1, P2, P3 and P4 around the sides and upon the ceiling of the room with a thermometer T1 in the vicinity of the rollers, which are connected with a dynamometer located in the adjoining room. The walls of the room are suitably insulated, conforming to the customary practice in cold storage plants, and the equipment employed for the purpose is shown in Fig. 2, consisting of a compressor C1 driven by an electric motor with a controller C2, power being delivered from the motor by means of a silent chain in the manner shown in the illustration.

The refrigerating liquid enters the system through container C3, and a bank of condenser pipes C4 is placed on the side wall of the refrigerator R1, access to which is had by means of the double doors D1. The expansion valve V1 controls the flow of the refrigerating liquid after it is compressed and cooled and freezing starts at this point, delivering the expanded refrigerating medium through the pipe P1 to the bank of pipes within the refrigerator as referred to in Fig. 1. After the refrigerating medium passes through the bank of pipes within the refrigerator and its temperature is raised due to the absorption of heat from the chamber, it passes back to the compressor, where a new cycle of work begins.

The refrigerating equipment above described is contrived on a basis of flexibility, thus permitting the temperature of the refrigerated room to be varied over a wide range at will, and to reduce the temperature of the room to 10 or 12 degrees below frost is a fair possibility, thus making it easy to test carbureters under the conditions of cold as they obtain in the North in the Winter time, varying the same to the heat of the tropics through all the degrees of temperature represented in this wide range.

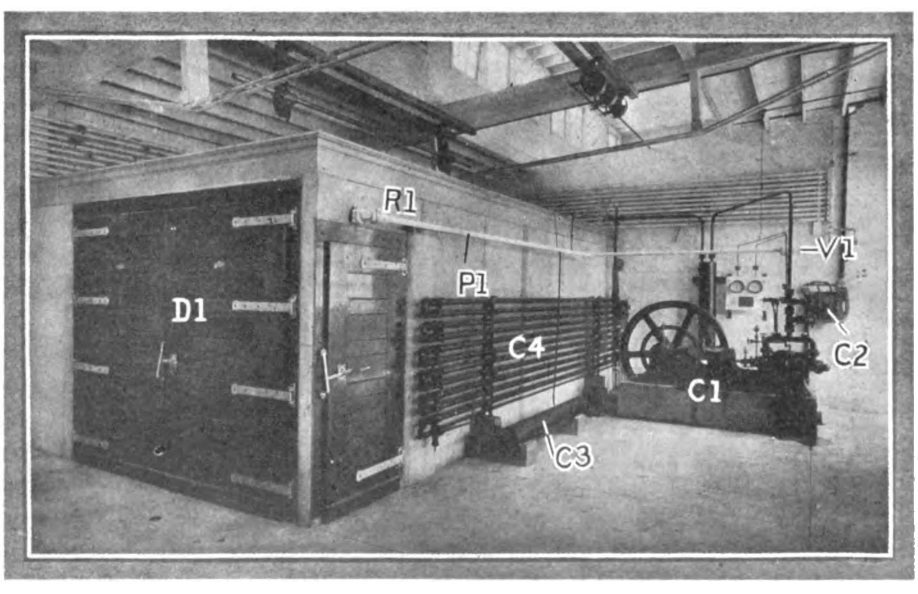

Fig. 2—Showing the compressor, condenser, method of driving the compressor, and scheme of piping the refrigerating medium into the refrigerating box

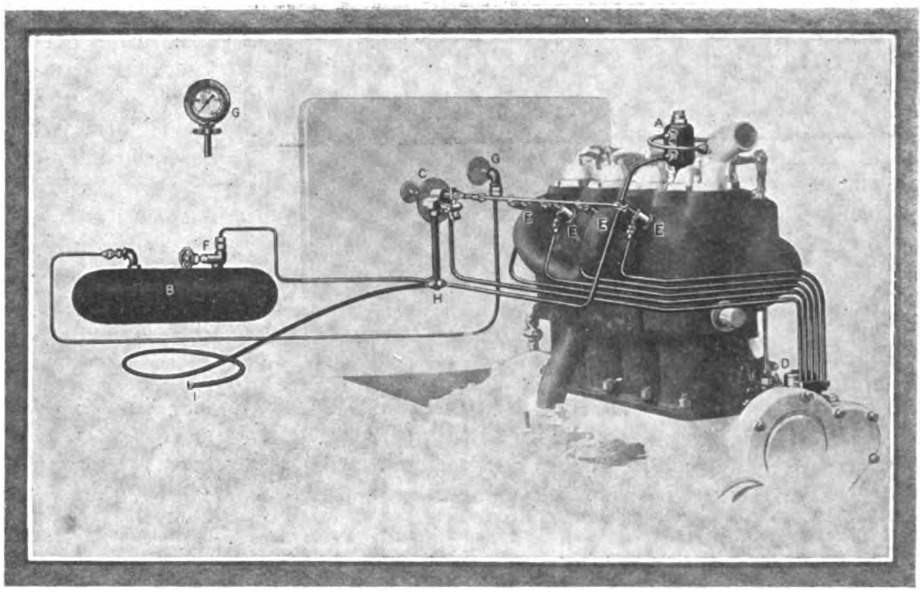
Chalmers Has Self-Starter

Illustrating and describing the self-starter that is being introduced by the Chalmers Motor Company, of Detroit, Mich., as a feature of 1912 Chalmers automobiles.

THIS starter is on the air pressure basis, the air being carried in the tank B with a capacity for air at the required pressure sufficient for the need. A check-valve A in the head of the No. 1 cylinder is responsible for the supply of air under pressure to the tank B which is carried beneath the body, supported by the chassis frame. Control is by means of a dash-valve C which releases the air from the tank B, piping being provided to carry the air as released to the distributor D, delivering the same in proper time to the respective cylinders of the motor for self-starting purposes. It is the function of the distributor to deliver the compressed air to the cylinders that are ready for the working stroke in their order of firing. Cylinder valves E, one for each cylinder, afford the means for the entry of the compressed air under the control of the timer to the respective cylinders. A shut-off valve F is placed at the tank B, and a pressure gauge G serves as a tell-tale, enabling the operator of the car to observe the condition of the tank from the pressure point of view. For purposes of inflating tires a valve H is cut into the system and a length of hose is provided with a tire-end inflater I at the extremity, thus completing the equipment. In a word, the motors as provided with this self-starting system operate as compressed air motors for a sufficient time to permit the gasoline equipment to get under way in case it does not respond to the first few revolutions.



Diagrammatic presentation of the Chalmers compressed air self-starter as used on 1912 Chalmers automobiles

BEER AND CHAUFFEURING DO NOT MIX IN LONDON—Automobile owners in London are in a ferment over the subject of "Chauffeurs and Public Houses." An alarmist has appeared in print with the statement that "a drunken motor driver is surely more dangerous than an intoxicated constable on duty, yet the latter is forbidden by law to drink in a public house, while the former can drink where and when he will. Many serious street accidents just lately have been due to intoxicated chauffeurs in charge of cars. Such mishaps could never have occurred had a little less liberty been given the drivers as regards the liquor they imbibed. Not that motor car drivers are all drunkards; but car driving, especially in London's congested streets, demands absolute sobriety to be at all safe. It would not be a bad plan to prohibit public houses from supplying intoxicants to uniformed motor car drivers when they are on duty."

Calendar of Coming Events

Handy List of Future Competitive Fixtures

Race Meets, Runs, Hill-Climbs, Etc.

July 5-22..........Winnipeg, Man., Fourth Canadian Competition for Agricultural Motors.
July 17-22.........Milwaukee Reliability Run, Wisconsin State Automobile Association.
July 20-28.........Minneapolis Reliability Run, Minnesota State Automobile Association.
July 22...........Guttenberg, N. J., Track Races.
Aug. 3-5...........Galveston, Tex., Beach Races, Galveston Automobile Club.
Aug. 4-5...........Brighton Beach, N. Y., Twenty-four-Hour Race.
Aug. 7............Chicago, Ill., Commercial Reliability Run, Chicago *Evening American.*
Aug. 12-18.........New Orleans-to-Memphis Good Roads Tour, New Orleans *Picayune.*
Aug. 12...........Philadelphia, Reliability Run, Quaker City Motor Club.
Aug. 12...........Worcester, Mass., Hill Climb, Worcester Automobile Club.
Aug. 17...........St. Louis, Mo., Reliability Run, Missouri Automobile Assn.
Aug. 25-26.........Elgin, Ill., Stock Chassis Road Race, Chicago Motor Club.
Sept. 1............Oklahoma, Reliability Run, *Daily Oklahoman.*
Sept. 2-4..........Brighton Beach, N. Y., Track Races.
Sept. 4............Denver, Col., Track Races, Denver Motor Club.
Sept. 7-8..........Philadelphia, Track Races, Philadelphia Auto Trade Association.
Sept. 7-9..........Hamline, Minn., Track Races, Minnesota State Automobile Association.
Sept. 12-13.........Grand Rapids, Mich., Track Races, Michigan State Auto Association.
Sept. 15...........Knoxville, Tenn., Track Races, Appalachian Exposition.
Sept. 16...........Syracuse, N. Y., Track Races, Automobile Club and Dealers.
Sept. 18-20........Chicago, Ill., Commercial Reliability Run, Chicago Motor Club.
Sept. ....Denver, Col., Track Races, Denver Motor Club.
Oct. 3-7...........Danbury, Conn., Track Races, Danbury Agricultural Society.
Oct. 7.............Philadelphia, Fairmount Park Road Race, Quaker City Motor Club.
Oct. 9-13..........Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 13-14........Atlanta, Ga., Track Races.
Oct. 16-18..........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.
Nov. 1.............Waco, Tex., Track Races, Waco Auto Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 4-6...........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9-11..........San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27-30.........Savannah, Ga., Vanderbilt and Grand Prix Races, Savannah Automobile Club.
Nov. 30...........Los Angeles, Cal., Track Races, Motordrome.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.

Foreign Fixtures

July 21-24........Boulogne-sur-Mer, Race Meet.
Aug. 6............Mont Ventoux, France, Hill Climb.
Sept. 2-11.........Roubaix, France, Agricultural Motor Vehicle Show.
Sept. 9............Bologna, Italy, Grand Prix of Italy.
Sept. 10-20.........Hungarian Small-Car Trials.
Sept. 16...........Russian Touring Car Competition, St. Petersburg to Sebastopol.
Sept. 17...........Semmering, Austria, Hill-Climb.
Sept. 17...........Start of the Annual Trials Under Auspices of *l'Auto*, France.
Oct. 1.............Gaillon, France, Hill-Climb.
Oct. 12-22.........Berlin, International Automobile Exhibition.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

WHEN the users of automobiles awaken to the fact that over 50 per cent. of the entire cost of maintenance of cars is due to bad roads, improperly maintained pavement, and, as General Bingham put it, to red tape, it will be time for them to dispense with the tape and to call upon the officials who are charged with the proper maintenance of streets and roads to do their duty or retire from office, in order that men of action may take their places. In the meantime, the presence of red tape in a governmental bureau is probably more effective to conceal graft than it is to facilitate work, and the mere fact that an office is incumbered with so much red tape that the men therein are prevented from doing their work is a sign that something is amiss, and history has proven that appropriations dissolve in the face of such propositions; but it cannot be said that the people get a return for the money that is levied upon them.

* * *

THOSE who advocate in a loud voice the building of good roads seem to confine their efforts to the mere building of roads, but when it comes to the matters involving the repairing and maintenance of these highways the great voices are silent and the roads fall into a wretched state of decay. The real question is, Do these advocates want good roads or are they looking for money? From the taxpayers' and the automobile users' point of view there is no sense in having good roads unless there is a proper system of maintenance so contrived and managed that the money invested in the making of good roads will be conserved by the maintenance thereof. As an illustration of the waste of public funds that cannot be tolerated much longer it is only necessary for the reader to travel on the Albany Post Road for a few miles out of New York, when he will discover that the road builder has been busy on maintenance work for upwards of two years with no better result than the obstruction of the narrow road by a traction engine and a stone roller. In the meantime the roads are so bad that the traction engine gets stuck in the mud, but we have not yet learned of any good that might have been derived by the expenditure of funds in this effort.

* * *

IT was only the other day that the Callan law was being reviewed by its author, who seems to harbor the impression that the law must have been a good one because he framed it, but he fails to appreciate the significance of the fact that this law was shot to pieces by the court and that it has so many imperfections in its make-up that even a one-day-old infant can legally drive an automobile if it so elects. We do not know who the "Senator" was afraid of, but he seems to have had an aversion to the framing of any automobile law that would compel the owners of automobiles to respect the rights of others, although workmen who make it a business to drive automobiles for others are compelled under this law to pay the cost of taking out a license, followed by an examination to show their fitness; but the funny part of it is that the examination as it is given to the average chauffeur would scarcely test the intellect of a scarecrow. That the automobile fraternity has had enough of the Callan law is a self-evident fact. That the public was ever infatuated with any of the provisions of this masterly piece of stupidity would be difficult to show.

* * *

WHEN side levers that are used in the sliding gears show that they are incapable of doing the work for which they are placed, and that they are fastened on to the shaft with nothing more than a screw, and if the automobiles so made are designated as 1912 products the man who buys one of them will know that the maker thereof has a poor appreciation of the value of truth, or that he is too stupid to be entitled to the patronage of any man of intelligence. In the meantime there is danger to the public in the operation of an automobile on the highways if the side levers are insecurely fixed to their shafts, and it is believed that the time will come when the law will take a hand on the side of safety in the building of automobiles if the makers thereof do the things that cannot be sanctioned on any fair count. There is a possibility that agents practice the art of delivering second-hand cars as new ones, and that they juggle the factory numbers with the idea of deceiving purchasers who might get the impression that an automobile must be a new one if it bears a high serial number. Fortunately for the automobile industry the examples of this sort that come to the Editor are relatively few, but they reflect discredit upon the automobile industry and they hurt, perhaps more than anyone else, the men who represent fair dealing. There should be some way to snub these flagrant violations of common decency, and the makers themselves should regulate such matters rather than have the right to do so taken out of their hands by legislative bodies.

Savannah Gets Blue Ribbon Events

Grand Prize, Vanderbilt and Small-Car Races

After much discussion it has been finally decided to award to Savannah the premier events of the American racing year. On Monday, November 27, the Vanderbilt, Tiedeman Cup and Savannah Trophy races will be run simultaneously over the 17-mile course, and on the following Thursday, Thanksgiving Day, the battle for the Grand Prize honors will take place.

THE uncertainty which has existed for some time as to the time and place for the running of this year's Vanderbilt and Grand Prize races was set at rest yesterday by the announcement that the first-named classic would be decided over the Savannah course on Monday, November 27, and that the latter event would be fought to a conclusion over the same course on Thanksgiving Day, November 30. Concurrently with the Vanderbilt Cup race will be decided the fight for the Tiedeman Cup and the contest for the Savannah Challenge Trophy.

The Savannah course, slightly altered from last year, is approximately 17 miles in length. The conditions of the Vanderbilt race call for 17 circuits of the course—about 289 miles; the Savannah Trophy event, 15 laps, and the Tiedeman Cup race, 10 laps. In the battle for the honors in the Grand Prize race the contestants will be compelled to encircle the course 24 times—approximately 408 miles.

The race for the Tiedeman Cup will be a stock car event, open to cars of 161-230 cubic inches piston displacement. For the Savannah Trophy event stock cars of 231-300 cubic inches piston displacement will be eligible.

The entry blank for the Grand Prize race is quite comprehensive. Among the rights reserved by the promoting organization is that of ordering an elimination trial in the event of the number of entries being too large for safety, considering the length of the course. American and foreign cars are eligible to compete, though not more than three cars of any one make can be entered. Foreign entries must be made through the recognized automobile club of the country in which the car is manufactured.

The entrance fee for one car is $1,000; two cars of the same make, $1,500; three cars of the same make, $1,750. Entries close November 15 with William B. Stillwell, care of the Savannah Automobile Club, Savannah, Ga.

Blazing the Way to the South

WASHINGTON, D. C., July 17—One of the worst highways in this country is about to be taken in hand and in order to stimulate interest among the townships en route from Washington to Richmond, Va., under the co-operation of the office of Public Roads, the Association of Highway Improvement and the Touring Club of America, three automobiles will leave here on Monday next, July 24, carrying Paul D. Sargent, acting director of the office of Public Roads; J. E. Pennypacker, secretary of the Association of Highway Improvement, and Leroy Mark, vice-president of the Washington branch of the Touring Club of America. Henry MacNair, editor of the Blue Book, will act as pilot to the party. Meetings will be held along the line at the various stopping places. The road at the present time from the capital to Richmond is 179 miles, which would be considerably shorter were it not for the numerous detours that have to be made. Richmond has been chosen as the scene of the first National Highway Conference, which will be held in October of this year.

Overlapping Shows Will Crowd Metropolis

The selection by the National Association of Automobile Manufacturers, Inc., of January 10th to 17th as the dates of its show at the Grand Central Palace, and the combining of passenger and commercial vehicles in one show, will assure New York a full representation of automobile enthusiasts during the weeks in question. The Garden show opens on January 6th and closes on January 20th. The dates of the National Association show will, therefore, coincide with the last four days of the first week and the first three days of the second week of the Garden show.

It was not the intention of the National Association to ask the Motor & Accessory Manufacturers to participate, because it felt that its members would have enough to attend to with the Garden show. The Motor & Accessory Manufacturers soon made it plain, however, that it would expect to be admitted, and on Friday last arrangements to that end were completed. The Motor & Accessory Manufacturers will occupy 20,000 square feet of space on one of the upper floors.

M. C. A. to Meet in Detroit August 10-11

At the annual meeting of the Manufacturers' Contest Association, which will be held in Detroit, August 10 and 11, one of the most important matters to come up for discussion will be the establishment of a new method for determining the weight limits in stock car events. Various other interesting subjects will be considered, among them the important matter of regulating competitions held on half-mile and one-mile tracks which were built originally for other than automobile contests. The association membership roll now includes 91 members.

Guttenberg Races to Be Run July 22

Inability to get the track in condition in time, coupled with the failure of several racing stars to send in their entries owing to previous engagements, induced the promoter of the race meet scheduled for Guttenberg track on Saturday, July 15, to ask for a postponement of one week. The request was granted by the Contest Board, and the races will be run off on Saturday, July 22. Entries have been received of Mercer, Simplex, E-M-F, Overland, Lancia, Baby Regal, Correja, Schacht, Marmon, National, Mercedes, Abbott-Detroit, Pope-Hartford, Pullman and Buick cars.

Brighton Beach 24-Hour Race Postponed

Having found it impossible to secure ten entries for the 24-hour race scheduled for Brighton Beach track on August 4, Promoter Moross has announced the postponement of the event till September 2 and 4, when an attempt will be made to feature it as a wind-up to that meeting. If this is found inexpedient the long race will be still further postponed.

Chicago Orphans' Outing

The four automobile organizations of the Windy City, donating 173 cars, unite in entertaining over 1300 little ones and 100 inmates from the Home for the Aged with a 30-mile ride over the breezy boulevards of the Western metropolis, with occasional stops in the parks for refreshments.

CHICAGO, July 17—Local motorists gave the orphans and old people their annual ride Friday, when more than 1,300 children and 100 from the homes for the aged were taken out by the four local organizations, the Chicago Automobile Trade Association, the Chicago Motor Truck Association, the Chicago Motor Club and the Chicago Automobile Club. Chicago holds its outings later than other cities in order to be sure of the weather, and the wisdom of this course was apparent yesterday. No. long stops were made at any of the summer parks. Instead the old people and children were put into 160 pleasure cars and thirteen trucks and taken for a ride over the boulevards. They went north first and a stop was made in Lincoln Park, where ice cream cones were handed out to everybody. Then the cars headed south and swinging through the two big parks stopped at the German building in Jackson Park, where more ice cream cones were handed out, after which the parade disbanded.

In all the cars were out 3 hours, in which time they covered something like 30 miles. No mishaps marred the afternoon and the children and old people all had a good time. It is a matter of note that all the children and old people were cared for, there being fourteen local institutions represented in the run. More than enough cars were provided. It was discovered that some of the institutions, evidently anxious that none of the children be overlooked, reported they had more than they really had. One instance noted was where 175 children had been reported, whereas there were only 125 when the cars called.

Credit for the outing belongs chiefly to Dr. H. A. Gunther and John H. Kelly, chairman and secretary respectively of the joint committee representing the four organizations, who worked night and day for a week to complete the arrangements.

Quakers in Row with Mayor Over Fairmount Park Race

PHILADELPHIA, July 17—Owing to Mayor Reyburn's antagonism to the Quaker City Motor Club and his announced dissatisfaction with the organization's management of the Eastern classic last year, vigorous competition for the honor of conducting the fourth annual 200-mile Fairmount Park road race has developed, and although the Quaker City Motor Club has secured the sanction, the Philadelphia Automobile Trade Association put in a formal application to the Fairmount Park Commission at its monthly meeting yesterday for permission to hold the race. Owing to the fact that the contest cannot be held without adequate police protection, which of course would not be granted the Quaker City Motor Club in case the Mayor should persist in his opposition to the club, the automobile fraternity is up in the air as to the ultimate outcome. Despite Mayor Reyburn's indorsement of the Philadelphia Automobile Trade Association, members of the Quaker City Motor Club feel sanguine and are confident that the misunderstanding engendered between the Mayor and the club last year over the distribution of the receipts will be adjusted satisfactorily to their organization, the necessary police protection afforded, and the event conducted as in the past. The Q. C. M. C. is already armed with a permit from the Park Commissioners, in addition to the official sanction of the automobile governing body. Less than three months off, interest is already rife over the big event and a final decision from the city's chief executive is eagerly awaited.

Saturday, October 7, is the scheduled date for the race.

Planning Trans-State Highway in Texas

GALVESTON, TEXAS, July 17—For the purpose of looking over and ascertaining the best route for the proposed highway from the northern boundary of Texas across the State to the Gulf of Mexico, a party occupying three automobiles left the Red River on July 10 for Galveston. The general idea is to construct across Texas from the Red River to Galveston a splendid highway, and then to encourage the adjacent counties to build good roads to connect with this highway.

Good Roads Train to Tour Virginia

RICHMOND, VA., July 17—Automobilists throughout the State are gratified over the announcement of the Southern Railway that the good roads train of that system will tour the State. This train, which has just completed a tour of Alabama, Mississippi and Tennessee, has just entered North Carolina, and after traversing that State will come into Virginia, and will be here in Richmond on October 30-31 and November 1, at which time the National Good Roads Association will be in session here.

Fig. 2—Line-up of automobiles that took place in the event—there were over one hundred and seventy of them in the affair

The good roads train is composed of three exhibition cars. Daily lectures are given by expert road men, illustrated with stereopticon views, charts and maps, showing the progress of good roads movement throughout the South.

Ohio Second in Automobile Registrations

According to figures given out by the State Automobile Department, Ohio ranks next to New York in the number of automobiles owned and registered. Ohio now has 40,131 machines and New York 69,000. Pennsylvania trails along with about 39,000, with Illinois and Indiana a tie for the fourth place with about 35,000 each.

Seventeen Entries So Far for Elgin Races

CHICAGO, July 17—With seventeen entries actually in for the American Automobile Association's national stock chassis road races on August 25-26, the Chicago Motor Club and the Elgin Automobile Road Race Association believe they will gather a field that will be larger than the one that went to the tape last year.

Entries of four Nationals and a Corbin were received Saturday, while to-day's mail brought in three Alcos. Besides these, the entries of three Falcars, as many Staver-Chicagos, two Coles and a Lozier had already been received.

The following trophies are offered for competition on August 25: Fox River Trophy, for stock chassis, 161 to 230 cubic inches piston displacement, minimum weight 1,200 pounds. Distance 137 miles. Kane County Trophy, for stock chassis, 231 to 300 cubic inches, minimum weight 1,500 pounds. Distance, 170 miles. Illinois Trophy, for stock chassis, 301 to 450 cubic inches, minimum weight 1,800 pounds. Distance 202 miles.

Fig. 3—Chicago orphans leaving Lincoln Park, where thirteen hundred kids enjoyed their first treat of ice-cream cones

The big event, for the Elgin National Trophy, valued at more than $3,500, will take place on the following day, August 26, and as this event is open to stock chassis of under 600 cubic-inch displacement it is therefore open to those cars which will have competed in the three events on the previous day. In addition to the four handsome silver trophies big cash prizes will be awarded the successful drivers.

So far as the course is concerned, there is little left to do. Oiling has been going on for a week now and within the next few days the circuit will be inspected for faults that will be remedied before practice begins if any are discovered. The course has been very much improved and considerably widened, especially in the home stretch and at the turns. The bad Udina Turn has been widened until it is now 100 feet across.

1912 models will be eligible for the events provided stock certificates of descriptions are filed with the Contest Board on or before July 27 and are accepted by the Technical Committee, who will have charge of the technical affairs at Elgin.

Booming Des Moines as an Automobile Center

DES MOINES, IOWA, July 17—"Make Des Moines the automobile distributing center of the West." This was the keynote of a big banquet participated in at the Hyperion Field and Motor Club Friday night when prizes and cups won in that club's "Little Glidden tour" were presented. W. E. Moyer, pathfinder for the tour and the man whose efforts are largely responsible for the tour, sounded the keynote and the sixty automobile men who were present enthusiastically pledged themselves to do their best to bring his prediction to pass.

Fig. 4—Chicagoans stopped, looked and listened wherever the orphans' merry army passed on its way

Fourteen cups which were won in the four-day, 450-mile endurance contest were presented by Earl Butler, referee of the contest.

D. S. Kruidneir, Des Moines agent for the Cadillac, drew the sweepstakes trophy, his car having finished without a penalty in either the road or technical tests. All three of the Des Moines daily newspapers presented cups.

Automobilists of Iowa are to meet in Des Moines this week, July 20, in an attempt to form a closer State organization to promote the interests of good roads. The meeting is called by H. B. Groves, vice-president of the Iowa Automobile Club, and practically every auto club in the State has been asked to send representatives. It is thought that several hundred will attend.

Although there is a big automobile show to be held at the Iowa State fair, the last week in August, Des Moines automobile dealers are already beginning to lay their plans for the third annual show of the Des Moines Automobile Dealers' Association which is to be held at the Coliseum next Spring. It is likely that the affair will be pulled off the middle of March, although no definite dates have yet been fixed. W. E. Moyer and C. G. Van Vliet, who managed the 1911 show, will in all probability be in charge.

Cost of South Bend Auto Patrol Wagon

SOUTH BEND, Ind., July 16—At the request of the city administration Wilson E. Snyder, clerk of the Board of Public Safety, has prepared figures on the comparative cost of the auto patrol, which was placed in commission six months ago. During the six months it has been in use 1,010 arrests have been made and 2,504 miles covered. In the 12 months of 1909 there were 1,651 arrests and 2,927 miles covered by the horse-drawn patrol. The investment in horse and wagons and paraphernalia in 1909 was put at $1,527, and the interest on the investment at 6 per cent., with the cost of operating for the year was $1,101.80. In contrast is put the cost of operating the auto patrol for six months. Included in the figures is the cost for 27 days of last December. Investment, $4,831.50; interest on the investment at 6 per cent. for six months, $144.94; supplies, $27.85; lubricating oil, $21.25; hard grease, $6.75; gasoline, $59.36; repairs, $37.26; total for six months, $297.41. Estimated cost for operating for one year, $594.82. Cost per mile run under the old system, 37 1-2 cents; with auto patrol, 12 cents.

Doyle Joins the Timken Force

P. W. Doyle has severed his connection with the Long Manufacturing Company and on August 1 will join the sales department of the Timken Roller Bearing Company, of Canton, Ohio, and the Timken Detroit Axle Company, of Detroit, Michigan.

Cleveland Reliability Starts in Heavy Rain

CLEVELAND, O., July 18—With the sky black with clouds and in a pouring rain the 40 cars entered in the Cleveland *News* three-day reliability run left the Hollenden Hotel this morning promptly on schedule time. Many thought that because of the down-pour of rain the run would be postponed, but as all the contestants were willing to start the leader was sent away on time, the remaining entrants starting at three-minute intervals.

Mrs. Fred. C. Wood, the only woman driver in the run, laughed at the rain and started out with a seven-passenger Oldsmobile as a non-contestant. She carried her husband, two other men and two women and was given a great ovation as she pulled out.

Because of the rain that had fallen almost continually in the last 20 hours the drivers have had great difficulty in making the run on schedule time. Though the best roads were picked out for the route the rain has played havoc with more than one of them.

After plowing through mud and climbing rough hills the contestants arrived at Youngstown shortly before noon and were greeted by a great crowd that had gathered in the square. The stop marked the completion of the first 68 miles of the 533-mile trip. With the exception of a few punctures all the cars participating in the run went through without a breakdown of any sort.

The rain which had been falling in torrents let up during the morning and although the roads were very muddy and a number of drivers were obliged to put chains on their wheels, good time was made.

Farmers and their families greeted the contestants from every doorstep on the way, and at Chagrin Falls, Warren and Niles the citizens that had gathered in the town streets cheered the cars as they passed.

Tired, hungry, dirty, but enthusiastic, the contestants pulled into Wheeling Monday night completing the first day's run, which was equal to 212 miles.

With new supplies of gasoline and oil the contestants checked out of Wheeling, W. Va., at 7:30 in the morning, Tuesday, the second day of the tour.

At one o'clock Tuesday afternoon 25 of the contestants checked in at Zanesville. The van of the tourists reached Newark at 4 p. m.

Following is a list of the contesting cars:

No.	Car.	Driver.
1	Columbia	C. H. Tyler
2	Maxwell	C. G. Bleasdale
3	Velie	D. W. Iseminger
4	Velie	Harry L. Lance
5	Oldsmobile	Andy Auble
6	Oakland	Fred Krum
7	Cadillac	Tom Swan
8	Krit	John Rauch
9	Brush	E. McCoy
10	Firestone-Columbus	Harry Kortz
11	Garford	Ira Fouche
12	Buick	F. B. Smith
13	Jackson	C. D. Paxson
14	Regal	L. B. Moore
15	Regal	G. P. Sperry
16	Marmon	I. H. Greenwald
17	DeTamble	H. W. Orndorf
18	Abbott	R. E. McClellan
19	Peerless	T. S. Hammer
20	Bergdoll	F. A. Kaiser
21	Oakland	H. Bauer
22	Everett	J. Gardham
23	Stuyvesant	P. H. Brown
26	Cartercar	V. R. Hall
27	Krit	H. Higginbotham
28	Lion	H. Bloomstron
29	Norwalk	F. Taylor
30	Norwalk	T. J. Ruffel
31	Ford	F. E. Van Paton
32	Ford	A. H. Smith
33	Ford	H. J. Lytle
34	Mitchell	E. C. Lucas
35	American	C. Kagy
36	Van Dyke	F. J. Monsette
37	Reo	A. G. Bredbeck
38	Maxwell	G. A. Roberts

Albion and Vaterland Tour Together

By the time that these lines appear in print the Prince Henry Trophy Tour will have been completed, and what is known as the Coronation Tour will have added another event to the history of the automobile movement. There was no attempt at a race this year, and the trade element was done away with, as the cars were identified by the names of their owners and not by the official name of the car.

WITH rumors of strife on the one hand the Teutons and Britishers have been mingling together in automobiles vying with each other for the supremacy of the road. The Prince Henry of Prussia Trophy is this year being competed for by members of the Imperial Automobile Club of Germany and the Royal Automobile Club of Great Britain and is a tour pure and simple. There is no semblance of a race and the cup is to become the property of a club and not an individual. In other words, it is an inter-club run over two kingdoms, the participants necessarily being members of either of the aforementioned clubs. Penalties will be inflicted for time delays at the rate of one mark for every five minutes. The replacement of a spare part necessitates the loss of 12 marks for every part replaced. Additional gasoline that may be required during the day after the start will be counted as a mechanical stop, but 30 minutes are allowed before the start for lubrication and replenishments and adjustments, after which the hoods will be sealed. The cars must be fully equipped with wind shields, tops and speedometers, and the regulations call for special regulations regarding body work in order to compell the entrants to use recognized patterns.

The German team entries total 42 while those from Great Britain number 30. The cars are entered by individuals and to eliminate the trade element the names of the cars are with-

A—Map of Great Britain, showing the route covered by the participants in the Prince Henry tour

B—Prince Henry of Prussia, driving his own car, starting the tour at Homburg

C—Duke of Connaught's car at the start of the tour held from official publication. Army and naval officers of the respective nations will act as observers on the cars.

The illustrations depict the scenes at the start, the first car to leave being that of Prince Henry, with the Prince at the wheel. Homburg was chosen as the starting point and it will be remembered that this has been the venue for several memorable speed races including the Gordon Bennett, when the French wrested the blue ribbon of the road from their German "friends" who had won it the year previous from the British over the roads of the Emerald Isle.

The old Gordon-Bennett course was followed as far as Königstein where the route bears due north as far as Leun, and afterwards follows the course of the river Lahn as far as Limburg, whence the road leads via Montabur to Coblenz. From Coblenz to Cologne, and from Cologne to Wesel, the course of the Rhine was followed, but from Wesel the route takes an easterly direction to Münster, famed for its old Rathhaus and plethora of churches, thus avoiding the Dutch frontier.

Cologne was the stopping-place on the night of Wednesday, July 5th, and the cars halted at Münster on the night of Thursday, July 6th. From Münster the direct route leads to Bremerhaven, on the mouth of the Weser, where the vehicles were taken on board a steamer specially chartered for the purpose of their conveyance to Southampton. On the night of Friday, July 7th, competitors slept on board, and also on the Saturday night; the steamer arriving in port on Sunday, July 9th. On the following day, Monday 10th, a start was made from Southampton due north through Winchester, Whitchurch, Oxford, and Stratford-on-Avon to Leamington, this being the first stop on English soil. From Leamington, still traveling north, the manufacturing towns of Leicester, Nottingham, Worksop, and the racing centre of Doncaster were taken *en route* to the famous inland watering town of Harrogate. Here the competitors stopped over Tuesday night, July 11th.

Leaving Harrogate, a detour was made through Thirsk, Helmsley and Easingwold in the Yorkshire moors before proceeding on the main road through Northallerton and Darlington to Newcastle-on-Tyne, the engineering centre of the north. Still following the Great North Road the cars passed over the Scottish border on Thursday, July 13th, and reached Edinburgh that night. Here, also, the competitors stayed over the whole of Friday, July 14th.

Edinburgh is the northernmost point on the route, so that on Saturday, July 15th, the southward journey commenced; its immediate destination was Windermere, Saturday night and the whole of Sunday, July 16th, was spent in the Lake District, and on Monday the two clubs continued to travel due south as far as Shrewsbury, where the night of Monday, July 17th, was spent. Having thus traversed the north-eastern border of Wales, the route continues due south through Ross and Chepstow, and then follows the banks of the Severn through Gloucester to Cheltenham, which was the destination on Tuesday, July 18th, and the last night away from home. From Cheltenham the route goes for a short distance due south in order to strike the Bath road at Chippenham, and then turns due east along this famous old coaching highway. The completion of the run was the occasion of a banquet at the Royal Automobile Club on Wednesday evening, July 19th.

Twenty-six Contestants in Wisconsin Tour

MILWAUKEE, WIS., July 17—Twenty-six cars left Milwaukee this morning on a trip of practically 1,000 miles, the result to determine the awards by the Wisconsin State A. A. of four trophies donated to the organization by newspapers and individuals interested in motoring and the promotion of sportsmanship. It is the second annual reliability tour of the Wisconsin State A. A., the first being held from July 18 to 23, 1910. Emil Hokanson, whose car won the only trophy offered in 1910, by making a perfect score, is defending his honors in another Buick, a 1911 model.

The contestants in the trade or professional division are: Cadillac, three Buicks, two Imperials, Reo, Ford, Krit, Case, National, Overland, Franklin, Regal, Warren-Detroit and Petrel.

There are nine roadsters and seven touring cars in the trade class and two roadsters and two touring cars in the private class.

There are eight official cars, as follows: The official Kissel Press car; pilot, Overland, 53; confetti car, White Gas, 40; general press, Rambler, 63; pacemaker, Cadillac; technical car, Case; secretary's car, Palmer-Singer; physician's car, Buick, 21.

Premier Tourists Pass Through Omaha

OMAHA, NEB., July 17—The Philadelphia tourists in Premier cars who are touring across the country were in Omaha from Monday evening to Wednesday morning, July 12. Coming through Iowa they found it fine going, until a heavy rain on Sunday made the progress considerably slower. In Omaha they purchased a camping outfit, and they expect to camp out overnight many times while they are in the mountains. There were still twelve automobiles and thirty-eight tourists in the party.

Some of them expressed mild surprise at not seeing the Indians running loose in Nebraska.

Wisconsin's New Law Goes in Effect Aug. 1

MILWAUKEE, WIS., July 17—The Wisconsin Legislature has passed the consolidated motor-car bill and it has received the signature of Governor McGovern. The chief changes are as follows:

Annual registration, instead of present perpetual registration while car registered is in the hands of its then owner.

Annual fee of $5.00 for registration. Present fee is $2.00 for perpetual license. Proposition to tax by horsepower turned down.

Two licenses must be carried, front and rear. Only one necessary heretofore. The tags are furnished free upon payment of registration fee.

Red tail light must be carried in addition to one light on front as at present.

Speed limit in cities changed from 12 miles per hour to 15 miles per hour; in country, 25 miles per hour as at present. Proviso is included that no greater speed shall be used anywhere than is safe under the circumstances and conditions.

No person under 16 years of age may operate a motor vehicle, unless accompanied by a responsible adult.

Each city and village clerk must keep an up-to-date list of motor car and cycle owners, in booklet form, to be furnished by the Secretary of State and to be accessible to free inspection during business hours.

After paying the expenses of the department of the Secretary of State's office which attends to the registration work, three-fourths of the money accruing from the registration fee collection shall be transferred to county treasurers to be used in the repair of country highways, and the remaining one-fourth shall be used to augment the State highways fund.

A second offense against speed regulations shall be punishable by fine of $25 to $100, or imprisonment in jail not more than 60 days, or by both fine and imprisonment, at the discretion of the court.

No city, village, county, town, park board or other local authority shall have the power to pass any law or regulation interfering with or contrary to the State law.

Manufacturers are to have assigned to their testers a distinguishing number or letter, and this number or letter must be used whenever factory cars are driven on streets or highways of the State.

Any driver inflicting an injury to any person must stop and offer assistance and must always give name and address if requested. Failure to do either lays the offender liable to a fine of not more than $100 or imprisonment for a term of not more than three months.

The new law goes into effect August 1. While present licenses are good until January 1, 1912, all cars registered after August 1 come within the new law and a fee of $5 must be paid.

Winnipeg's Show Is Quickening Trade

WINNIPEG, July 15, 1911—Western Canada is being saturated with information relative to the automobile, its efficiency and field, in this new country. The occasion is the second automobile show to be held in the West of the dominion and it is being held in connection with the twenty-first annual Winnipeg Industrial Exhibition. The machines of approximately seventy-five factories of United States and Canada occupy 40,000 feet of floor space in the manufacturers' building at the fair.

As an opportunity for meeting the successful townsmen and farmers of Western Canada the fair is without any equal. It draws from fifty to sixty thousand outside residents every year. During May the directors decided that the inception of an automobile exhibit might interest its patrons. The notice was published and within a week the 20,000 feet allotted was subscribed by agencies and manufacturers. A further allotment was made and entered for and ultimately the directors had to rush up a wing of 10,000 feet to hold the over-flow.

Since the opening day of the fair the automobile show has been the biggest feature of the exhibits. In all uncovered territory to the west agents are being appointed at the grounds and in addition hundreds of prospective purchasers are being listed. The local automobile and supply men state that the show is the best thing which has been held in the interests of the automobile in the west, exceeding even the winter show under the auspices of the Motor Trades Association.

Among the cars shown are the Chalmers, Mitchell, National, Ford, Buick, Packard, Overland, Hupp-Yeats, McFarlan, Inter-State, Republic, Shackt, E.M.F., Halladay, Hudson, Knox, Columbia, Maxwell, Patterson, Gramm trucks, Everitt "30," Paige-Detroit, Henry, Marathon, White, Warren, Brush, Gopher truck, Russell, Waverly, Olds, Reo, Detroit-Electric, Winton, Case, Speedwell, K-R-I-T, Hupmobile, Kissel, Empire and several others. In addition to these displays, dealers in accessories and supplies occupy several stands.

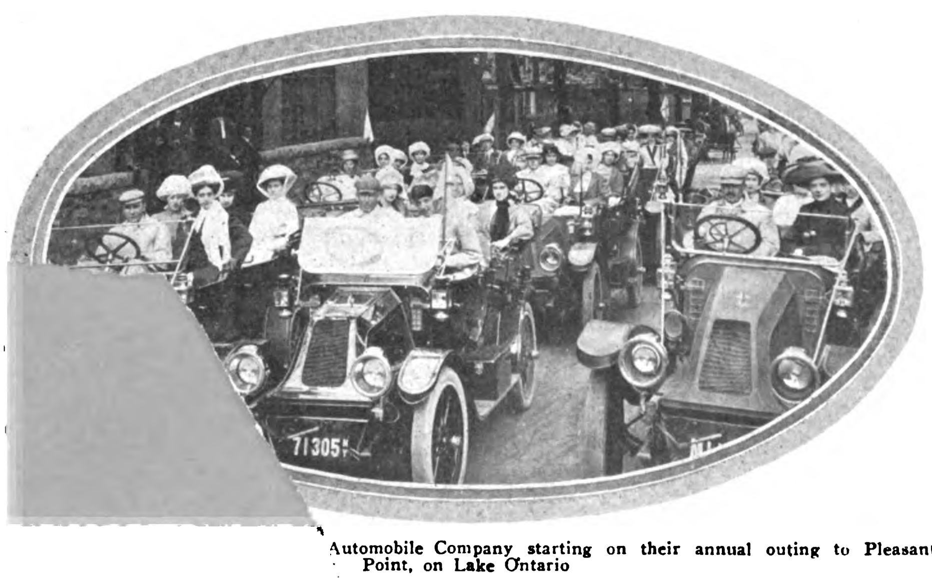
New Use for the Automobile

During the recent heated spell in New York City in which over a thousand horses were incapacitated, several members of the New York Woman's League for Animals patrolled the hot streets in their automobiles in readiness to see that proper care was given to the beasts and that no overloading of the vehicles drawn by them was taking place. Due to the activities of this branch of the society, several arrests were made and convictions secured.

This league, which is doing remarkably good work, was formerly the Woman's Auxiliary to the Society for the Prevention of Cruelty to Animals, but since the object of the society is not so much correctional as to come in more intimate touch with those who own animals for pets or otherwise, a separate society has been formed.

150 Owners of Automobiles in Bozeman, Mont.

A considerable number of the most influential owners of automobiles in Gallatin County around Bozeman, Montana, are having meetings for the purpose of organizing an automobile owners' association, and Charles E. Dunlop, secretary of the Bozeman Chamber of Commerce, is authority for the statement that there are 150 automobile owners in that county, and that they are all in favor of a virile organization devoted to the interest of automobile owners.



Automobile Company starting on their annual outing to Pleasant Point, on Lake Ontario

The Week's Doings in Detroit

DETROIT, MICH., July 17—Continued interest in long trips by motor trucks is noted locally. The Van Dyke delivery wagon which led the Affiliation tourists over the 800 miles of their run has been sent to Cleveland to take part in the Cleveland *News* run. The Saurer trans-continental truck passed through Detroit several days ago on its return trip to New York. Local manufacturers of trucks and wagons are almost daily sending their cars out into the country on trial trips. In addition, many of them are using factory-owned cars as demonstrators for local merchants' use. It has become generally recognized that the most effective form of salesmanship is found in this method. Rarely does it occur that a merchant consents to a demonstration of this character, without following the demonstration with an order for cars. The presence of the factories in Detroit has made demonstrations of this sort particularly applicable to the local situation and there is a marked increase in the number of delivery wagons and trucks, in active use this season, on the downtown streets.

One of the busiest factories in Detroit just now is that of the Brush Runabout Co. It is declared that contracts for the new Liberty-Brush have been closed during the past two weeks at an average of faster than 100 a day. The factory is producing 80 a day and this week started a night shift which will endeavor to keep up with the orders which the firm is receiving for the new car. The company is now engaged in the tabulation of a remarkable economy contest, conducted July 4 among its dealers all over the country.

James T. Shaw, treasurer of General Motors Co., is back in Detroit, after a two-weeks' tour in which he gave the company's new Welch-Detroit car a thorough test. Mr. Shaw made several detours in search of strenuous hill-climbing tests and found the car equal to everything asked of it.

The younger manufacturing firms still continue to find difficulty in securing representation, particularly in the smaller cities of the country. It is a generally admitted fact that there are fewer dealers in the country now and fewer additions this season than at any prior time in recent years. On the other hand, those dealers now in the business are virtually all of them well established and financially capable.

Detroit parts-makers and manufacturers of special machinery all feel the prosperity of the busy season and many of them are increasing their equipment. There will be several additions to their ranks next year, prominent among which will be the Henry & Wright ball-bearing drill press plant, which now has a building in process of erection near the plant of the Hudson Motor Car Co. The Cross Gear and Engine Co., 800 Bellevue avenue, has recently increased its capital stock from $20,000 to $80,000 and will materially enlarge the capacity of its plant.

The King Motor Car Co., which has 22 acres of land in the Jefferson avenue district and already has a factory building that is busy turning out cars, will soon break ground for an extensive addition. The firm has enlarged its orders for material and expects to build 3,000 cars of the 1912 model.

Stephens Heads Federal Rubber Co.'s Chicago Branch

CHICAGO, July 17—George W. Stephens, formerly manager of the American Tire & Rubber Company of Chicago, and at one time advertising manager for the G & J Tire Company of Indianapolis, has been appointed manager of the Chicago branch of the Federal Rubber Manufacturing Company of Cudahy, Wis.

Timely Hint for New England Tourists

The Touring Club of America suggests the following directions for avoiding the road construction between Pittsfield and Albany:

Mileage

0.0 Start Berkshire Hills Branch T. C. A. Hotel Wendell, Pittsfield, proceed on Blue Book Route 337 to Shaker Village.
4.6 Turn left (big white house on right).
6.9 Pass cross-roads, cemetery on left.
8.1 Turn right on dirt road, bear right.
10.7 Pass cross-roads, straight ahead, bear right, mill pond on right.
11.5 Pass white church on right.
11.8 Turn sharp right, Queechy Lake on right.
13.3 Bear left continuing to
16.7 New Lebanon, turn left passing white church direct onto oiled State road to Albany—follow Blue Book Route 337.

Dorian Sales Force Reorganized

Mr. James T. Wallace has been made general sales manager of the Dorian Remountable Rim Company, with headquarters at 114 Liberty street, New York City. A. C. Marquardt will be Mr. Wallace's assistant. J. Franklin Duffy has been placed in charge of the Broadway office at No. 1804. The factory of the company has been removed to the Bush Terminal in Brooklyn.

Electricity for the Man Who Wants to Know

Among the books of recent issue our attention has been called to "Practical Applied Electricity," from the pen of David Penn Moreton, B.S., E.E., associate professor of electrical engineering at Armour Institute of Technology; press of Reilly & Britton Company, Chicago; 438 pages, including index, in flexible morocco, adequately illustrated and carefully compiled. The price of this book is $2, which is not too much to pay considering the fact that the whole range of electrical activities is brought within the narrow view of the reader who cannot afford the time it takes to obtain a substantial groundwork in technical literature. This book should be of value to the automobilist on account of the excellent information it gives in relation to batteries, and the fundamental principles of electricity, affording to the reader a clear understanding of the basic principles of every electrical device employed in automobile work. True, the book holds a wide measure of definite information that cannot be of great service to the mere owner of an automobile, but it is plainly put and it might prove of value as well as interesting to the owner of a car who will devote a little time to the reading of this handy volume.

New Things Among the Accessories

Combination Electric Ignition and Lighting System

THE Matchless electric lighting and ignition system for automobiles and motor boats, manufactured by the Esterline Company, Lafayette, Ind., possesses some very unique features.

The equipment comprises a positively driven, magneto-type, direct-current generator, a storage battery and an automatic, self-closing, low-voltage, release, overload, reverse current controller. The generator is made to connect directly to the pump shaft in the same manner as an ignition magneto, without the use of a speed governor or speed-controlling device. It is supplied with complete ignition equipment, which can be omitted if desired, so that the ignition magneto can be retained or dispensed with, as the user may desire. If desired, the generator may be driven by gears or a silent chain, in case the ignition equipment is not used.

The use of a permanent magnet generator is made possible by the unique electric controller which comprises a part of the system. The controller has four distinct functions, as follows:

(1) To connect the battery to the generator when the voltage of the generator has reached the point where it will charge the battery.

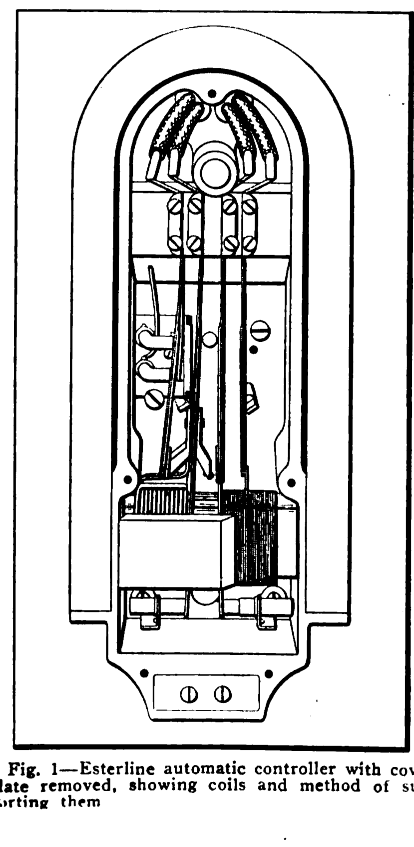

Fig. 1—Esterline automatic controller with cover plate removed, showing coils and method of supporting them

(2) To limit the current through the battery to the normal charging rate, when the generator is running at high speed.

(3) To disconnect the battery from the generator whenever the voltage of the generator is less than that of the battery.

(4) To prevent the connection of the battery to the generator when the car is driven backward.

The controller consists essentially of a

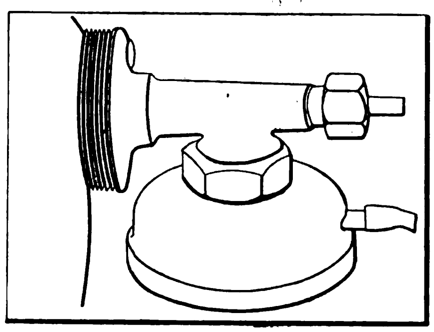

Fig. 2—Automatic pressure regulator on P. & B. acetylene gas-lighting system

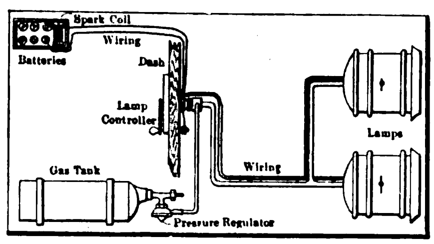

Fig. 3—Diagram of installing P. & B. illuminating scheme

die-cast metal case, over which is placed a permanent magnet, with pole pieces projecting into the case; a pair of coils surrounding the pole pieces, but capable of motion relatively to the pole pieces; a cover plate, which seals the case tightly, rendering it dust- and moisture-proof.

The force moving the coils is obtained by the reaction between the field of the magnet and the current in coils surrounding the projecting pole pieces.

All of the moving parts of the controller are mounted on phosphor bronze leaf springs, 1-2 inch wide, set rigidly in an insulating block.

The operation of the controller is such that all electrical circuits are opened and closed at the instant the current is zero. No current is drawn from the battery by the controlling apparatus.

With the car at rest or running at slow speed, the connection between the battery and the generator is open, but when the voltage of the generator becomes sufficient to charge the battery, the circuit between the battery and the generator is closed.

The space occupied by the controller on the dash is 2 1-2 inches x 6 inches, and it extends only 1 1-2 inches from the dash; the weight complete is 2 1-2 pounds. The metal case is water-proof, dust-proof and ornamental in appearance.

A four-point, back-connected switch is used, with the stem extending through the front of the controller case. There are four positions of the switch—lights off for day running, side and tail lamps for city streets and use while the car is standing at night, head and tail lights for touring and all lights on.

All wiring is on the engine side of the dash, where it is not exposed to view. Openings are provided in the front of the controller for plug connections to an exploring lamp for use in locating trouble, filling gasoline tank, etc.

The generators are made in two sizes; the smaller size has a capacity of 7 1-2 amperes continuously at 6 volts. The larger machine has a continuous capacity of 12 1-2 amperes at 6 volts.

The shaft is particularly heavy and rigid; the laminations of high-grade sheet steel are keyed to the shaft and the windings are imbedded in slots in the core.

The generator is made of sufficient capacity to carry its rated current without overheating and without the necessity of drawing in air and dust from the outside in order to keep it cool. It is geared or connected directly to the engine shaft or an intermediate shaft without any clutches, brakes or speed controlling devices.

An enclosed junction box is supplied with each equipment. This box is of sheet metal, with a removable cover, and contains a small insulated panel board, with provision for the necessary fuses for each circuit and connections for all wires.

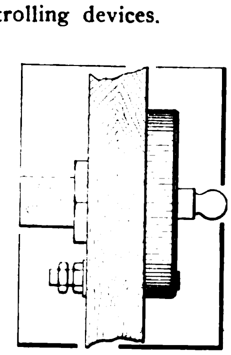

Fig. 4—Profile view of the P. & B. lamp controller

An 80 ampere-hour battery is used with the small size and a 100 ampere-hour battery with the large size, and on account of the fact that it is impossible to over-charge a battery with this system any first-class storage battery can be used.

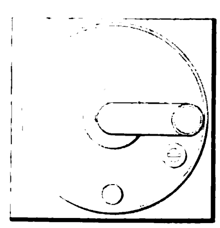

Fig. 5—Front view of controller for gas and spark

Automatic Light-Lighting System

IF evolution may be measured by the increasing speed of transportation facilities, this is only another way for saying that it may be measured by the general increasing tendency to automaticity. As technical developments progress, more and more work is taken off the hands of the operator of a device which is made to serve itself, in a way, thus producing in the mind of the operator a true picture of the agreeable situation termed simplicity. Automatic carburetion, lubrication and illumination are equally important steps in the developments of the modern automobile, the last named having taken no less labor in developing it than the other two.

Among up-to-date lighting systems acetylene is used widely for reason of its white light, which comes very near in intensity to the light of the sun. Its brilliancy is hardly approached by any other sort of artificial light, but this advantage has hitherto been coupled with the uncomfortable obligation of lighting the gas by means of a match, and with the further disadvantage of the driver being forced to regulate the outflowing stream of acetylene leaving the gas tank, since in course of time, as the gas is being used up, the initial pressure in the tank falls off very noticeably. The work of adjusting the nut of the tank, while it is not a hard one, is considered very uncomfortable by many automobilists, and it is just this class of motorists, whose number, by the way, is legion, that are ready to install on their cars a new system, doing away with the acts above described, especially if the price of the lighting system is not too high.

An automatic acetylene lighting system designed for the army of progressive automobilists is illustrated in Fig. 3, which shows the manner of laying out the connections for the gas as well as the low-tension current, leading from their respective sources to a controller on the dash and thence to the headlights. The system here shown consists of three special devices combined to advantage, which are the pressure regulator and the controller, in addition to which there is a special construction of igniter which is located in the headlight. The automatic pressure regulator is of the nature of an automatically adjusting valve through which the gas passes; and it is a feature of the regulator, which is seen in Fig. 2, that while the gas pressure in the tank may be up to 225 pounds per square inch, the acetylene after it has passed through the regulating device has a pressure of but 2 ounces per square inch, which is equal to the weight of a water column 3 inches in height.

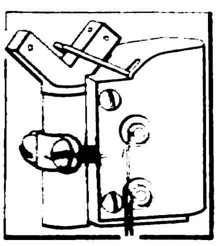

Fig. 6—Igniter incorporated in P. B. system

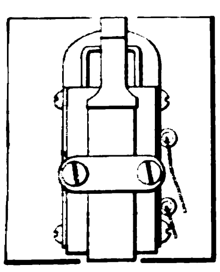

Fig. 7—Profile view of the acetylene igniter

In Figs. 4 and 5 is seen the lamp controller, both in full-face and in side view. The small key seen in the illustration indicates the only way by which the entire system is operated, in that it both serves to close the current, which enables the spark coil to produce a spark at the igniter in the lamp, and at the same time raises or lowers the gas flames by a regulating valve interposed in the gas lead at this place.

The igniter is of unique construction and securely fastened to the acetylene burner as shown in Figs. 6 and 7. The two wires leading from the battery and coil to this point of the system are connected to the two screws seen in the cut, and connection is made through the interior of the igniter to the two points forming a spark gap right above the center of the double burner. This arrangement is a guarantee that when the key on the dash is so turned as to permit the gas to flow to the burner, the current from the spark coil is closed at the same time, and a spark made to appear in the gap of the igniter wires, thu insuring positive and prompt ignition of the gas admitted from the tank to the headlights.

Fig. 8—Sanitary goggles are of little weight

The system is named Motor-Light Lighter, and is the product of the P. & B. Manufacturing Company, being made at the plant of that concern, which is situated at 376 Birnie Avenue, at Springfield, Mass.

Light and Sanitary Goggles

AMONG the drawbacks of touring, assuming the roads to be fair, there is none greater than the disagreeable sensation of a strong air current striking the eyes of driver and passenger, and while it is sometimes not a desirable course to shut out all the air by means of an erect windshield the eyes of the occupants should always be efficiently protected. Fig. 8 shows the latest accessory constructed to serve this purpose, viz., the sanitary goggle, which is made of one piece of transparent and colorless material that does not obstruct the work of the eyes in any way, while the lining is of a soft and strong fabric. The whole thing is comfortable and simple, and protects the nose as much as the eyes; furthermore, the price of the goggle is low owing to its simple construction. The Sanitary Sales Company, of Bradford, Pa., produce this novel device.

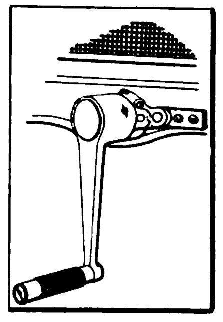

Fig. 9—Safety crank which is back-kick proof

Auto Safety Crank

ACCIDENTS owing to a back-firing motor are met with, at times, even by skilled drivers, and when the trouble and pain of a broken arm are vividly pictured in the mind, there will be hardly an automobilist to deny that an insurance against mishaps of this kind will be worth some expenditure, just as the majority of car owners do not hesitate a long time to take out a policy protecting them from loss in case of the car being damaged by fire. The illustration of the Auto Safety Crank which is offered herewith, represents the latest achievement along the line of back-kick insurance, and being of substantial construction and high-class material, it is sure to live as long as the automobile it is installed upon. The wax engraving shows the manner in which the device is attached to the front cross bar of the chassis frame, indicating the strength of the apparatus. This crank is made and sold by B. F. Perkins & Son, Inc., Holyoke, Mass.

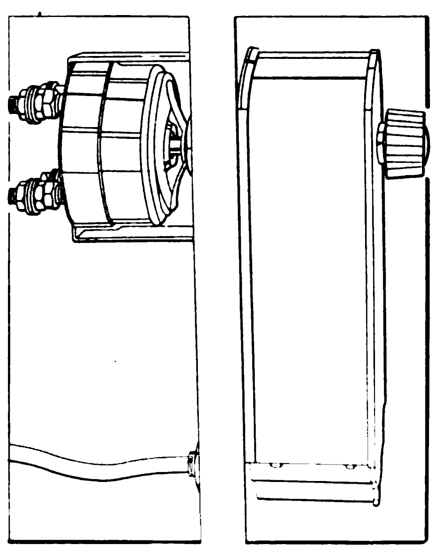

Fig. 10—Side view of Esterline automatic controller, with portion of dash cut away to show rear connected switch

Seen in the Show Window

MATERIAL and workmanship of a high class together with up-to-date equipment are conditions which make the manufacture of strong and efficient bearings possible. The attention which engineers have paid to their constructions for not a few years, therefore, has not been exaggerated by any means, but the result of their endeavor has shown that the efforts made in this field duly paid for themselves. A good bearing, if it is well lubricated, outlives millions of revolutions of a shaft under heavy load. An illustration of a standard product is herewith afforded (AW), this being the Bower roller bearing, made by the Bower Roller Bearing Company, of Detroit, Mich.

EXCESSIVELY high temperature is hard on any man's system, but never does heat make itself more felt than when there are no cold drinks to counteract it. For the Summer time the Hawkeye refrigerator basket will be found useful for transporting food and water fresh and cool for a day. This enables the use of many dishes which otherwise would have to be done without. The basket shown at (AX) is made of strong, tough rattan, woven and bound to stand hard use. It is lined with nickel, which makes it sanitary and rustproof. An asbestos layer is placed between metal and fiber walls, insuring good thermal insulation, and very little ice is required to kept the temperature down. The Burlington Basket Company, 44 Main street, Burlington, Ia., is the maker.

AIR pressure in tires is an important factor in the cost of their use, and authorities hold that every driver ought to be equipped with an instrument for measuring tire pressure, since gauging the same by kicking the outer casing and then judging from the resistance is a method not even deserving the title of "rule-of-thumb." The Brown indicator (AY) is permanently screwed on to the tire valve, thus showing the pressure within at all times, and to inflate the tube the gauge is not removed, but the pump is connected up to the valve of the indicator. Comfort will surely be found in this arrangement, and in addition to the clear readings it gives the gauge is so made and installed that it is not harmed by the revolutions of the wheel. It is the product of the Brown Company, 1091 South Clinton street, Syracuse, N. Y.

THERE are several methods of repairing damaged tires by means of vulcanizers, and these differ mainly in the nature of the fuel, some using alcohol to produce the necessary heat and others electricity, while with a third type, applying steam for the purpose, it is claimed that overheating and consequent injury of the tire are positively avoided. As an example of this latter type the National steam vulcanizer is here illustrated (AZ), in which the water is heated in a miniature boiler by means of a small burner placed underneath it. In its shape this vulcanizer is rather conventional and, as the illustration shows, it is easily and securely attached to the tire. It is made and sold by the National Motor Supply Company, 1919 Euclid avenue, Cleveland, Ohio.

AY—Brown Pressure Indicator stays on tire for good

AZ—National steam type of vulcanizer may be securely attached

BA—Red Cross signal to be placed on physician's radiator filler cap

BB—Ajax revolvable door trunk for transporting reserve tires

UNWRITTEN laws will always command some consideration for the physician violating speed ordinances while on business bent, unless he seriously interfere with life or property of others in the pursuit of his duties. Nevertheless, a doctor who drives his own car will grant that he would preferably save his nervous energy for other purposes than to keep an anxious lookout for pedestrians on his way to a patient, when his mind is generally occupied with important matters. Therefore, a sign clearing the way for his car will be a good thing for a physician to place on his car in a conspicuous position; and this want is being filled by the Red Cross Radiator Ornament, placed on the market by the Motor Car Equipment Company, of 55 Warren street, New York. The cross, which is shown at (BA) is 3 inches high and 2 1-2 inches wide, finished in ormolu gold with either red or green enameled sides. The ornament will be recognized by everybody and very effectively secure the right of way.

RESERVE tires are frequently carried along by tourists, and it may be seen from the manner in which these tires are stored whether their owners belong to the class of careful automobilists or not. These powerful and yet sensitive shoes of the automobile, while they are able to withstand a great deal of strain if kept in good shape, will deteriorate most rapidly if exposed to moisture and sunlight for some time. The value of an efficient trunk for reserve tires is not to be underestimated, and among the several classes of casings the revolving door type is quite popular. An example of this kind of tire trunk is here shown (BB), the door of which revolves in a continuous steel channel, making the trunk perfectly rigid. This trunk is make by the Ajax Trunk & Sample Case Company, 91 Mercer street, New York, and may be fitted with an "Ajax Arch," for the transport of demountable rims.

VOL. XXV. NEW YORK—THURSDAY, JULY 27, 1911—CHICAGO No. 4

THE AUTOMOBILE

Old Dobbin as a Road Destroyer

Horse Is Harder on Highway than Car

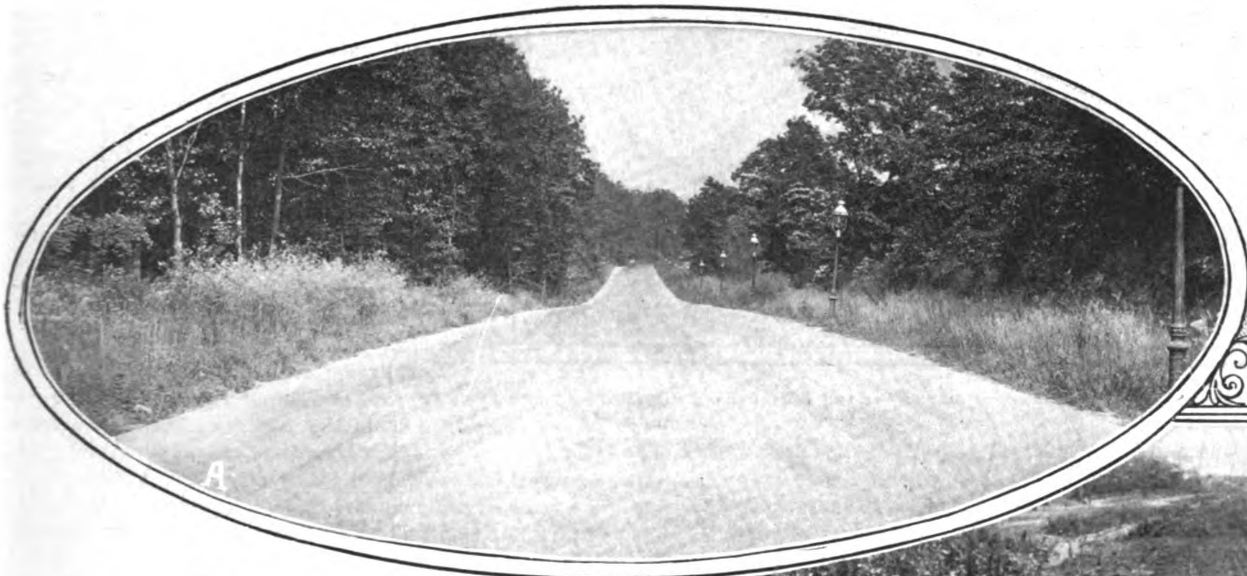

Fig. A.—Showing a dustless stretch of cement block roadway in the Bronx Park
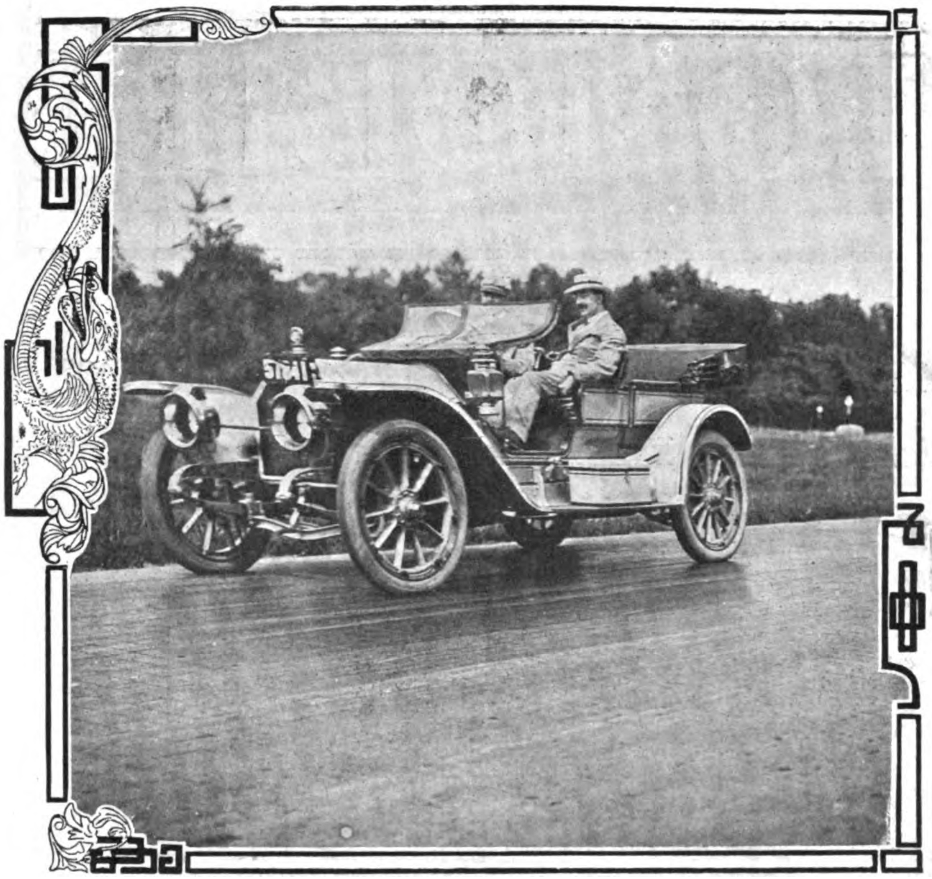
Fig. B.—Efforts are being made to cover up old, worn-out roads with oil and tar, and after a short space of time the surface is similar to this

Critical examination of roads used for horse-drawn travel and automobile traffic discloses the fact that the calks with which horseshoes are equipped do a vaster amount more damage to the road surface than do the wheels of automobiles. Aside from the fact that horses are unsanitary and uneconomic the recent hot wave demonstrated that they are unable to answer the demands of ordinary city service.

OLD DOBBIN and not the automobile is the chief sinner against good roads, despite prejudiced statements to the contrary. In fact the automobile operated at a legal rate of speed has a tendency to improve soft roads by packing them down and smoothing out minor inequalities, while Dobbin's sharp iron calks tear up the surface and necessitate repairs.

On the ordinary country road, no matter how well-oiled it may be, the chopping action of horses' calks will soon reduce it to its primitive condition, while the passage of motor traffic will benefit it under moderate conditions. It stands to reason that the wide, smooth tires of an automobile will act as a sort of power-roller and the picking of the horseshoes will tend to destroy the surface.

Where the roads are macadamized, paved with bitulithic, block or any other surfacing than stone blocks, the action of horses' hoofs is destructive while the rolling of automobiles is not. Where a horse, trotting along at the rate of ten miles an hour has calks on his shoes say 5-8 of an inch long, he picks up soft road surface with every stride and does more



C—Showing a powerful touring car traveling over the cement brick surface at a fair speed without the slightest sign of dust

To illustrate the difference between the action of the horse and the car, take for instance a man with a roller and one equipped with a pick. Let each set out to damage a road as much as possible, the one with the roller, using it as vigorously as his muscles will let him and the one with the pick making three holes a minute. At the end of a day covering eight hours of labor, the man with the pick will have destroyed a stretch of roadway ten feet wide and about 200 feet long, while the fellow with the roller will have improved his road materially wherever he worked.

The most usual argument in favor of the horse is that he is indispensable and that as a consequence, his damage to roads, menace to public health, general uneconomic status and his obstruction to progress must be suffered.

It is true that the common fly depends in large measure upon the horse for the means and medium of incubation and it is equally true that the fly is a distinct menace to health entirely aside from being an unmitigated nuisance. The fly carries germs of disease that are transmissible to human beings and even without the addition of filthy germs, his presence in a bedroom, workroom or dining room is as incongruous and disagreeable as is the presence in the crowded subway car of a man who has eaten onions and limburger for breakfast washed down with alcoholic potations.

The fly causes a vast amount of nervous prostration by his presence in the home and fills sickrooms, hospitals and graves.

If the horse could be eliminated altogether the fly would receive a staggering blow, and his total destruction would be rendered only a comparatively simple matter. Another unsanitary feature of the horse is the fact that where he cannot injure such pavements as granite blocks, he can and does cause the groundwork for fetid, disease-breeding dust. The average city block where horse traffic is general is covered daily with a layer of poisonous material. This necessitates constant labor of street cleaners, and in the event of any laxity on their part in the performance of their duties, a hot sun on the following day will create a condition.

Then, too, the horse is wasteful of energy and is inefficient according to modern ideas. Years ago when transportation was still in its swaddling clothes the horse had a mission. For dozens of centuries he represented the idea of speed. But today his mission, especially in large cities, is finished. He has served his purpose and whether we will or not, he must step back.

He cannot compete as the motive power of trucks or hacks or even delivery wagons with the power of the gasoline or the electric motor. He is too slow and costly. If any concrete demonstration of the unfitness of the horse to cope with the terrible stresses of modern life was needed to show that his day is past, the recent terriffic heat in New York and practically every large city in the eastern half of the country expressed the condition with exceeding clearness.

It has been learned that during the two weeks through which the country suffered such tortures from the heat recently, seventeen per cent. of all the horses engaged in trucking and delivery work died. That means that one out of every six horses so engaged on July 1, 1911, was dead by July 12.

Every city government in the United States east of the Rocky Mountains was so prostrated by the item of dead horses

harm to a straight country road than a racing automobile. Upon an improved road, the damage he does is almost calamitous. His shoes pierce the surface, which is supposed to be waterproof, and break it down so that water can soak through to the foundation. Then when it freezes the water under the surface expands and completes the work of destruction.

The force of freezing water is so powerful that it will burst metal and where it finds a resting place against a heavy body of concrete, for instance, its bursting power is exerted upward and results in a surface humped up and disintegrated in spots.

During periods of warm weather in winter the passage of a horse or an automobile discovers faults in a fine new pavement built the preceding autumn, and in certain districts these faults are laid unreservedly at the door of the automobile.

As this country will spend something over $1,000,000 a day for road construction during the next year and as the most destructive agent in nullifying this work and making valueless this vast expenditure is the horse, it is important to place the responsibility where it belongs.

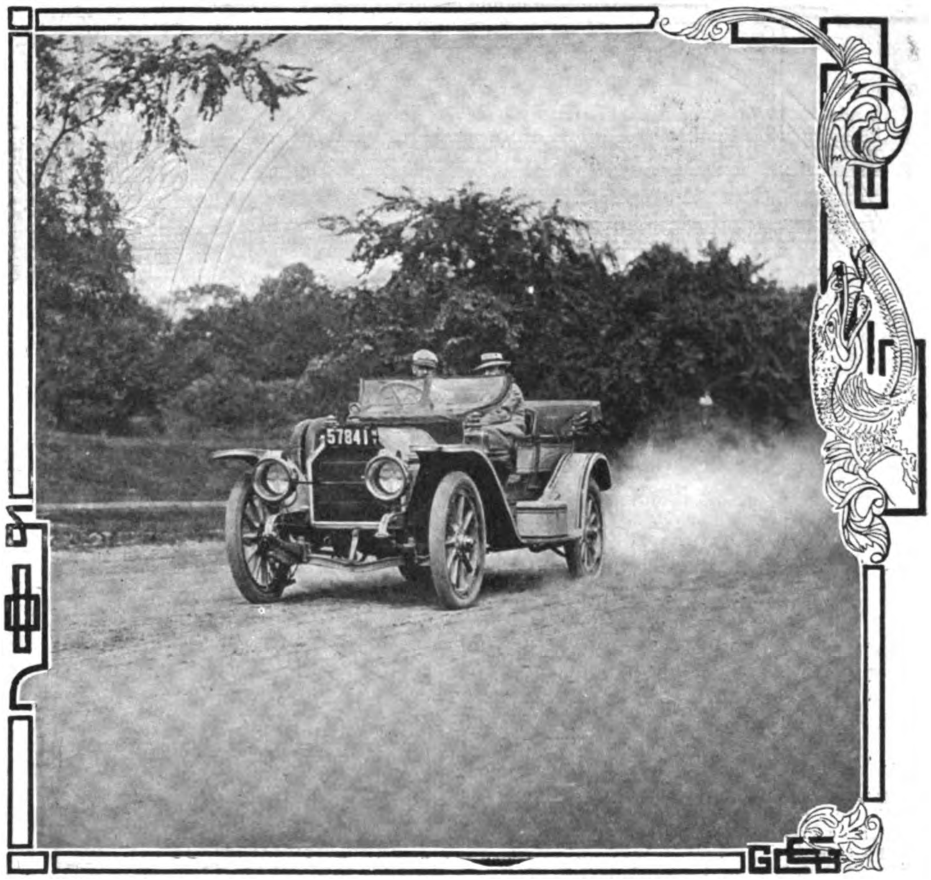
Automobiles have come to stay. They represent a condition of progress in the essential of quick transportation. The volume of automobile traffic is going to increase with every year, because the condition of civilization insists that it shall. The automobile is the advance guard of transportation. It has added billions to real estate values; it has made life on the farm more tolerable and increased its holding power upon the young people. It has made for health, pleasure and recreation and now is striding forward as one of the most important factors in business life of whatever character.

It is not going back because it represents progress, and the wheels of advancement as symbolized in the automobile are rolling inexorably forward. The history of the world holds no instance of retrogression in the art of transportation, and it is not reasonable to suppose that any precedent will be set with regard to such a proven blessing as the automobile.

in the streets that it had to slight other municipal work to pick up the rotting remains. In New York City horses lay dead in some of the outlying districts for a day or more in the blistering heat.

There was an ice famine to make matters worse and to no small degree the suffering of the city may be properly laid to the inefficiency of the horse. Dobbin could not deliver the usual load of ice at all. He could not begin to give satisfactory service and the sight of the suffering horses panting and straining under the fearful heat was a picture to bring tears to the eyes of any person with human feelings. Patiently the poor animals strove to obey the orders of their masters, but they failed and many a ton of ice melted and ran away during that siege of heat owing to the impossible task of drawing it along the fiery pavements.

A comparatively few motor trucks would have saved much suffering to the populace by more complete and vastly more certain and swift deliveries between ice docks and distributing warehouses. The people could have had hundreds of tons of ice that melted on the streets and the horse could have been saved much unnecessary suffering and much useless slaughter.



D—The same car traveling at the same rate of speed as shown in C over a macadamized road. Notice the dust raised

Electricity and steam have displaced the horse as motive power in railway work and that fearful blast of heat this month has gone a long way toward completing the emancipation of the horse from heavy trucking and delivery work in the big cities and placing his duties upon the gasoline and electric motors.

The hog has been barred from municipal life in well-ordered communities and so has the cow. The dog and cat have no reason for existence in crowded cities and both are being legislated out into the country or the crematory. The horse alone is allowed to remain side by side with man on account of his alleged usefulness still being sufficient to mankind to countenance his smells, flies, expense and general lack of sanitation.

The progress in transportation along scientific lines, which has presented to humanity the automobile in its present stage, has also presented the solution to the horse problem. And if any additional force was necessary to make the lesson sink deep into the understanding of thinking men, the hot wave certainly had the force to emphasize the situation.

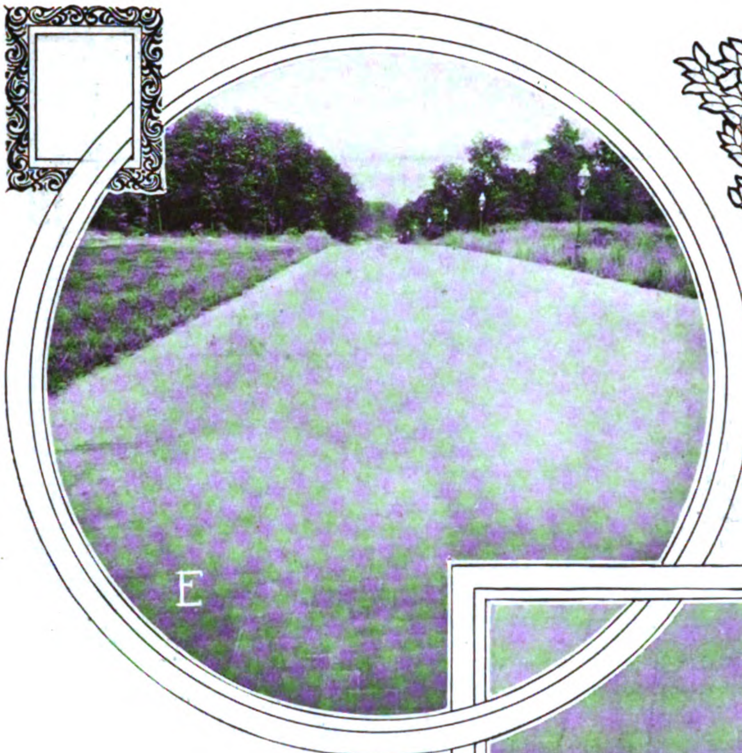
The indictment against the horse is complete in many counts. He is destructive of the roads to a greater gross amount annually in the United States than the sum of the Rivers and Harbors and the Diplomatic appropriations of the United States Government. If half the flies are accountable to horses and if all the flies shorten human life by the span of two years, as the scientists say, the horse is chargeable with shortening the lives of 100,000,000 people, citizens of the United States, by one year each. If the average life is 33 or 34 years in length, it means that 3 per cent. of man's usefulness is paid for the privilege of having horses and flies as incidents of his life.

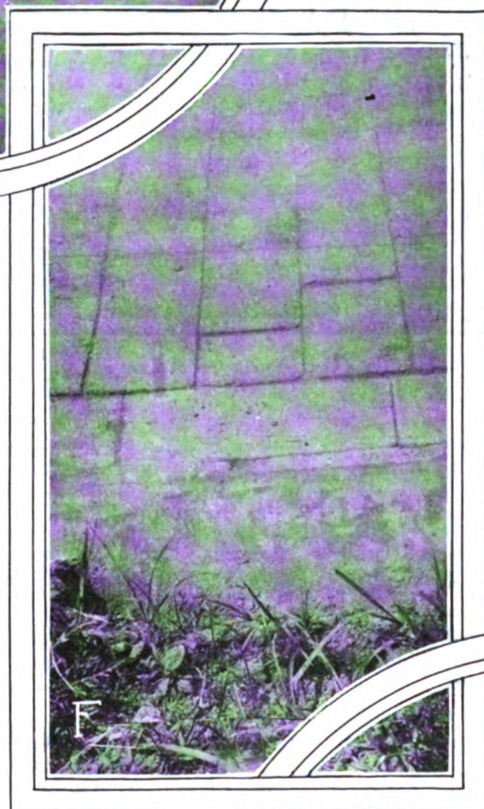
The automobile is faster, surer, more enduring, more economical, more healthful, actually cheaper in operation and first cost and vastly more satisfactory than the horse. In the matter of accidents, those in which horse-drawn vehicles figure are manifold more numerous than those in which automobiles figure. This statement will probably be challenged and to those who question its uncolored truth, reference is made to reports of street casualties of any city in the United States. In crowded sections of New York City the proportion is about ten to one and the proportion of horse-drawn vehicles is nothing like this ratio.

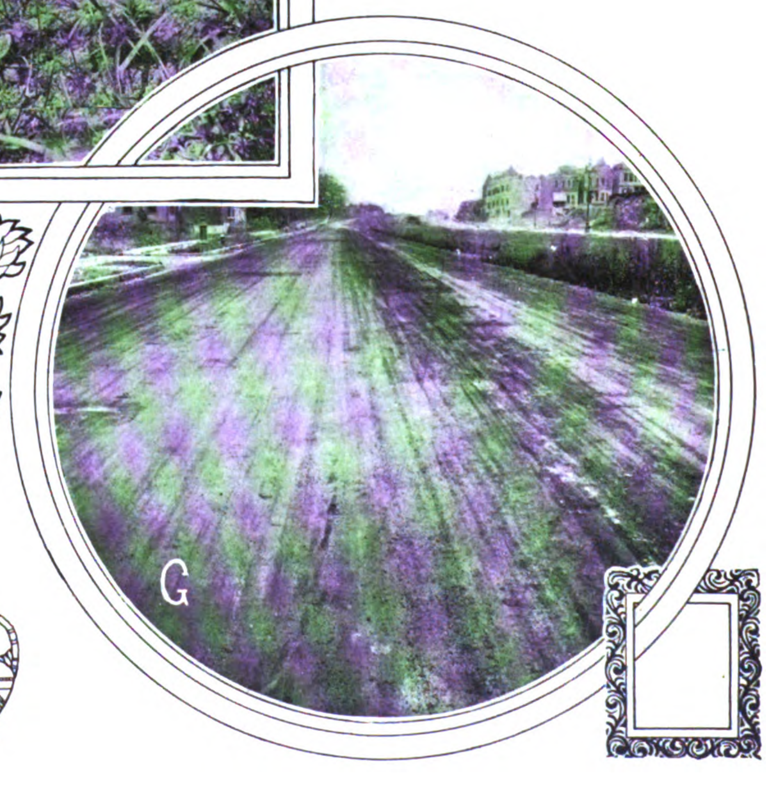
No flies breed in gasoline and lubricating oil drippings and no streets are covered with noisome matter as the result of automobiles standing along the curbs. Suppose that it is admitted for the sake of argument that the horse is better than the automobile in every way but one, it will be found that the single factor is sufficient to counterbalance all the advantage that the supposition gives to the horse. Take them in order of economy, health, speed, certainty, damage to roads and general efficiency and give the horse all but one of the qualities in greater degree than the automobile and the car must triumph. If the horse makes for health, has more speed and certainty and causes less damage to the roads than the car, the automobile would still displace the horse because it is more ecenomical in the cost of operation. If the horse is more economical and all the other things mentioned, except in the matter of health, the growing regard for human comfort and life would still force the supremacy of the car. But when the situation is carefully viewed and each condition weighed with care, it is found that the car possesses all the prime qualities and the horse none of them in comparison with the automobile.

Out in the country where the land lies open to the purifying and life-giving rays of the sun, the horse may still find a moderate field of usefulness. Knee-deep in the odorous bluegrass he may find a mission, albeit but a temporary one. His colts may neigh and toss their manes in the up-land pastures for a few years and the patient mares may browse in the shaded lowlands where the brook smiles and sparkles its way to the great river. But his day in town is ended. His sun has set and, as inexorably as the progress of Juggernaut, he will be forced away from contact with mankind in the cities.

He has been weighed in the balance and found to be lacking in modern efficiency. He has been convicted of breeding dis-







E—General view of the cement block road adjoining the Pelham Parkway, in which the good even surface will be noticed

F—Cement block roadway as seen walking along it, showing the sides made of cement banking with a block interposed between the banking and the edges of the transverse blocks. No provision for expansion is apparent

G—This illustration shows a roadway that has been treated with an oil preparation for laying the dust, and in which the part usually used by horses is badly cut up

ease. He had been demonstrated to lack power and economy compared with other mediums and from the first place in man's affections he has sunk to the point where self-preservation demands that man eliminate him from man's crowded dwelling places, and he is now shown to be destructive of roads and consequently a direct obstacle in the path of progress.

Nobody would keep a pair of worn-out shoes for their former association. Such articles, no matter what has been their usefulness in the past, are not decorative and are of no service. They occupy a place that belongs to something useful or beautiful and the only logical thing to do with them is to consign them to the scrap heap. And there, unqualifiedly as far as the city is concerned, belongs the horse.

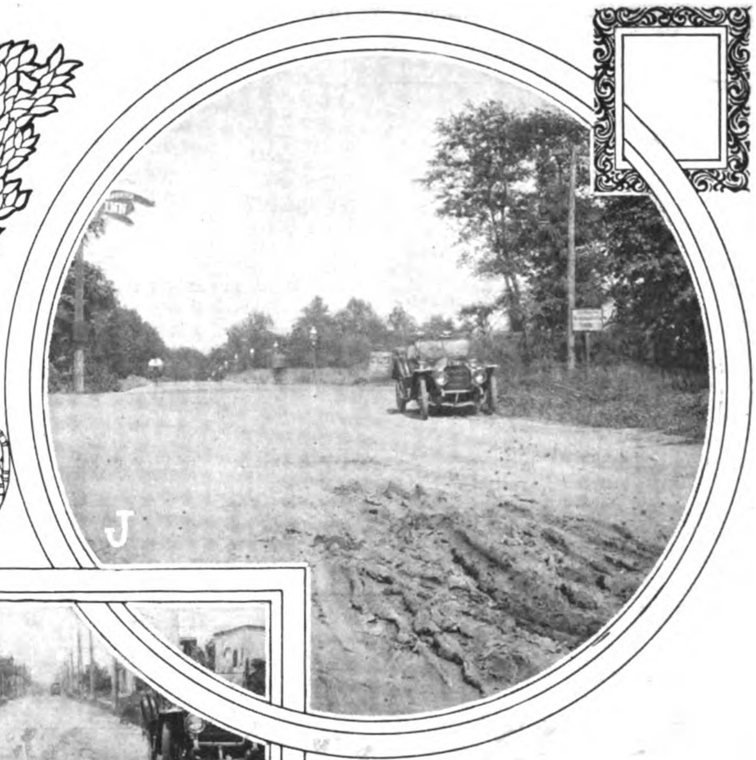
The Scientific Side of Road-Building

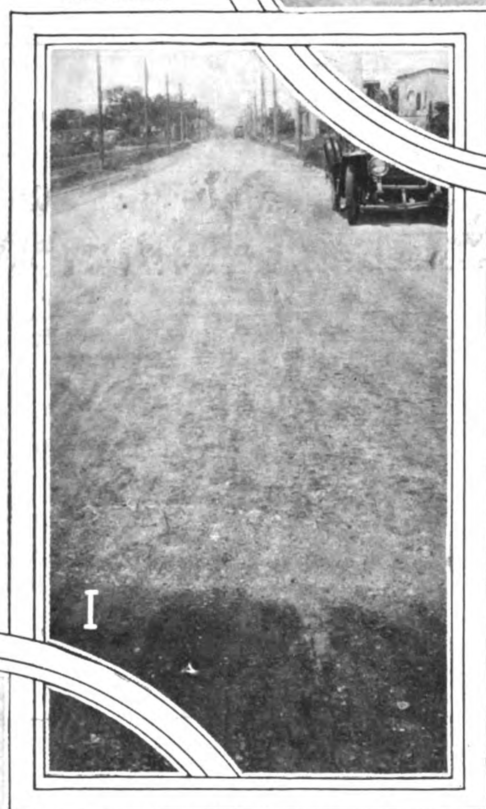
In the making of roads there are two things that must be paramount in the minds of the builders, and they are that the road surface shall be more or less impervious to moisture and that the under bed shall be properly drained. It is not proposed here to deal with road-making in the detail form but rather in the abstract. Until the advent of the automobile the point that had to be borne in mind was the tractive effect of horses, and in this respect the efficiency of the draft horse depends upon his foothold. If that be good he can use his entire strength, but if the road surface is hard and slippery the power that could be used in overcoming the resistance of the load will have to be divided in so far as he will only be able to use the power he possesses until the slipping point is attained. The metal of the horseshoe and the hardness of the road surface are diametrically opposed to the hardness of the road surface and the elasticity of tires. Besides, a hard road will tire a horse out much quicker than a road that offers a certain degree of elasticity, or "give." To carry the matter still further, after the elastic limit is reached, as in the case of soft sand, the hoof sinks in and the tractive effort is reduced.

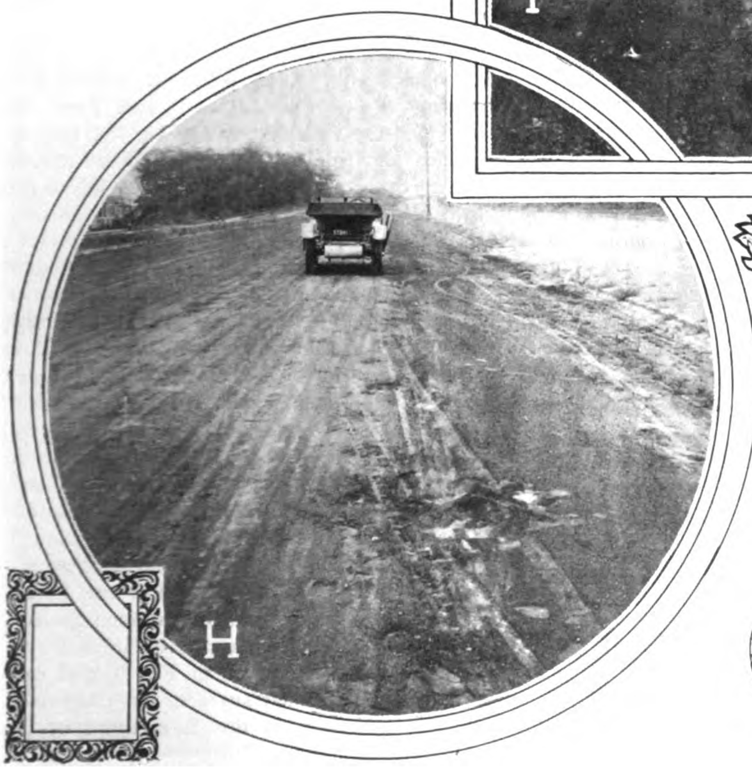
The metamorphosis that has taken place in the last decade has given food for thought to the designers of roads, and with the overwhelming increase of mechanical traction and the use of resilient tires conditions have altered alarmingly, and what previously may have been found to answer will have to be altered to suit present and coming conditions or new ones will have to devised where the old ones are found wanting.

One feature that has been tackled in a somewhat half-hearted manner is the dust nuisance, and it is admitted that in this particular the mountain will have to come to Mahomet rather than that estimable gentleman to the grade. Some cars are less inclined to raise dust than others; nevertheless if the dust is not present one of the greatest drawbacks will be eliminated. The logical method of overcoming dust is to construct roads that are homogeneous as to surface and that can be cleaned either by mechanical means or by the gentle rain from heaven. As an illustration of a road that is dustless and at the same time suitable for the new locomotion, that is shown in Fig. A offers excellent advantages. It is situated in the Bronx Park and has been built by the Park authorities. The road bed is of concrete and the surface is made from cement bricks set in with tar, in a manner similar to that used on the wood block roads. It has been laid now a matter of a little over twelve months and is almost exclusively used by automobile traffic, pleasure and freight alike. Running alongside the Pelham Parkway, it offers a handy means of comparison between the average macadam road and the dustless qualities of the block pavement. Fig. C shows a car traveling over the cement blocks, that have become somewhat shiny with the continual roll of the pneumatic tires and Fig. D represents the same car traveling over the Parkway at precisely the same rate of speed. In the first illustration there is not a particle of dust being raised, whereas in the second picture an impenetrable cloud is left in the wake of the car. Reference to Fig. D clearly shows the camber of the new form of road, and it is evident that after a downpour of rain it will be self-draining as far as the surface is concerned. In dealing with this point one thing that has to be borne in mind is the porosity of the substance of which the road surface is made, and it is conceded by authorities that 2 per cent. is the maximum. This is necessary owing to the liability to disintegrate under the action of frost if the adsorption is greater. A general view of the road under consideration can be obtained by referring to Fig. E. The cleanliness of the surface is in a measure due to the absence of horse-drawn traffic.

The method employed in this instance of finishing off the sides is shown at F. The sides of the road are formed by blocks similar to those used in the running surface, with a







H—Another example of a road surface running parallel to that shown in Fig. G, but with a surface so soft that even a person's footprint makes an impression on the surface. The road shown on the right of the picture is being prepared for a tar surface

I—Part of the White Plains road, showing two types of surface. The light surface is concrete with a cement wash covering and fairly well cambered, whereas the blacker section shows the existing road covered with a tar material and is torn to pieces on a hot day by the calks of the horses' hoofs

J—This is a strip of roadway between two stretches of cement block roadway and it is proposed to replace it in the near future with the cement blocks

K—View taken recently of the existing Boston Post Road about a mile after it leaves the White Plains Road and about to be widened

side banking of cement tapering up to the road surface in the form of a triangle, in the manner illustrated. As was shown recently in THE AUTOMOBILE, in making roads of bricks and concrete blocks, there is a necessity for an expansion chamber along the sides to take care of the expansion and contraction due to the changes of atmospheric conditions. This seems to have been overlooked in this instance, but as there are no sidewalks and the road is not bounded by a solid substance, such provision may not have been found necessary. In order to show the cement banking some earth had to be scraped away, but in the ordinary course of events the road edge is similar to that shown in Fig. E.

Fig. G represents a road that had been treated with an oil preparation that has two effects. It lays the dust so long as the surface remains unbroken and the action of pneumatic tires thereon is to bind the upper crust firmly together. The center part of the road shows the section usually used by automobiles while on the left and right hand sides it will be remarked that the oil surface has been broken and this is the section over which the horse's hoof comes in contact. Of course after the calks of the hoofs have started the damage it is not long before the infection spreads to other parts of the road. On the right-hand side of this picture will be noticed two other roads running parallel. The one in the center has been oiled and sprinkled with fine sandy siftings and is very soft and entirely unsuitable for automobile travel. An idea of the softness of this road can be gleaned from Fig. H, where it will be seen that even the imprint of the pedestrians' feet cuts the road up and if the foot is drawn along it cuts up the surface.

The road on the right-hand side of this picture shows a road in the course of making or rather fixing up. Belonging to the macadam variety with a stony surface bound together in conventional form it is at present being coated with a tar substance. This will tend to make a dustless surface, but upon examination it was found that the surface was not homogeneous at all and a slight kick sufficed to break the surface and mar the smoothness. It is little use covering such a road with a dustless surface if the foundations are not fit to take it and stand the wear and tear. This brings one to the point that it is so much money thrown away to try and convert otherwise unsuitable roads into good ones by placing a covering over them. It will be found necessary in the near future to remake such roads and the money could be used to better advantage in experimental work rather than in covering miles of roadway with what has been found from experience to be a makeshift.

On the White Plains Road just before it strikes the Boston Post Road and the Pelham Parkway there is a stretch of road that compared with that immediately alongside of it in a very favorable manner. The surface is shown in Fig. I and consists of concrete with a cement-washed surface. In the heat it remains solid, while the road seen in the foreground of the

L—In widening the Boston Post Road boulders are being used to form a roadbed and the illustration depicts the heterogeneous class and size of material being employed. It is proposed to widen the road to the posts seen on the right-hand side of the picture

picture is one with a tarred surface and the horses' hoofs tear it up and render it useless. The average road surface that has received little treatment at the hands of the engineers is shown in Fig. J. No amount of fixing will ever bring such a road up to modern requirements until the foundations have been reached and built up anew.

Talking about foundations brings one to what are the best forms of foundation that have given satisfaction in the past. It has been found that foundations should be made of material of approximately the same size and this condition is obtained by crushing the stones that form the bed and passing them through suitably contrived apparatus so that they will pass the four-inch hole, grading to a smaller size the nearer the surface they are required.

Fig. K represents part of the Boston Post Road now in the contractor's hands to be widened and partly rebuilt. The position of the car in the illustration shows how far it is possible to go at the present moment. The road is being considerably widened at the present moment at this point, and it is interesting to see how this is being done. Instead of using the method above described boulders of all sorts and sizes are being dumped in the manner shown in Fig. L and the posts on the right hand side of the picture show the increase in width to which the new road will extend. The saving in labor in the method being employed is, to say the least of it, enormous, and instead of striving to improve the roads such crude methods as these seem futile.

No matter what material is employed for the road surface there is one vital point that must be borne in mind, and that is that the crust must be so made that it will remain intact or when signs of wear become apparent such repairs must be made in order to reinstate it. The reason for this is obvious. If the upper crust is made waterproof the rain will run off and suitable means must be used to carry this water away in the nature of ground drainage. If this is not the case the substrata will be loosened and cause the road to cave in in parts. The greatest damage inflicted on roads is undoubtedly that caused by the calks of horses' hoofs, as in the endeavor to perform their allotted work it is necessary that these calks should dig into the surface so that the horses can obtain a foothold. The fore feet are usually fitted with shoes with one calk or a toe weight to lengthen the stride, while the hind feet are invariably fitted with three calks. These calks will in time penetrate the surface and the next downpour will materially assist in enlarging the hole.

The Trend of Events—

Points to the building of good roads, remembering that they should be maintained as well as constructed—the old way has to do with the expending of money in the building of roads, and the high disregard of the maintenance of them.

Tinkering on the Road

There is not a lot to be learned in order that the novice can successfully drive his recent purchase even on an extended tour, provided nothing in a mechanical way happens to upset his calculations. Some things happen that have to be attended to on the spot in order to get along at all, but it is the part of wisdom to leave experiments at the commencement to such time as when the car is in a garage instead of the open road miles from anywhere.

WHEN the novice takes over a new car and starts out for a day's enjoyment his pleasure may be marred by a persistency on the part of one of the spark plugs to foul up. Or at any rate, if it is not the spark plug something, perhaps, is amiss with part of the electrical equipment that is like so much Greek to him. There is a danger in tampering with several parts in the effort to locate the trouble, as the manner in which most novices locate trouble is to take the kit out and choose a tool indiscriminately, turning everything there is to be turned, with a fair chance of finding himself stranded. The road is not the best place to fiddle with the electrical equipment of the car without a previous and thorough understanding, as it takes very little on the part of the operator to render the entire system non-productive of a spark at all the plugs. This being the state of affairs, and supposing that one of the cylinders does not fire, it is most disconcerting to continue to drive with the motor in this condition and damage may result therefrom.

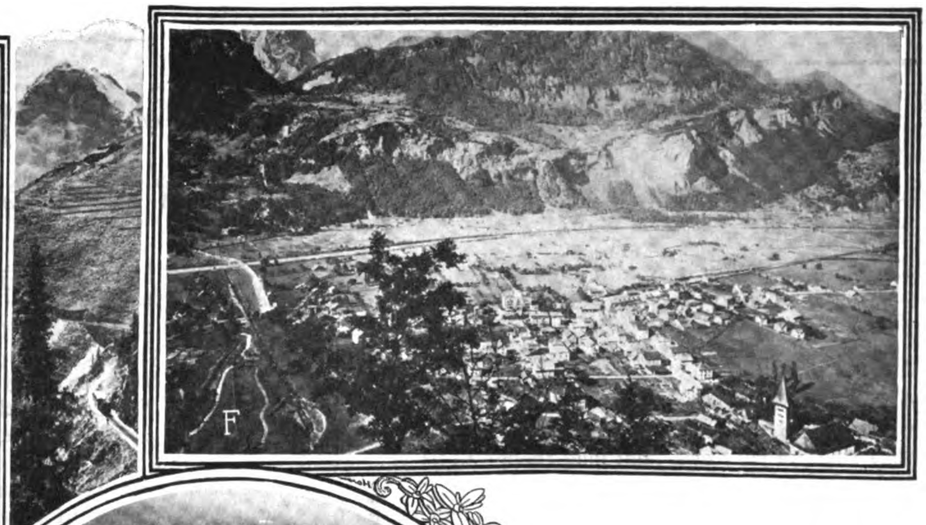
In order to postpone the locating of the trouble, if the ordinary tests have been applied, it would be better under the circumstances to remove the spark plug and drive the car at a moderate rate of speed either to the nearest garage or home, being careful not to run in the wake of another car and sucking up a peck of his dust.

WARNING GENERALLY GIVEN IN ADVANCE.—Just before the motor seizes, a pinging sound will be heard. When this warning is given, stop the motor at once and examine it carefully, or serious damage may result from a dried-up water system.

Before the close of next October it will be possible for the touring automobilist to reach the Riviera, via Switzerland, over a 452-mile route, using his car all the way. Even now the road, although several links are not yet completed, is in constant use, the travelers shipping their cars over the uncompleted portions of the route in specially constructed goods wagons attached to electric trains.

THE longest and most pretentious public automobile passenger route in the world, namely, that of 452 1-2 miles, from Evian-les-Bains on the Southern shore of Lake Geneva, Switzerland, to Nice, "Queen of the Riviera," on the Mediterranean Sea, was opened for traffic with appropriate official ceremony on the first day of July. The entire trip over this romantic highway is made by passenger automobiles, with the exception of two or three very short links over the Alpine Road, where electric train service is being used temporarily. Across these spans of metal the motor cars are conveyed in especially constructed goods-wagons to the points of the completed automobile roads, where they are unloaded and put into commission again, taking up the thread of the journey. By October of the present year the portions of the route which are now served by electric train will have been completed, thus making a continuous automobile highway from frost-laden mountain and lake to sunny azure sea. The journey occupies five days, and affords a constant succession of delightful views.

Beginning with "Evian the peerless," the first day's trip takes in the walls of the ancient Château de Ripaille, the Dranse Valley, the Devil's Gorge, the Col des Gats, the entrancing Giffre and Arve Valleys, the gorgeous panorama of Callanches, the very shadow of Mt. Blanc, and the tranquillity of Chamonix. The second day includes the picturesque Col des Arvis, the Annecy and Bourget lakes, the Arley Gorges, the Little St. Bernard and the Vanoise, and through Aix-les-Bains to Chambery. The sun of the third day lights up the Calibier Col, the Lantaret, the majestic Meije, the Barre des Ecrins, a multitude of summits of the Pelvoux and fertile spots of the Guisane Valley, at whose



D—A view of the Alps from Mürren, the highest inhabited village in Europe

E—Sheer up from the sea along the Mediterranean rises a crest of hills protecting the seashore towns

F—Typical valley and mountain scene that is met in many parts of Switzerland

the Riviera Automobile Road

extremity Briançon lies. The fourth day from Briançon to Barcelonnette, the road winds through the surprising Col d' Izard, the Col des Vars, the Queyras Valley and the awe-creating Mount Viso.

Leaving Barcelonnette early on the morning of the fifth day, automobile passengers find themselves admiring the Col d'Allos, the Colle St. Michael, the Verdon and the Var Valleys, Mescla Gorges and the alluring Côte d'Azur. Finally the satiated travelers alight, to find themselves as the day closes at their journey's end, with queenly Nice and her riot of carnival gayety spread before their eyes.

This high altitude highway opens up a surprising panorama to the tourist who has become weary of train travel or pedestrianism and seeks new glimpses of scenes which may be classed as akin to the sights of fairyland. The tariff per passenger is $38.70, not including hotel accommodations and meals en route, which may be figured at about $4 per day.

To tourists familiar with the Alpine summits and their relative valleys, this new highway is regarded as being unique, straggling away, as it does, in its serpentine course along the brinks of stupendous precipices, as well as penetrating the wilds of hazardous gorges.

Scintillating glaciers, dense patches of dark green woods, wide stretches of snow-clad plats, verdant fields, mighty mountains, streams leaping from boulders into seemingly bottomless caverns, roaring cataracts, mediæval towns, villages crowned with castles, limpid lakes and, finally, a dash into the semi-tropical zone, dotted with luxuriant gardens. These are some of the advantages enjoyed by the automobilist.

Perhaps as interesting a feature as any other in connection with this tour is the special goods-wagon for the transport of automobiles. The wagon is enclosed, affording the motor car a safe journey.

The owner of the motor car on a private tour may safely ship his machine from Paris to Evian and proceed to Nice, certain that his car is in reliable hands while connections are being made over the temporary electric lines. Likewise, this transportation is extended for the convenience of the automobiles making the daily tour over the romantic Alpine Road.

Kerosene for Automobiles

When it is fully realized that the only objection to using the cheaper and less volatile distillates of crude oil lies in the difficulty of their carburetion, it becomes evident that the chief line of improvement of the carbureter lies in their ability to be adapted to these fuels.

CARBON trouble must be charged in great degree to inferior carburetion, and that this source of trouble is becoming more acute every day is recognized, due to the fact that the non-volatile constituent in the gasoline supply is being increased from time to time at the cost of the more volatile hexane which is being decreased in the same ratio.

Fully 50 per cent. of all the volatile portion of crude oil belongs in the distillates approaching decane, and it can therefore be readily appreciated that the distillers of oil are extremely anxious to have decane liberally represented in automobile gasoline. It is not believed that they consult the builders of carbureters in matters of this sort, nor is there any record of their having called a convention of autoists with a view to being favored with its opinion as to the efficacy of kerosene oil for use in automobiles.

Surprising as it may seem, the inventors of kerosene motors have been put out of business due to the improvements wrought in carbureters and the splendid backing of the distillers of crude oil. Just as fast as carbureters are improved so that they are rendered more capable, the distillers of crude oil add another dash of the less volatile constituents until finally the carburetion problem has arrived at a near approach to the time when automobile gasoline may contain 50 per cent. of kerosene oil.

Since this is the exact amount of kerosene oil present in the whole content, there is no inclination on the part of the distillers of oil to add more—in fact, it would even be a detriment to do so.

THERE is a strip of coast-road along the Gulf of Salerno, in Italy, between Salerno and Sorrento which is not excelled anywhere in the world for perfection.

When Judgment Whispers Don't

(Aphorisms Apropos of the Automobile)

There are so many acts that may be committed with impunity if they are done at the proper time that the thought is suggested that reflection should accompany every undertaking.

DON'T adorn the fleeting moments with idleness.

DON'T work overtime on an undertaking that promises failure.

DON'T stand in your own light long enough to let your neighbors unhorse you.

DON'T stand in the light of the man who has no purpose but to treat you fairly.

DON'T exact "the ounce of flesh" if the surgical operation so represented is likely to defeat the project.

DON'T become too much attached to "distant verdure" even if it does look the greenest.

DON'T be persuaded to think that an impracticable idea will work just because some other fellow says it will.

DON'T finance any impossibility at the suggestion of the beneficiary under the plan.

DON'T derange the plans of the fellow who promises too much—let him alone.

DON'T invite mere schemers to join you in your everyday enterprises.

DON'T strike the blow that will kill the goose that lays the golden egg.

DON'T listen to the North wind while the South wind robs you of your enchantments.

DON'T scatter aimlessly the thought which, when properly managed, will count on the side of equity.

DON'T incorporate into a mechanism the disorders of a severe climate.

DON'T build an automobile so poorly that you will have to try it upon the dog.

DON'T burn the midnight oil assiduously for no better purpose than to purchase a necklace for despair.

DON'T go to a body-making plant for a good automobile—they are fashioned in machine shops.

DON'T put a poor-looking body upon a well-made chassis—it is like hiding your light under a bushel.

DON'T neglect business for the purpose of purchasing an inferior make of automobile—you will suffer a double loss in the interim.

DON'T place your crest on the panel of an inferior product—you might be taken at your own estimate.

DON'T try to turn the course of logic and of truth—these streams flow in a bed that was fashioned by the hands of time.

DON'T join the squadron of the discontented—act with wisdom and your path will lie in the opposite direction.

DON'T help to fill the storehouse of poor ideas, or lend financial support to projects that have no stamina.

DON'T pay the price of an uncanny idea offered you by a canny man.

DON'T forget that curses, like chickens, come home to roost—uncalled-for abuse of the repairman may result in a "brood."

DON'T order a green color for the body of your automobile if you reflect the same color in your actions. The two shades may not match.

DON'T rely upon a superficial examination of a car that is to cost you coin of the realm.

DON'T be afraid to talk up in meeting—the agent, perhaps, is a trifle deaf.

DON'T misjudge the power of action—if you act as if you have a sense of proper discrimination the dealer will take his cue accordingly.

DON'T risk the idea that supreme happiness comes with the possession of a car—delights desert the owner of a poor affair.

DON'T purchase a manicure set in substitution for tools for the tool-kit of your automobile.

DON'T despair if you have to apply surgery to the car of your choice—cutting out some of the bad ideas might have the effect of giving the good ones a better opportunity to perform their proper functions.

DON'T serve as the "evidence" if a fraud is being perpetrated nor play the principal part.

DON'T live in anticipation of delights to come if you give your money to the second-hand man first.

DON'T discourse with the seller at considerable length about what you are to get for your money—let him tell his part of the story in writing.

DON'T waste too much time on a highly accomplished salesman—your need is in the shape of a highly accomplished automobile.

Stopping the Car Quickly

Although the careful driver rarely allows himself to be caught in such a position that the safety of the car and its occupants depends on the ability of the brakes to immediately arrest forward progress, it sometimes happens that a quick stop is highly desirable. The sudden stoppage of "the car ahead" is a case in point.

IT occasionally happens that skidding occurs when the autoist is endeavoring to bring the car to a stop within a limited space. No matter what the condition of the roads, whether wet or dry, it is at times difficult to pull up quickly if another vehicle has suddenly stopped a short distance ahead of the car. Setting the brakes introduces side slip at the rear, and while this tendency can be checked by means of the steering gear the forward skid will continue in many cases. The fault is, of course, on the part of the autoist in having approached the other vehicle at too great a speed consistent with the state of the road and with regard to the efficiency of his brakes. To obtain the maximum retarding effect under such circumstances, the brakes should be applied and released alternately with a quick vibratory motion of the foot, a powerful braking influence being thus brought to bear on the wheels, and the intermittent periods when they are free to roll enabling them to maintain their grip on the road.

Willing to Give Him Another Chance

An Irishman who was sent to clean the windows of the 27th story of a sky-scraper lost his hold, violated the speed limit in falling to the pavement below, and a mob quickly collected, when one spectator said: "Poor Pat is no more!"

Pat (opening his eyes at the sound of voices): "Sure and Oi'm not dead!"

Convenient Cop: "Wait a minute; here comes a big limousine!"

Items from Foreign Lands

Interesting extracts, mainly from the United States Consular Reports, in which the status of the automobile in foreign parts is tersely set forth, and the prospects of extending the American market are called to the attention of those interested.

HONGKONG and Canton are two cities in China which are entirely unfit for motor car traffic, owing to the narrow streets. In some instances the roads are little better than mere footpaths, being from 4 feet to 6 feet wide. Sharp turns abound here and there, while at intervals in the road the automobilist encounters steep flights of stairs. Shanghai offers more encouragement to the motor car driver, the streets being quite wide, a fact which may, in a measure, account for 400 automobiles being found in the city.

The "foreign devil" who invades the Celestial Empire is not justified in feeling too sanguine as to his ability to penetrate into every section in an automobile. He will find himself absolutely barred from certain walled cities. He may drive to the very gates with his motor car, but here he will find himself facing a cluster of very disagreeable obstacles, including the police, mobs of coolies, swarms of "the people" and bands of residents who, with arms raised in the attitude of horror and hostility, threaten the automobilist who dares to make an attempt to pass the gates. Popular prejudice cries out angrily against foreign invasion.

The Swiss are going in for very heavy motor trucks for use in the Tyrolese Alps. These vehicles are built to carry very heavy loads up the steepest mountain grades. To this end the 40-horsepower engine is being utilized. Horse-drawn vehicles have disappeared almost entirely from these mountain highways.

Halifax has just acquired its first motor truck. Its appearance on the street aroused a good deal of interest. It has a capacity for carrying three tons burden. Oil barrels will constitute its loads, for the time being, at least. The truck will run between Fairview and Dartmouth. The body of the truck was built in Halifax. The truck itself was made in this country.

Calgary, British Columbia, has kept pace with the times, in a motoring sense, the latest movement in that far-away section being found in the organization of the Calgary Automobile Club. The membership in the beginning was twenty-one. The fee for joining is $10. The literature of the club sets forth its objects, which include the making of good roads, the erection of signboards, the building of club houses, and legislation against reckless drivers. There are 300 automobiles in the city.

Italy's King is one of the most accomplished as well as enthusiastic automobilists in Europe. Not alone does he possess some of the finest motor cars made, but he can drive a car as handily as the experienced chauffeur. Besides, His Majesty is capable of repairing his own automobile, he being a practical mechanician.

Automobilists riding through Upper Studley, a community near Trowbridge, England, are apt to have their attention called to an unique pile which suggests that it might well be regarded as a monument to the (at least partial) passing of the horse in that vicinity. It is nothing less than a heap of cast-off horseshoes, weighing 150 tons, standing 17 feet high and measuring 10 feet on each side. The value of the iron is at least $2,000. The owner spent two years in collecting the shoes for a curiosity.

Marmon "Thirty-Two" in Detail

Apart from Refinements Will Remain Unchanged

In presenting the latest type of Marmon it will be noted that there has not been any attempt on the part of the designers to make radical changes in design, and it is rather a matter of sticking to adopted lines and tried plans. One size power plant is employed for the several types of body work and the detail parts show accessibility and consideration for the user.

THE plant of the Nordyke & Marmon Co. is located at Indianapolis. By increasing the size of the factory from time to time another industry has been added to its former field of endeavor, the automobile end now being as large as the milling machinery business which forms the other half and which has been established for over half a century.

It is the aim of the builders of the Marmon to make as much as possible of its automobile product in the one factory, and,

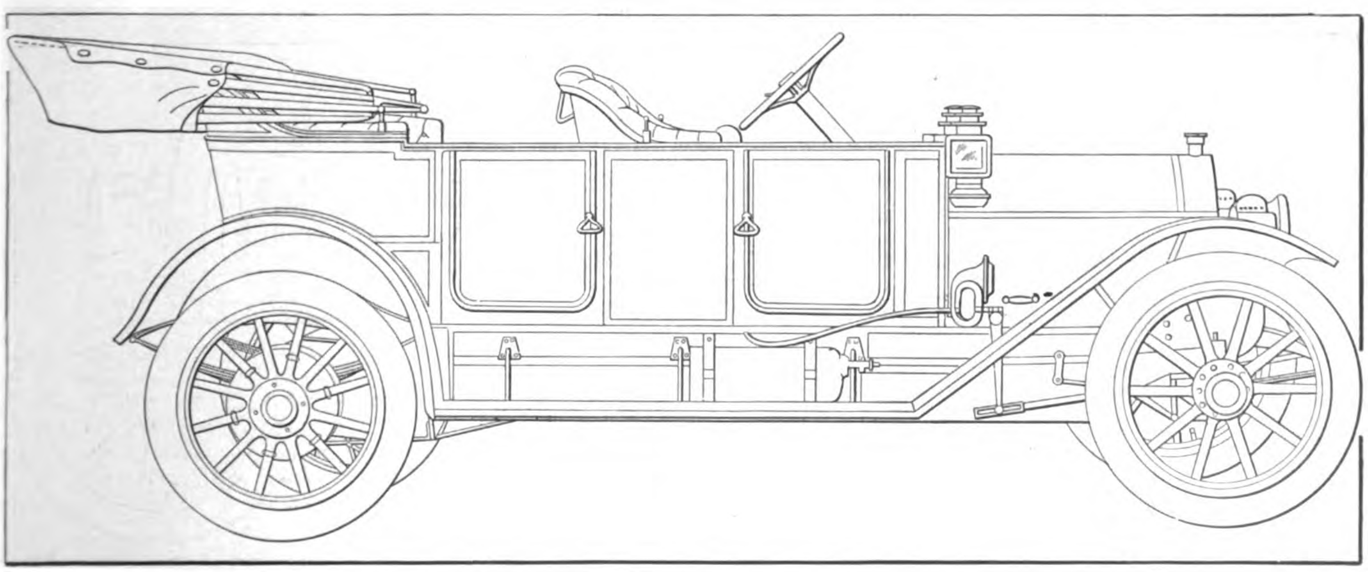


Fig. 1—Marmon "Thirty-two" with five-passenger fore-door touring body of straight-line design

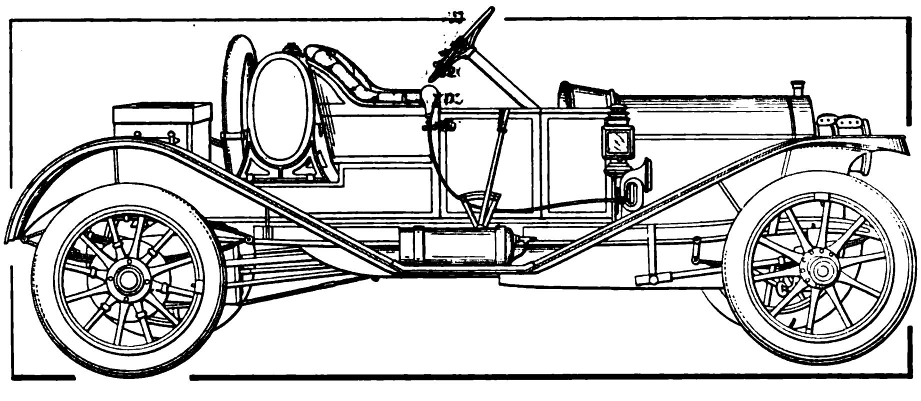

Fig. 2—Showing the Marmon Roadster, with oval gasoline tank and provision for storing the spare tire

with the exception of smaller accessories such as ignition apparatus and the like, the car is built from the ground up under one roof. According to those in authority the yearly model will soon sink into oblivion, and such improvements as may be found necessary or desirable for the betterment of the product or the convenience of the users will be incorporated in the cars as soon as the series allows. It is the intention of the Marmon company to increase the output for the coming season, and the previous year's "Thirty-two" will remain unchanged in most respects.

The comfortable-looking five-passenger touring body, with closed front shown in Fig. 1, indicates that the question of weight has been carefully studied, the passengers on the rear seat being bestowed within the space allowed for the wheel base, and as there is no overhang of the body the riding qualities are thereby enhanced. The mud guards are fitted with inside valances, thus protecting the body and passengers on dusty and muddy roads.

The Roadster model shown in Fig. 2 bespeaks forethought in one vital particular. The spare tire is always a matter that, unless proper provision is made for it in the design of the body, becomes an eyesore, and the method employed in the case in point places it in an accessible position, yet out of the way, so that it is less likely to be damaged by continual handling and the action of the elements. The gasoline tank, placed immediately behind the driver's seat, is oval in shape, with sufficient head allowance to dispense with pressure feed. The gear lever is placed inside the front door, with the brake lever placed on the outside, thereby reducing the width of the body, which is fitted with a cowl in the front for better protection of the occupants. The equipment of the Roadster includes a trunk placed on the rear with suitable covering for protection of the contents. It is surprising how dust will find its way through the smallest crevice unless such a covering is provided.

The general appearance of the front of the touring car can be seen in Fig. 3, showing the headlights carried on offset brackets with a tie bar so that no interference will upset the efficiency of the cooling qualities of the radiator. The bodies are made in the factory, and are somewhat unusual in that instead of being built up from different woods, with sheet metal panels, the base together with the door frames and doors are made from cast aluminum.

The general aspect of the chassis can be gleaned from Figs. 4 and 5, showing the right side and plan views respectively. The chassis suspension as seen in Fig. 4 is taken care of by semi-elliptic springs on the front and full elliptic springs on the rear, the lower half of the latter being clamped to a bracket which is free to oscillate around the axis of the axle casing. The rear springs are 40 inches long and 2 inches wide. The front springs are 35 inches long and the same width as the rear springs, but instead of being placed on the axle equidistant from the front and rear they are 15 inches from the front and 20 inches from the rear, which allows of carrying the radiator on the plane of the axle.

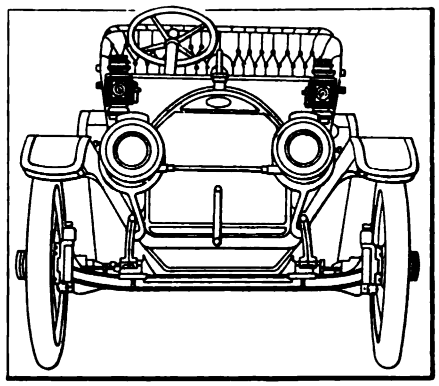

Fig. 3—Front view of the five-passenger touring car, showing the offset lamp brackets

Three-Point Suspension Supports the Motor

The plan view of the chassis (Fig. 5) discloses the disposition of the various working parts and the tapering of the frame from a broad section beneath the dash toward the front and rear together with the general arrangement of the brake levers and the radii rods.

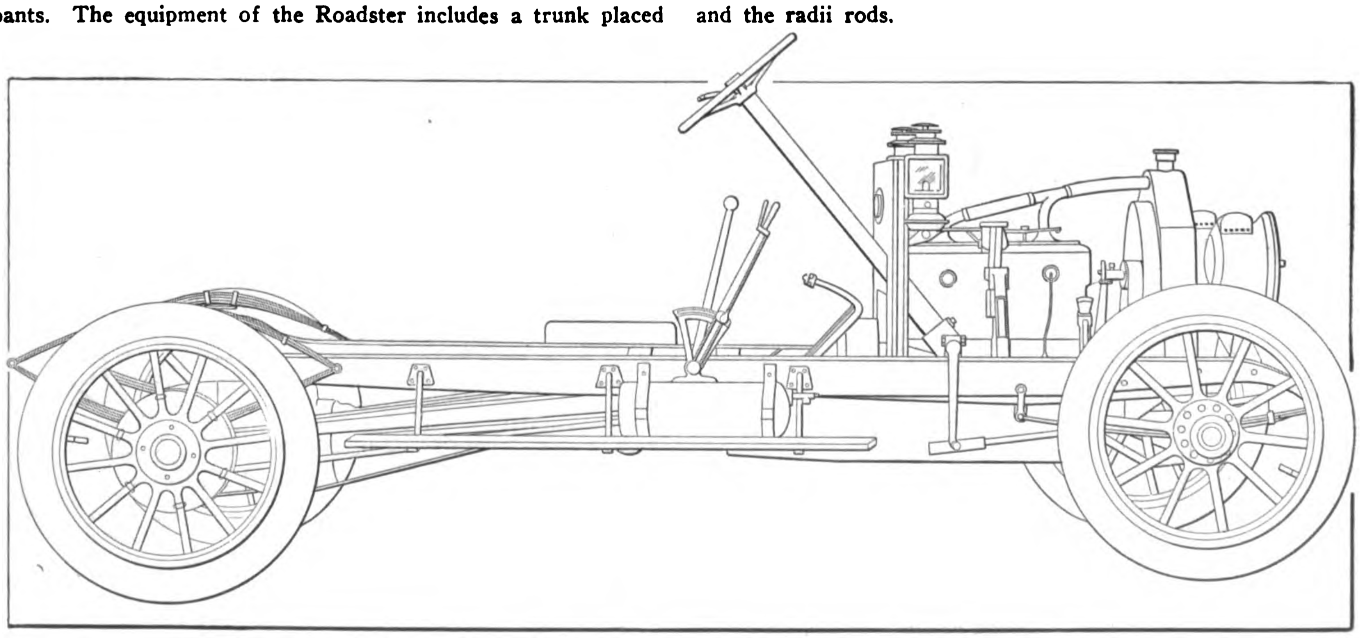

Fig. 4—Chassis of the Marmon "Thirty-two," showing method of suspension—semi-elliptic springs on front and full elliptic on rear

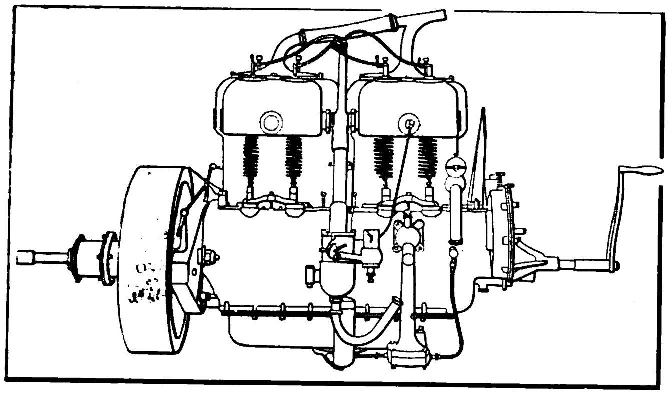

Fig. 6—Intake side of the motor of the Marmon "32," showing the low-hung carbureter

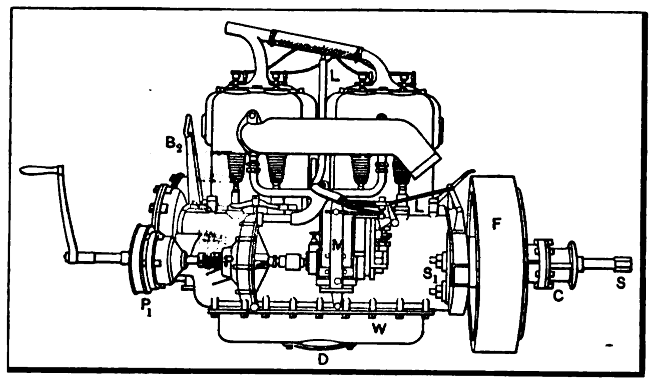

Fig. 7—Exhaust side of the motor, showing method of driving the pump and magneto

The four-cylinder motor is of the four-cycle type, with the T-shaped cylinders cast in pairs. The bore is 4½ inches and the stroke 5 inches. The cylinders are cast from a special grade of iron, with the exhaust and intake valves on opposite sides. The crank chamber is of the barrel type with a separate bottom serving as an oil reservoir, both of which are aluminum castings. One of the features of the Marmon motor is the intake manifold. One pipe is taken from the carbureter and is attached to the cylinders on the side between the two cylinders by means of locking rings. This virtually transforms the intake passageways of the cylinders into a hot-water jacketed manifold, permitting good carburetion at slow speeds as it eliminates condensation.

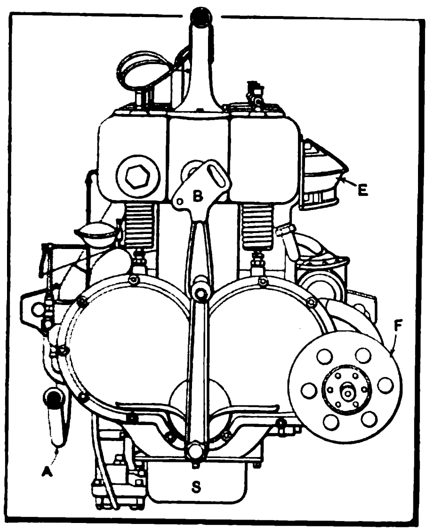

Fig. 8—Front of the motor, showing the form of valve tappets used and method of securing the valve springs

The front end of the crank case is extended, affording a bearing for the starting crankshaft. The motor is mounted with a three-point support, the forward end attached to a trunnion resting on the channel cross-member and the rear end is carried by a pressed-steel support, S_1 in Fig. 7, the ends of which are attached to the main chassis frame. In order to obtain a straight line drive the motor is inclined slightly towards the rear. The crankshaft is a steel forging of ample section (Fig. 9), with three main bearings.

Fig. 6 shows the right-hand side view of the motor and the low-hung carbureter. A Schebler carbureter of the water-jacketed type is employed to provide the mixture, the water being furnished for the heating through a copper pipe from the front pair of cylinders, a cock being placed in circuit to shut off the supply if desired. The oil pump can be seen in the illustration driven by gearing off the right-hand camshaft; a breather being fitted at the front end of the crank chamber to pour the oil into the base as may be desired. Fig. 7 shows the method employed in driving the pump and magneto. On an extension of the camshaft in front of the half-time gear case there is a pulley which through the intermediary of a flat leather belt drives the fan placed behind the radiator and attached on the bracket B_2. The pump shaft has an Oldham coupling to facilitate dismantling, and the magneto M is driven by an extension of the pump shaft which also has an Oldham coupling. In order to remove the magneto M all that is necessary is to loosen a thumb nut that holds a spring steel band in position and the magneto can be lifted off the shelf on which it rests. The valve tappets have screw and locknut adjustments and are fitted with hardened steel rollers riding on the cams. The tappet guides, turned out of white brass and held in place by a pair of crow feet are fitted with dust caps over the tops. The form of tappet used may be seen from Fig. 16. The tappet T accommodates the screw A; at the other extremity there is a roller R which has a bronze bushing mounted on a hardened steel pin. The guide is slotted to accommodate the flat sides of the tappet foot and thus prevent it from turning. The valves V and V1, for the intake and exhaust respectively, are interchangeable and have taper seats. The method of securing the valve springs can be seen from the same illustration. A counter-bored washer C fits over the valve stem and a small steel washer made in two halves fits into the grooves in the stem. The counter-bored washer fits over the split washer, holding the spring securely.

The motor is cooled by means of a cellular radiator supported on a trunnion. A dual system of ignition is employed using a high-tension magneto and a single coil, the latter being placed on the dash. The commutator in the magneto is utilized in distributing the current to the spark plugs, which are placed over the intake valves, in the event that the battery is used either for starting or emergency. The water pump is of the centrifugal type, of ample dimensions and has a tap placed at the lowest point of the circulation to drain off all water when this is found desirable.

The piston rings, which are of the triple expansion type, are

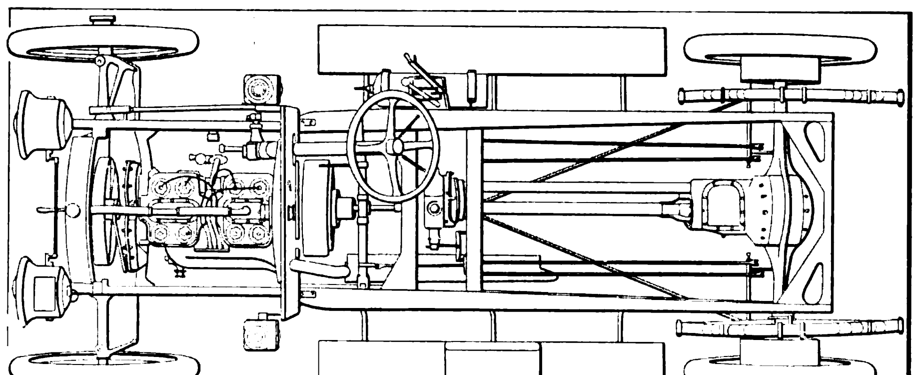

Fig. 5—Plan view of chassis, showing the taper frame and the disposition of the working parts

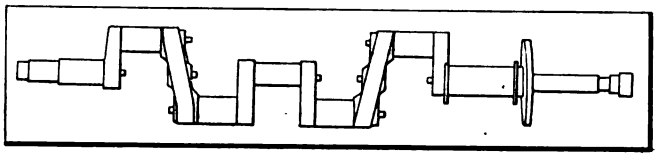

Fig. 9—Crankshaft of the Marmon is a single steel forging of large dimensions

shown in Fig. 11. They consist of two narrow rings placed over a wider ring and pinned to prevent oscillation. The wide rings R1 can be seen dismantled from the two narrow rings R2 and R3, R representing the assembled unit. The method of slotting the narrow rings in order to accommodate the pins can also be seen.

The part section of the motor shown in Fig. 10 shows the system of oiling used. The gear pump P, driven off the half-time shaft, draws oil through the lead A from the well in the base chamber through a screen and forces it through the pipe B to three main leads into the hollow crankshaft by means of the pipes M, C, D and K. The oil is then forced under the pressure exerted by the pump into the big end bearings of the connecting rods and up small copper pipes G and G1 to the wrist-pin bearings. The pressure of the oil can be regulated by a conveniently situated valve alongside the pump P, and the gauge G2 placed on the dashboard shows the pressure of the oil passing though the system. The pump is placed outside the crank-chamber and is readily removed. In order to register the amount of oil in the base there is fitted a float and level gauge O provided with a glass window. The big ends of the connecting rods dip into troughs and lubricate the cylinders and other working parts not lubricated under pressure by splash. The breather B1 is fitted with a hinged cover and the gases that escape past the pistons are given free egress through the orifice O1.

A cone clutch engaging in the flywheel is employed to transmit the power from the crankshaft to the transmission, which is located in the same housing with the rear axle and differential. The male member of the clutch is of cast aluminum, having an asbestos fabric covering riveted thereto, with relieving springs under the fabric to take the shocks of starting. The engagement is effected by means of a spiral spring located inside the chamber C in Fig. 7, and the thrust is taken by a ball bearing. The rear axle transmission unit is shown in Fig. 12. The propeller shaft is housed in the tube, the forward end of which is carried in a large ball-and-socket support within a dust and oil-tight aluminum housing on a cross member of the frame. Within the ball joint B2 is a universal coupling connecting with the drive shaft, and a second universal joint is placed forward within the clutch. The torque is taken by the main tube and the ball-and-socket joint. The pull-and-push braces R and R1 from the axle ends to the forward end of the tube hold the axle securely in right angle position, and truss rods with adjustments

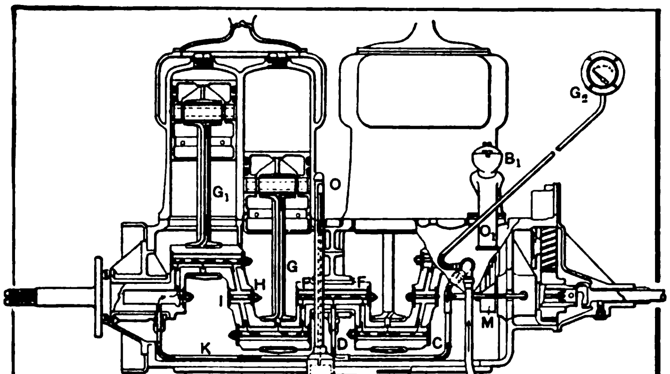

Fig. 10—Part section of the motor, showing the system of lubrication

pass from the center of the axle underneath the gear box to the forward end of the tube casing and under the axle proper, adding strength and rigidity to the structure. The box T contains the gear set, which provides three forward speeds and reverse. The oval casing T2 encloses the gear-operating rods which terminate in the front at A1. A cover C is provided over the transmission in order to replenish the lubricant therein from time to time. The rear end of the transmission casing is bolted on to the pressed steel axle casing at B1. The axle as presented shows the wheels removed and discloses the two internal expanding brakes that operate inside the same drum. The rear end of the differential housing is formed by an aluminum cover which when removed gives ready access to the working parts.

The disassembled parts of the transmission and the differential are shown in Fig. 13. The square sliding shaft with the pinions attached is shown at P and the shifting arms A and A1 may also be seen. The layshaft running on ball bearings is shown at S. A steel plate with integral bearing supports C and C1 for the journals of the differential, which also carries the adjustable pinion bearing and the rear bearings of the transmission gear set, is bolted within to the forward opening of the axle housing, and it is the removal of this plate through the rear opening which permits the easy and quick removal of the transmission.

The axle is of the floating type, the drive shafts are of large dimensions and are made of chrome nickel steel with square inner ends S1, Fig. 12, which slip into the differential and the integral flanges at the outer ends, riveted to flanges bolted to the outside of the wheels. The rear wheels run on a single ball bearing of ample dimensions. The brakes are placed parallel inside the rear drums on the rear wheels.

A side view of one of the sets of brakes seen with the wheel removed is shown in Fig. 15. The brakes are of the internal expanding type and operate within a drum 14 inches in diameter, the width of each of the shoes being 2 inches. The shoes are faced with asbestos fabric and the ends of the shoes are fitted with slots that correspond with the spacers D, D1 and D2, which with the aid of springs S and S1 give to the whole a floating ring construction and prevent chattering and rubbing when the brakes are not in operation.

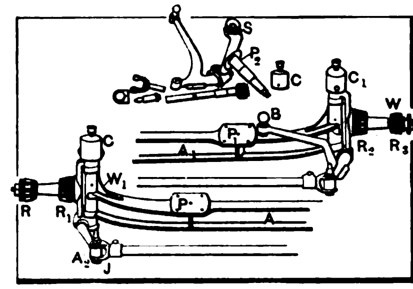

Fig. 14—Showing the front axle assembly and steering knuckles

The adjustment is effected by means of altering the position of the operating cam C by means of a worm and sector placed under the front floor boards, a separate adjustment being provided for the foot and emergency brakes. The brake drums are of pressed steel, being secured to the wheel hubs by means of bolts and clips to alternate wheel spokes.

The front axle is shown in some detail in Fig. 14, from which it can be seen that it is an I section drop forging as indicated at A and A1, the spring perches P and P1 being forged integral therewith. The steering yoke S and the spindle P2 are also drop forgings, and the point of attachment of the yoke to the axle is strengthened by means of the web W1. Ball thrusts are fitted inside the head to take the weight of the load and a dust cover C is provided, into which is screwed a grease cup for lubricating purposes. The tie rod is situated behind the axle and is attached to the arms A2 by means of yoke forgings that are threaded and screwed inside the rod; a split clamp is fitted and held firm by means of a bolt.

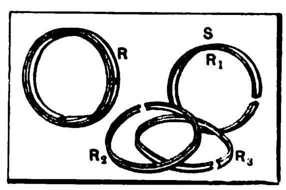

Fig. 11—Showing the triple-expansion piston rings

The pins that pass through the yoke and attach it to the lever arm are of hardened steel working in bronze bushings and fitted with oil cups. The wheels are carried on roller bearings R, R1, R2 and R3, and are attached to the spindle by means of a nut N and a washer.

The wheelbase of the standard model is 120 inches and the tread is 56 1-2 inches. The clearance allowance has been well thought out and has been fixed at 10 inches, which should be sufficient for the average road over which automobiles are intended to travel with safety. The road wheels are of the artillery type, 34 inches in diameter; but 32-inch wheels can be had if the purchaser so desires. Quick detachable rims are fitted to all wheels and these are shod with 34x4-inch tires. The weight of the car is 2500 pounds with the tanks filled but without passengers.

Oiled Roads in Canada

Dominion highway authorities are satisfied that crude oil sprinkled on the roads has demonstrated its value as a dust preventer. The city of Toronto has discarded the use of water entirely in sprinkling certain streets, and has substituted a light oil with an asphaltic base.

THE highway authorities in Ontario Province, Canada, have come to the conclusion that crude oil sprinkled on macadam roads is proving itself a very satisfactory material for keeping down dust. They have also declared that by this means the damage done to adjacent fields of grain is greatly diminished. Toronto city makes use of oil to a wide extent, having discarded water altogether for sprinkling certain streets. The authorities say that they prefer oils with an asphaltic rather than a petroleum base. The oil is sprinkled from a cart—scattered and not allowed to collect in pools—the cart being driven at a fairly rapid pace. A man sometimes follows the cart with a broom to brush away any pools that may collect. A mixture of crude oil and limestone dust makes a toughened skin over the roadway, preventing dust and preserving the metal surface. Two or three applications of oil within a fortnight early in the Summer and then four or six weeks apart will suffice. About 1,500 gallons per mile will make the first three applications on Toronto streets, 24 feet wide. These oiled highways are the joy of automobilists.

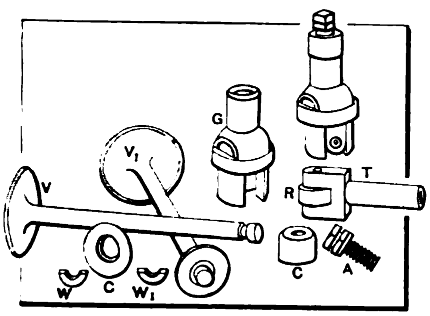

Fig. 16—Assembly of the Marmon valves and tappets

CARE OF SPRING SHACKLES.—Spring shackles cannot fulfil all the conditions required in connection with a fast-running vehicle on a rough road; they may mitigate many of them, and if there is not great care exercised in the design and application, they may very easily greatly exaggerate evils they were intended to cure or prevent. The ends of the main springs are the points of connection with the chassis frame, and all the shocks which pass the tire and the main spring are transmitted through these points.

The wearing away of these parts is inevitable, and cannot, under any conceivable circumstances, be avoided. The arrangements made for lubrication, etc., greatly mitigate the wear, but it is taking place in a greater or less degree all the time the car is in use. The wearing away of the bolts and shackles is the result of friction concentrated frequently on small surfaces. The load over the springs is responsible for the pressure and the speed at which the car is being driven for the rubbing friction; the smoother the rubbing surfaces the smoother the working and the longer the time which they resist wear.

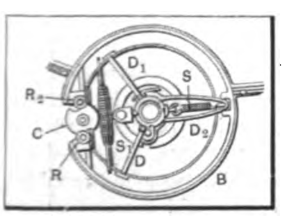

Fig. 15—End view of the internal expanding brakes

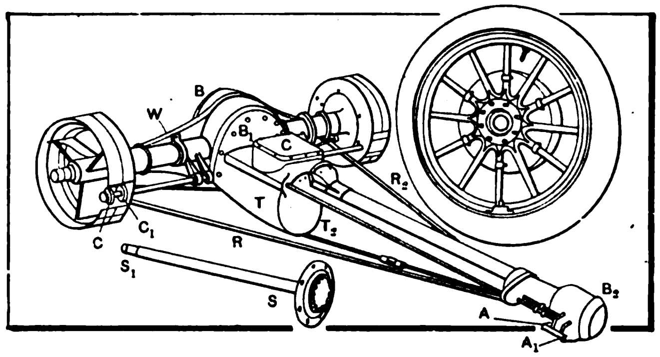

Fig. 12—Rear axle transmission unit, with wheels removed and showing the internal expanding brakes

"Soft" or "Nervous" Motors

A well-known engineer states that the discussion of motors coming under the above popular classification resolves itself down to a question of torque, and that under given circumstances resemble each other strongly.

THE distinction between "soft" and "nervous" motors, says A. Contet, is devoid of genuine merit and is dictated mostly by commercial considerations. A "nervous" motor has all the characteristics of a "soft" motor when overloaded. The question is one of torque at the various motor speeds. The torque of the short-stroke motor (or 110 by 120 millimeters) of the heretofore ruling design is generally superior below 1,500 revolutions per minute, while that of the long-stroke motor, developing the same power with 85 millimeters bore and 160 millimeters stroke, is superior above 1,500 revolutions per minute. With regard to the bearings of the long-stroke motor, Contet maintains that their rapid wear is simply due to the erroneous practice of using only two bearings for the shaft of a four-cylinder motor, which compels the use of very large diameters and consequently rapid wear of connecting rod bushings, due to the high linear speed. He considers that every "pushed" or "nervous" motor should necessarily be equipped with five crankshaft bearings for four cylinders, so that crackpin diameters may be reduced to their minimum, and that these bearings furthermore should be ball-bearing, so as to give room for widening the connecting rod knuckles and diminishing the pressures per square inch. By this means the pushed motor may be made just as durable in all its parts as the customary type.

JUST at the present moment there is an attitude of uncertainty among the automobilists of Canada, because of the changes which are apt to be brought about in the event of new tariff regulations going into effect. It is estimated that the duty on motor cars would be reduced at least 5 per cent.

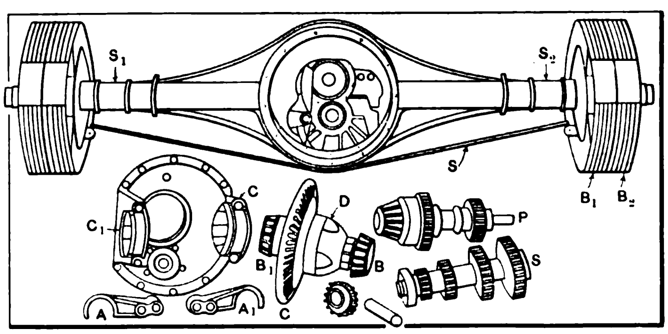

Fig. 13—Showing the Marmon transmission and differential disassembled

Power Plant for a Country House

A small plant may be installed in a country house which may be used by the owner for a variety of purposes and, which will in time, be found to more than pay for itself by cutting down repair and lighting bills as well as in convenience.

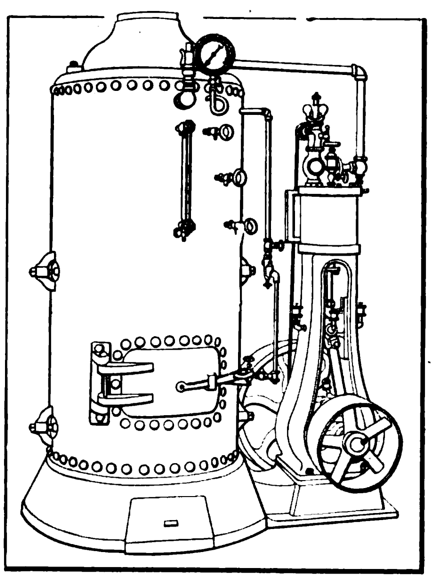
THE man who lives out of town all year is bound to find time, especially in the winter, when he would be able to put in some useful work on his automobile if his garage were heated or illuminated properly. There are so many things to be done about a country house for which a power plant of some sort is a necessity that it is very easy to secure a central plant which will take care not only of the garage and its appurtenances, but also of much of the other work, such as pumping, lighting and churning. The plant installed will, of course, be more or less elaborate according to the necessities of the particular case in point.

A small shed may be built in connection with the garage in which the boiler and engine may be installed. As illustrated in the cut, the engine is on the same base as the boiler and thus occupies very little floor space; an engine producing four horsepower, with the boiler, taking up very little room. Adequate clearance must be provided in installing the boiler to allow of easy stoking of the fire in the boiler.

From this engine may be driven a dynamo which will be sufficient to not only light the garage but the house as well. The engine may be used whenever it is desired, thus making for greater economy and a reduction of lighting bills. Besides doing the lighting, a belt may be carried into the garage which will run a main shaft, from which may be driven a small engine lathe or any other tools required, such as drill presses, etc.

In the Winter time it would be a simple matter to run a steam pipe into the garage from the shed, thus providing a simple and safe method of heating the garage under all conditions of temperature; and work which would otherwise have to be held over until more suitable weather conditions prevailed may be carried on in the most severe parts of the year.

The greatest advantages of a plant of this type over taking the power from a service line is that it may be used for anything the owner may desire, and that one will be able, with the same apparatus, to do all the heating as well as the other work at the very time it is desired. The power does not have to be paid for when it is not in use, as is often the case when taken from a service line, and it is not cut off at a certain time at night because a full moon happens to be announced by the local almanac. With a garage fully equipped with lathes, drill presses, etc., the cost of upkeep of the automobile would be reduced to a minimum. Valve grinding and all the other operations of repair and adjustment, instead of being done outside, may be made by the mechanician or chauffeur at home with much greater dispatch and under the supervision of the owner of the car. Paying for unnecessary repairs of parts will be avoided.



Illustrating a small steam engine and boiler situated on the same base, presenting a very compact and efficient plant

Another use to which the power plant may be put is in driving the water pump. The gas-engine water pump has been found to be very much of a nuisance owing to the very unpleasant noise which generally accompanies its work. A water pump which will be very silent may be driven by belting off the engine.

As to Road Building

Being a set of meditations on the nature of good roads, some conditions of their construction and an unusual way of looking at the problem of building them. Contending that history repeats itself, some principles will have to be followed in order to solve the question facing our time at the minimum expense of time and money.

DURING a recent meeting held in the South relative of the Good Roads movement, one of the speakers made the appalling statement that had such a meeting been possible half a century ago the Civil War would not have been necessary.

Knowing but this one passage of the speech in question, it is of course impossible to see just what consideration prompted the utterance quoted; nor is this the place to debate as to whether the statement was a well-founded one or not. But there is hardly a doubt that, had transportation facilities been different from what they were at the time of the war, history would have been written differently.

Since necessity works in history the same as it is active in the functions of an engine, it must be assumed that the development of history, as brought about by the Civil War, was a necessary one, and perhaps a beneficial one, despite the fact that the best of America's manhood was sacrificed thereby and evolution thrown back for fully a generation.

Coming back to the subject of good roads, it will have to be granted that the best roads in existence to-day are the Roman roads on one hand, and some constructions of later periods on the other, among which the Napoleonic roads deserve special mention. For the success of the Roman and the first French empire these good roads were a *sine qua non,* and it remains to explain the possibility of such enormous engineering feats at times when there were less humans available than at present.

The answer is that the cost of constructing these roads was comparatively insignificant, since the roads were built by either soldiers who were paid little in addition to what they had an opportunity of taking from the enemy, or by slaves whose support was but the cost of feeding them, food also being acquired without any expense in most cases. It was by the cheapness of labor that the construction of really good roads was made possible, and this state of affairs more than balanced the lack of powerful appliances at the time of building the Roman roads. As to the roads built under Napoleon Bonaparte's regime, there are quite a number of them in Europe, they being the only good roads in their respective territories. It is a moral certainty that the French did not pay cash for the labor involved in the construction of Napoleonic roads; but Bonaparte seems to have carried out the antique principle of forcing the vanquished to his services.

Comparing the great ancient roads of Italy, France, Western Germany and Britain with the modern constructions, the thought forces itself upon us that works like the Pyramids or the Church of Notre Dame could not be paid for when they were built, nor could they be built to-day if payment should be required.

It seems that the construction of truly first-class roads cannot be enforced except during such cruel and tyrannic periods as those of Caesar and Napoleon. For public comfort is too nice a thing to be disturbed for the sake of public benefit, and discipline is next to impossible in any free State, the one exception in history being the case of the Roman republic. Whether the severe principles then in vogue paid for themselves is left to the student of history to decide.

Patent Truths Concerning Varnishes

Discussing the Phases of Automobile Finishing

M. C. Hillick goes into the ramifications of varnishing work, discussing the merits of the methods in vogue and dwelling upon the shortcomings that are occasionally indulged in to the detriment of the results obtained. This article is intended to be helpful to the man who owns and operates a car, without in any way interfering with good workmanship as it obtains in plants of some distinction.

WE borrow trouble, carry burdens, and wince under the yoke of many things connected with the wear and tear of the automobile, but not infrequently lose sight altogether of a main source of expense. At present there is a great gulf fixed between the automobile owner and the garage zouaves, and to cross from hither to yon, or vice versa, means an expense, figuring in the aggregate, which the man of moderate means is not daring enough to face. The item of large expense here referred to, and for which the garage employee, or the understrapper around the livery barn, or the man-of-all-work infesting the premises of the car owner, is largely responsible, is that of varnish abuse. As explained in a former article, varnish, and especially the finishing coat, is at once the most expensive and the most sensitive material that finds an outer point of vantage upon the surface of the car. At the same time, under fair treatment it is one of the most durable things which serve to protect and beautify the car.

It would almost seem, taking a broad view of the situation today, that a campaign of education is needed to insure for the varnish fabric upon the car a manner of treatment entirely free from abuse. Prejudice, deep rooted habits, generously mixed with ignorance concerning the vital essentials in the care-taking of varnish, are the traits of human nature entering into the practice to discourage which this article is written.

Varnish has very much of human nature in its composition and to go on eternally heaping upon it all the forms of abuse listed in the catalogue of cruelties is to invite a volume of expense at which even the millionaire has a right to balk.

To begin right with varnish after it has been flowed and fashioned upon the surface with the good practice of the brush artificer it should in no way be disturbed or exposed to service until it is dry and firm enough to take a generous water bath without bruising or clouding it.

And this water bath, let us understand at the outset, should not be forced through a high-pressure hose held at an angle to strike the surface with the force of a solar-plexus. Rather should it be a gentle flow of water distributed, if preferred, through the hose, and given a light pressure wash with a soft wool sponge. Let the water be clean and moderately cold, and after sponging the surface thoroughly dry it off down to a water mist with a soft, clean, wash leather which you buy of the jobber under the name of chamois skin, although it was more than likely cut from a Colorado sheep pelt.

All this suffices for a first washing, and this should be followed as often as the car goes out and accumulates a plaster of road dust or a smear of mud, either of which mediums is destructive to the varnish if allowed for any length of time to remain upon the surface. The ammonia with which roadway accumulations are saturated, working in connection with other alkalies, and deleterious substances contained in dust and mud, are highly injurious to varnish. Indeed, there is no other agency, except hot water and fire, which will break down the brilliancy of varnish and permanently destroy its luster so quickly.

The need, therefore, of frequent water baths, applied in the manner described, is apparent. The abuse consists of first permitting these acid and actively destructive accumulations to dry and bake upon the surface or in washing them off with a powerful volume of water hurled at the surface at a high pressure. Abolish these two forms of abuse and you have cleared up two threatening and dangerous phases of the situation.

The next inexcusably bad practice consists in cleaning, or attempting to clean, the surface with waste or cloths saturated with various oils and smeary preparations, not a few of which are no more adapted for renovating or imparting life to the varnish than a skiff is suited to sail the high sea. All such mediums are too harsh and erosive in their effect upon the delicate field of varnish and they very soon nip off the sharp brilliancy which goes as a part of the well-finished surface.

Various emulsion cleaners have been, and are now being, recommended for the car surface to keep it bright and clean and to make the varnish wear longer. All such suggestions should be accepted by the motorist with several grains of allowance.

As to the merits of emulsion cleaners for the varnished surface upon the automobile, the question arises, What is the nature of an emulsion cleaner? Apparently some misunderstanding exists concerning this matter. An emulsion cleaner, under reasonable interpretation, carries ingredients consisting of water and alkalies, and, it may be, of acid. Moreover, it may also contain a percentage of oil. The oil is added in the case of some cleaners to neutralize the effect of the alkali, or the acid, or both. All such cleaners, however, are sooner or later—generally sooner—destructive to the varnish, and they should under no circumstances be used for automobile cleaning or renovating purposes. If you really wish to injure the surface to the extent that you would injure it with one of these innocent-looking emulsion cleaners, use common bar soap and water and save 90 per cent. of the cost of the emulsion cleaner.

If resort must be had to a cleaner other than water and possibly some light renovating body such as may be used upon pianos when the varnish has reached a certain stage of wear, employ a straight oil cleaner free from water, alkali or acid.

In any event, it is well to understand that a cleaner, be it oil cleaner or oil emulsion cleaner, or something masquerading under a more alluring title, should have nothing in its composition to blight or decompose the varnish. A straight, clean, soft-water bath applied to the car in the manner already directed is the very best treatment that can be given the varnish—as a matter of fact, it is the only treatment that should be permitted or tolerated—so long as the surface holds firm and intact and retains a fair degree of its original luster.

Reaching an advanced age the varnish may then, if so desired, be "flushed up" with some mild renovating medium containing a certain cleaning element in connection with a renovating and gloss-restoring ingredient.

Nevertheless, the sum of the whole matter is not to choke or throttle the varnish in the days of its youth by feeding it upon divers dopes of uncertain pedigree. Rather simply keep it clean by the application of water and common sense until the stage of decline sets in, whereupon either give it a fresh coat of varnish or apply frequently a renovating medium of established beneficial qualities.

Practical Automobile Repairs

Calibration of Parts Is Vital

Time is fast drawing nigh when it will be possible for the amateur to repair his own car with moderate success, but it remains for the manufacturer to co-operate with the owner and deliver parts that will not require a greater deal of fitting. When parts wear it cannot be expected that a new part from the factory will just fall in and be a perfect fit. It is no use putting a square peg in a round hole.

THE cry of standardization has been taken up wholeheartedly, and with the co-operation of manufacturers it will not be long before makers will have stocks of parts in different sections of the country, so that an owner of a car who finds himself in need of a new part to replace a broken or worn one will be able to obtain what he wants within twenty-four hours. It is still within the memory of many that one had to wait sometimes weeks for a spare part and in the case of some foreign cars the time bordered on the indefinite. This was an unfortunate state of affairs, but neverthless it has been to America's advantage.

The manufacturer's responsibility does not end with simply supplying a new part speedily. It would be hard to find anything more exasperating than after waiting for several days, perhaps held up in some country town, to find that the part sent was not the one ordered, or that it was a case-hardened part several thousandths of an inch too large. Such examples have been by no means of uncommon occurrence in the past. A case in point was recently discovered in a race, where the clutch thrust raceway, which was made of three parts, had become overheated and seized, necessitating the replacement of a new part, which in the ordinary way could be performed in ten minutes. The new raceway was offered up to the hole in which it had to fit and it was found that it was a matter of 0.0005 of an inch too large in diameter, and the unfortunate car was placed out of the race.

Jig work is fast becoming the usual method of manufacture in up-to-date shops, but a good deal depends upon the intelligence of the workmen in this rule-of-thumb method. One man is given a machine and a jig and he works from morning till night upon the same job, as, for example, drilling holes four at a time in a certain part. The drills must enter where the jig directs and the part must drop into the template or jig, but unless the locking of the jig is carefully executed the forethought of the designer will be nullified by an error that can only be found out in the running of the car.

Take, for example, the part shown at P in Fig. 3. This part connects the clutch to the transmission by means of an intermediary collar that fits over the squares of the part P and a corresponding part attached to the extension of the transmission shaft. The holes are drilled by two successive operations usually, or could all be drilled at the same time, for that matter. If the

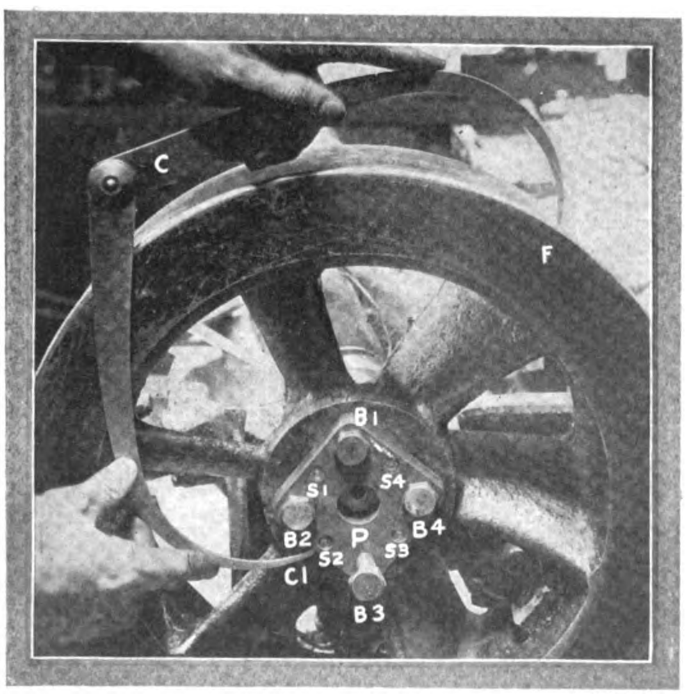


Fig. 1—Method of calibrating the part that has been attached by means of studs and bolts to the flywheel boss for concentricity

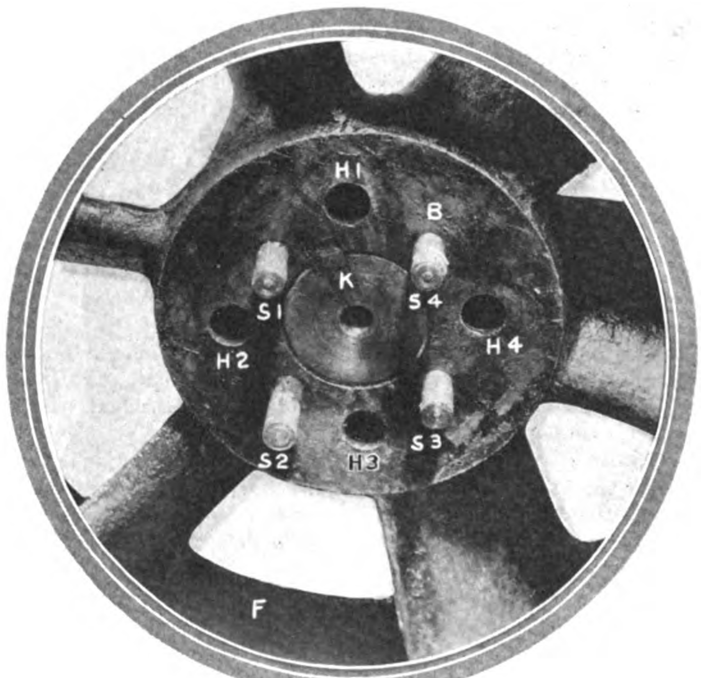

Fig. 2—Boss of the flywheel showing the studs that have been damaged through incompetent fitting

work is properly done, the fitter, when he comes to assemble the part to the flywheel F, will find that the holes S11, S22, S33, S44 correspond and register with the studs S1, S2, S3, S4, respectively. Then come the holding bolts that pass through the plate P through the holes H11, H22, H33, H44, and screw into H1, H2, H3, H4, respectively, and they may fit all right. The general appearance of the assembled parts is shown in Fig. 1. There still remains, however, the vital part of the work to be performed, and that is the outside calibration to correspond with the holes and studs and bolts. The alignment of the motor and transmission is dependent upon this, for unless the alignment is perfect there will be undue wear on the universal joint and the disalignment may even cause a disagreeable knock at high speed. Incidentally, the part, although case-hardened, will wear and require replacement.

The case in point shows a Winton flywheel and the method employed in the shops and service departments of determining if the concentricity has been maintained in manufacture. Calipers are found useful in many ways on the car and in the garage of the private owner, as with this tool many small differences can be detected and wear located which otherwise could not be seen with the naked eye.

Shafts that are delivered by factories should have the centers left in them whenever possible, as it is difficult for the amateur

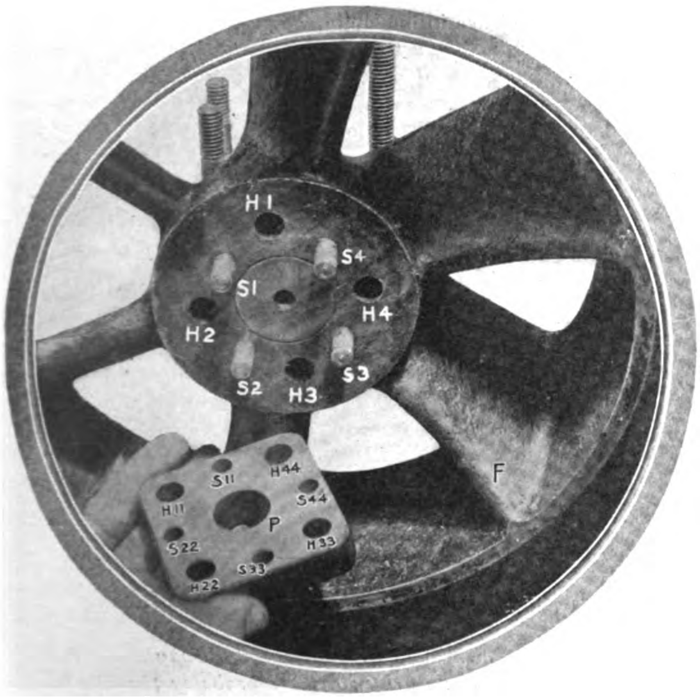

Fig. 3—Showing how the square block is attached to the flywheel and although it may fit on the studs properly, the outside squares may need dressing down

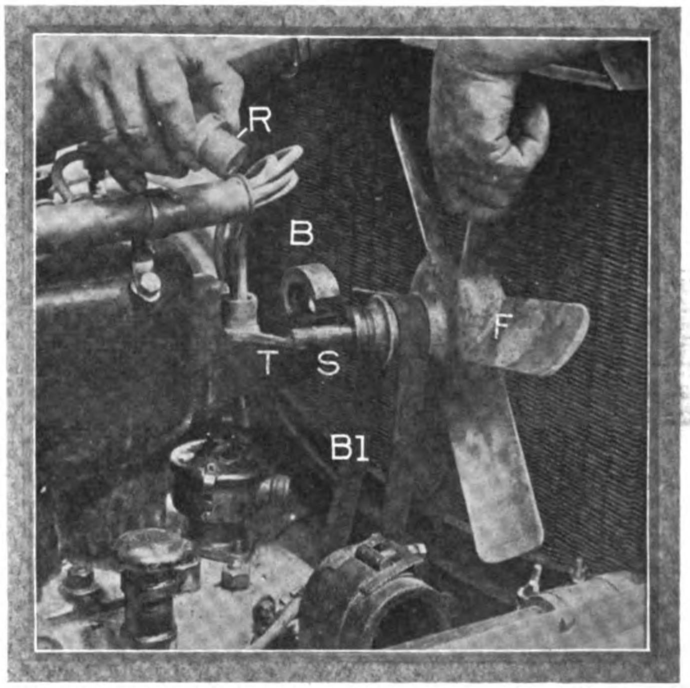
to recenter them. Fig. 2 is offered to show what might take place if the spare part were delivered with the holes badly drilled. If it were hammered on obliquely, as was the case in this particular instance, the studs will be burred, as may be seen at S4, and in a lesser degree at S3. Makers cannot be responsible for carelessness and want of experience on the part of operators of cars, and it is often better to let someone do the work properly in the first place rather than create work in undoing what has already been badly done.

Inaccessibility of Fans

UNLESS the method of drawing the air through the radiator to cool it is carried out by means of veins in the flywheel, the usual method employed is to drive a fan placed in front of the motor by means of a leather or metal belt. The disadvantage of the metal belt is that it is apt to snap, whereas the leather belt, be it either of the twisted-hide or the flat variety, as here illustrated, will in time expand and require taking up. This is effected by various means, but when it is a question of removing the belt to take out a portion owing to the stretch that has taken place, this part of the work very often entails a good deal of trouble.

The best form of belt is one that has been sewn previous to being used on the car, and the method seen in the illustration of dismantling the fan and its attachments greatly facilitates matters. The spindle S passes through the slot of the bracket B, and the bush R, which has a hole drilled eccentrically to accommodate the spindle S, fits inside the bracket and is locked by a nut placed on the threaded end of the spindle. This operation, under the circumstances, should not take above a couple of minutes, and if the belt is not tightened after it has stretched the friction will wear the fabric quicker than if it was driving under tension.

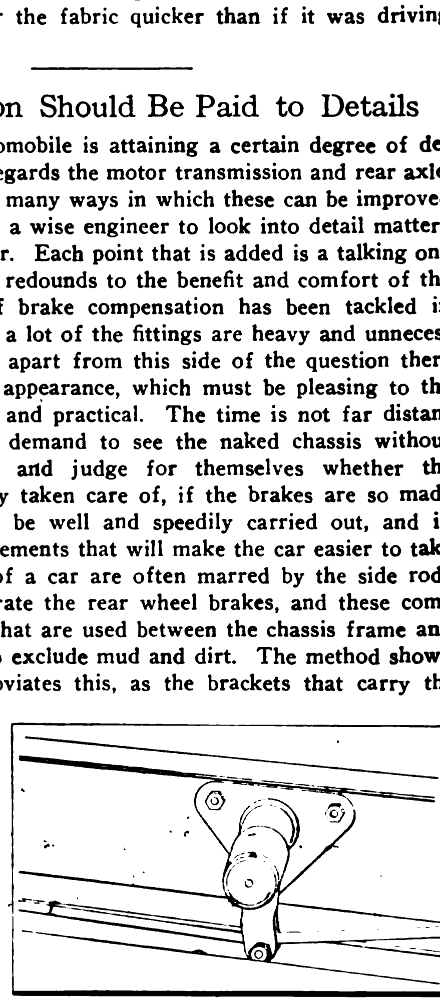


Method of attaching the fan to a bracket on the motor whereby ready dismantling is possible

More Attention Should Be Paid to Details

NOW that the automobile is attaining a certain degree of definite form as regards the motor transmission and rear axle, not that there are not many ways in which these can be improved upon, it is the part of a wise engineer to look into detail matters appertaining to the car. Each point that is added is a talking one for the salesman and redounds to the benefit and comfort of the user. The matter of brake compensation has been tackled in many ways, but quite a lot of the fittings are heavy and unnecessarily clumsy. Quite apart from this side of the question there comes the matter of appearance, which must be pleasing to the eye as well as useful and practical. The time is not far distant when the public will demand to see the naked chassis without body embellishments and judge for themselves whether the lubrication is properly taken care of, if the brakes are so made that adjustments can be well and speedily carried out, and in general look for refinements that will make the car easier to take care of. The sides of a car are often marred by the side rods that are used to operate the rear wheel brakes, and these come outside the valances that are used between the chassis frame and the running boards to exclude mud and dirt. The method shown in the illustration obviates this, as the brackets that carry the arms are inside the frame, and consequently out of sight.

The bracket is similar to the type usually fitted outside the chassis frame but is less likely to be clogged up with mud. The cross-shaft is not shown in the illustration.



Method of carrying the bracket for the brake levers inside the chassis frame

It Stands to Reason—

(Applying Reasoning Power to Difficult Situations)

In the face of a difficulty it may be the part of wisdom to resort to "presence of mind," or profit may come through the use of strategy—in either case the mind must be nimble, and to obtain this condition is a mere matter of practice.

THAT haste makes waste, excepting in the lubricating of an automobile, where no time is to be lost.

THAT the constituency of a chauffeur is made up of the mechanisms under his charge, and if he wishes to retain the good opinion of his constituency he must diligently court that opinion.

THAT the constituency of the owner of an automobile is made up of the car itself, the chauffeur, and the repair-man—it may be wisdom on the part of the owner to include his banker in the coterie.

THAT the fragmentary information that the average salesman imparts gratuitously to a prospective is scarcely sufficient to clinch an argument to the satisfaction of a conservative person.

THAT positive statements of alleged facts are the tools of those who are not on a speaking acquaintance with silent satisfaction.

THAT a beguiling automobile may have so many "selling points" that they will become troublesome to the owner.

THAT a shapely car when taken at its true estimate will have a certain harmony of relation of the mechanisms as well as appearance.

THAT a villainous automobile will not begin to make a noise until the maker gets his check.

THAT the man who can be lured by a decoy is pie in the hands of the glib-tongued agent who would foist a second-hand automobile in substitution of a new car.

THAT nothing defeats success like too much earnestness of purpose on the part of the buyer of a car in contact with the fellow who desires to get rid of a second-hand automobile.

THAT night time is the favorite for the delivery of a used automobile when it is being pawned off as a new car.

THAT the purchaser of a car will be justified in withholding payment for the same until he can look it over in broad daylight.

THAT the man who acts like a deity during the making of a sale has the devil for a wicked partner.

THAT the most pleasing thing to a cultivated taste is an automobile that lives up to the promise of a salesman.

THAT there is nothing to eclipse the reckless financiering of the man who uses tires that are too small for the car.

THAT a motor, if it is maltreated, will have ample opportunity to get back at the bully who abuses its sensibilities.

THAT the properly adorned body of an automobile is not necessarily red in color.

THAT it is easy to convict a man of imprudence if he buys a large tonneau if his neighbor has a large family.

THAT a man who has a liking for flattery may obtain the fullest measure by getting a car with more seats in it than he needs himself.

THAT the demerit existing in an automobile comes to the surface after the salesman gets through exploiting the merit.

THAT the fellow who toys with destiny to the extent of buying two bad automobiles in succession might well take himself to a dark room and study the situation over.

THAT the fellow who traded in one bad automobile for another, getting the latter from the same maker, displayed far too much confidence in humanity.

THAT adroitness on the part of a salesman may uncover a pious desire to dispose of a second-hand automobile.

THAT there are more mysteries in the world than those confined to chemistry, and a few of them are attached to the use of over-sized tires.

THAT over-sized tires should be used on all the cars of a given model if they are employed on the demonstrating car of the same model.

THAT a disinfectant will be scarcely sufficient to overcome the noise of an ill-contrived planetary gear.

THAT magnificent poetry after it leaves the hands of the demonstrator frequently displays an abnormal lust for noise.

THAT it would cost less money to overcome the troubles in a given model of a car than it does cost to keep these models sold.

THAT the man who takes an automobile back to have it "half-soled" might well make a bargain with the repair-man and have the stipulation put down in black and white.

Chains Require Attention

Of all the parts which suffer from neglect through inattention, the chains on a chain-driven car are probably the chief sufferers. There is no doubt that if the method of procedure in cleaning and oiling a chain were known, the proper attention might be given in a great many cases.

THE owner or driver of a chain-driven car should appreciate the fact that the chains need careful attention. While chains have been known to run an entire season without any care or additional lubrication, this practice is deprecated. To care for a chain properly, one should get into the habit of lubricating every so often and so time these intervals that they occur before the chain is in need of the oil. In addition to this regular lubrication, there should be some set time at the end of which the automobilist takes the chain off, cleans it thoroughly, and inspects it to detect faults.

A month is a good length of time for this, and an excellent way to proceed is to take the chain off and throw it into a pan of kerosene. In the morning, all of the dirt will have passed from the chain to the liquid and can be found in the bottom of the pan. Take the chain out and throw the liquid and dirt away. Then clean the pan and wash off all traces of the kerosene with gasoline. Having done this, hang the chain up to let the gasoline evaporate.

The chain then will be both clean and dry. Now inspect all rollers, links, rivets and bushings, taking note of any unusual wear as indicated by looseness or play. If defects are found, they should be remedied. Then, having the chain clean, dry, inspected and passed upon as O. K., an excellent method is to soak it, or, better, boil it in a heavy melted lubricant. The best quality of beef tallow mixed with a little graphite is good. Many do not like the latter, in which case a high-grade oil may be substituted for the purpose.

As to the Merits of Vanadium

Lake and Norris Vigorously Lock Horns

E. F. Lake discoursed under the caption "Alloy Steel for Automobiles" in THE AUTOMOBILE *of June 29, and George L. Norris expresses his disapproval of some of the doctrines indulged in by Lake in the article referred to, and the communication here presented gives Mr. Norris' version of the vanadium situation with which Mr. Lake generously disagrees.*

How Vanadium Looks Through the Eyes of George L. Norris

WE wish to take exception to some of the statements made in an article entitled "Alloy Steel for Automobiles," and published in your issue of June 29. From the introduction of this article we judged that it was intended to be an authoritative source of information for the automobile manufacturer and engineer.

The subject of the paper, "Alloy Steel," seems to have been carefully chosen, as the author eliminates from consideration practically all alloy steels excepting chrome-nickel. In the third paragraph of the article this statement appears: "The much-advertised vanadium steels have shown some good properties, but when submitted to various kinds of tests they have not taken the place of chrome-nickel steels." We expected to find in the later paragraphs some description of the qualities of vanadium steels, but were surprised to find the following: "Of the vanadium steels very little, if any, vanadium is present in the finished product and hence vanadium steel is a misnomer. Vanadium has great affinity for oxygen and also for nitrogen and if added to the bath just before teeming into the ladle it will seize these and carry them off into the slag. By thus scavenging out the oxides and occluded gases it retards the formation of blow-holes and the segregation of the carbides and makes the metal more homogeneous and also more easily machined. Aluminum performs a very similar mission, but yet we do not speak of aluminum steels."

While vanadium possesses a certain peculiar efficiency over silicon, aluminum and titanium as a scavenger it is not primarily used for this purpose, and the object of the steel maker is to alloy with the steel the highest possible percentage of the vanadium which he adds. The beneficial effects of percentages of vanadium varying from 1-10 of 1 per cent. up to 1 per cent. and even more have been definitely determined. Mr. Lake then continues: "Vanadium of itself adds no virtues to steel. When it has cleansed the steel of impurities it has performed its mission; thus it is as well to allow it to go off into the slag as to try to keep any in the steel, unless the steel maker wants to prove to the chemist that it is vanadium steel. That slags can be used in an electric furnace to perform the same mission of purifying the steel has been thoroughly demonstrated and this may overcome the necessity of using as expensive an alloying material as vanadium."

The experience of a large number of steel manufacturers who are producing vanadium steels regularly and the experience of the people who are using vanadium steels in automobile construction and a variety of other uses is overwhelmingly opposed to this statement and it should not have been at all difficult for Mr. Lake to have made himself familiar with the true ideas.

The steel maker before he makes a heat of vanadium steel has a fixed idea as to the percentage of vanadium he must obtain in the steel to produce certain results in the finished article. The steel that does not contain vanadium as shown by analysis is not a vanadium steel and will not exhibit the qualities, both static and dynamic, of vanadium steel. It is not a question of proving to the chemist that vanadium has been added; it is a question of having vanadium in the steel because by countless tests it has been proved that vanadium produces definite beneficial results.

The statement is made that vanadium steels have shown some good properties, but that when submitted to various kinds of tests they have not taken the place of chrome-nickel steel. Mr. Lake then proceeds to describe a chrome-nickel steel which he considers one of the best, but which is actually being looked upon with disfavor by many of the best automobile engineers and metallurgists because it is an unsafe steel. The legitimate field of Mr. Lake's chrome-nickel steel is for the manufacture of gears, and even in this field its supremacy has declined in favor of chrome vanadium steels. As for using this steel for front axles and steering knuckles we believe Mr. Lake's advice on this point is very unsound. It is true that vanadium steels, by which we mean various alloy steels containing vanadium as a component part, have replaced chrome-nickel and nickel steels to a very large extent in automobile parts. A great number of cars, including not only the low-priced machines but some of the highest-priced types, are made from steels containing vanadium. Against the opinion of Mr. Lake we quote from so well-known and universally recognized an authority as Prof. J. O. Arnold, of Sheffield, England: "Vanadium is undoubtedly the element which together with carbon acts with the greatest intensity in the way of improving alloys of iron, that is to say, in very small percentages." Professor Arnold is of the opinion that vanadium combines to form a double carbide of iron and vanadium, that it seems to have not only a chemical but a physical influence in promoting the even distribution of the carbon, and retarding constitutional segregation. He infers from this and other experimental evidence that there is strong reason to believe that very small percentages of vanadium will largely enable steel to resist the deterioration which under constant vibration leads to brittleness. This opinion of Professor Arnold's has been completely confirmed by the record of vanadium steels during the years that have lapsed since his statement, and they have well earned the name of "anti-fatigue steels." Mr. Lake's statement that slags can be used in the electric furnace to perform the same mission of purifying the steel as vanadium, and that this may overcome the necessity of using as expensive an alloying material as vanadium, can be answered most conclusively by the fact that manufacturers of electric furnace steel are to-day producing vanadium steels and making no pretense that they are able to produce steels of the same qualities without vanadium—the composition being otherwise the same. Vanadium so profoundly affects the physical qualities of the steels to which it is added, through its intensifying effect upon the other elements in the steel, carbon, chromium, nickel, silicon, etc., that these steels can properly be termed vanadium steels without misnomer.

To quote from Dr. John A. Mathews: "From a wide experience with all types of alloys, it is my opinion that where a better material than the best nickel steel is needed, and especially when dynamic excellence is sought, the appropriate types of vanadium-chrome steels may be unreservedly commended. They forge well and machine more readily than chrome-nickels of corresponding carbon percentages."

While nickel-chrome and nickel steels will undoubtedly always continue to be made, they are being replaced by chrome-vanadium and chrome-nickel-vanadium steels on account of the superior static and dynamic qualities possessed by the vanadium steels.

The widespread use of vanadium steels in automobile construction for gears, rear axles, shafts, steering knuckles and levers, crankshafts, propeller shafts, valves, piston rods, springs, etc., is incontrovertible evidence that vanadium does add to the virtues of steel, for it is inconceivable that the manufacturers of automobiles would adopt vanadium steel to the great extent they have without familiarizing themselves with its qualities.

As a matter of curiosity I would like to have Mr. Lake explain how by the crucible steel process it is possible to reduce the sulphur and phosphorus to a greater extent than by the open-hearth process.

What E. F. Lake Thinks of the Norris Type of Criticism

IN an effort to critise my article Mr. George L. Norris starts off by saying it is worthless, without offering any kind of evidence, submitting a few facts, or giving data to prove his assertions, or show that misstatements have been made. Words have been multiplied, but in his whole criticism it is difficult to get hold of any facts or real data on which to base an argument. For instance, he takes exception to my statement that "Vanadium of itself adds no virtues to steel. When it has cleansed the steel it has performed its mission, etc." In trying to refute this statement he says, "The experience of a large number of steel manufacturers is overwhelmingly opposed to this statement—it is a question of having vanadium in the steel because by countless tests it has been proved that vanadium produces definite beneficial results." Absolutely no facts or data have been presented in confirmation or proof of this statement of his and yet he says there are countless tests. Why has he not submitted one of these?

A great deal of experimenting and testing has been carried on with vanadium-treated steels and practically all of these have shown that titanium has a great affinity for oxygen and to a considerably lesser degree for nitrogen. In the manufacture of high-grade steels, carbon, manganese and silicon are made to deoxidize the bath as much as is commercially practical. After this has been done the remaining oxygen and nitrogen can be further reduced if ferro-vanadium is properly added. In doing this most of the vanadium used goes off into the slag with these gases. Enough should be used, however, so as to leave about one-tenth of 1 per cent. of vanadium in the steel. The steelmaker will then be assured that it has thoroughly permeated the bath and seized all of the oxygen and nitrogen it is possible to bring it in contact with.

In this work it has performed a useful mission and nearly all the metallurgists who have investigated it have shown that its main mission is that of a scavenger. The literature of the American Vanadium Company has said this many times. While Mr. Norris has made statements, none of the investigators have submitted proofs that vanadium of itself adds any beneficial properties to steel. Professor J. O. Arnold, who is quoted by Mr. Norris, has not made any definite and positive statement to that effect. All of his statements are qualified with a word of doubt and thus show that until more complete data has been submitted he is not willing to make any positive statements. When Mr. Norris says, "It seems to have not only a chemical but a physical influence in promoting the even distribution of the carbon and retarding constitutional segregation," it does not necessarily mean what Mr. Norris wants it to mean.

By acting as a scavenger to remove the oxygen and nitrogen and thus prevent the formation of oxides and nitrides it would retard the segregation of the other elements in steel and cause a more even distribution of the carbon. It would also prevent the occlusion of gases to a large extent as well as the formation of phosphides and sulphides. In removing the above two gases it prevents other elements from forming combinations that are harmful to steel. It thus overcomes brittleness, refines the grain and makes the metal more homogeneous. This would cause it to have a greater resistance to rotary or vibrational strains, impact blows, or torsion as well as have higher static strengths.

The mere statement that a large number of steel manufacturers are producing vanadium steels regularly proves nothing except that they are supplying a demand.

Mr. Norris attempts an argument against my statement that various tests have shown that vanadium-treated steels cannot take the place of chrome-nickel steel. Again, however, absolutely no evidence, facts or data have been submitted. Countless tests have been made with vanadium-treated steels in comparison with other steels, but not one of these tests has shown us that vanadium treated steels equal either the static or dynamic properties of chrome-nickel steel; in most cases they could not nearly approach it.

The electric furnace for manufacturing steel is yet being experimented with in all kinds of ways. They are also producing all kinds of steel with them. Because some of these are vanadium-treated steels does not necessarily mean that the impurities removed by vanadium cannot be removed by using correct methods and slags in the electric furnace. If Mr. Norris had submitted any data to prove that vanadium-treated electric furnace steel is any better than electric furnace steels made without vanadium we might be inclined to listen and look for further data along this line.

As this argument is on vanadium, I will only say of the nickel-chrome steel that I called one of the best grades that it has been used by two engineers that I know of for the most vital parts of the automobile and gave better results than they obtained from other steel.

The widespread use of vanadium steels for numerous parts mentioned by Mr. Norris in his next to the last paragraph absolutely does not prove that "vanadium of itself adds any virtues to steel." It could just as readily prove that vanadium has fulfilled its mission when it has removed impurities and gone off into the slag, and thus strengthened and improved other properties of steel. Titanium, which in the ferro form is about one-twentieth of the cost of vanadium, has as great an affinity for oxygen and a greater affinity for nitrogen, it being the only undisputed example of the combustion of an element in nitrogen. This element will therefore give us practically the same results that are obtained with vanadium, and its growing competition may be the cause for the claims that vanadium of itself, in the proper percentages, adds to the static and dynamic properties of steels.

Neither in my original article nor in this answer to Mr. Norris have I said that vanadium did not produce beneficial results in iron or steel when properly alloyed and used in the correct percentages. The injurious effects of oxygen and nitrogen have been much more clearly brought to our attention since the advent of vanadium and much valuable data is thus at hand. That titanium or other elements still in the experimental stage or even the electric furnace will give us just as good results by removing the impurities is fast being demonstrated. As these are cheaper than vanadium they may take its place in steel making and leave to vanadium the medicinal mission claimed for it.

To satisfy Mr. Norris's curiosity, I will say that I do not think it possible to reduce sulphur and phosphorus by the crucible process to lower percentages than can be done in an open-hearth furnace. The possibilities of the open-hearth furnace are very great. By using the proper methods or slags it is possible to reduce sulphur and phosphorus to mere traces in an open-hearth furnace. This, however, costs money and makes the steel expensive. It is not possible to reduce these elements in the crucible, but the materials charged into the crucible must be such as will make their percentages low when the steel is poured into ingots. Ignoring possibilities, therefore, the probabilities are that when we buy commercial steels the crucible product will be lower in phosphorus and sulphur than the open-hearth product, as by charging the proper materials the phosphorus and sulphur are reduced to lower percentages in the crucible than in the open-hearth process.

Energy Diagrams and Efficiency

Showing How Available Energy Is Dissipated

Gasoline as it is poured into the tank of an automobile inherently contains a certain amount of energy and it is proposed in this article, that originally appeared in La Vie Automobile, to show how energy is lost through different channels before it arrives at the road wheels. It is suggested that makers should state the power of the motor as one unit and the power available at the road wheels as the other, thereby informing buyers as to what they are purchasing.

THE title of this article may appear complex to some, but in reality it is a simple question and, besides, is one that should interest the majority of car owners.

Every one knows what is meant by efficiency of a car; but as the word "efficiency" may have been used in other connections it is as well to be specific. If one were to put 10 liters (17.598 pints) of gasoline into the tank (weighing 0.7 kilogrammes to the liter) and possessing 10,000 calories (mean value), one would have for nourishment of the motor $10 \times 0.7 \times 10{,}000$ calories.*

It is possible to transform these calories into work in the form of kilogrammeters. (There are 7,233 foot-pounds in one kilogrammeter, one calorie equals 425 kilogrammeters, or 3,968 British thermal units, and one British thermal unit is equivalent to 778 foot-pounds.)

If the motor produces 75 kilogrammeters in one second it is said to have a power equivalent to one cheval-vapeur (which is equivalent to .9863 horsepower). To be exact, one horsepower is equivalent to 75.9 kilogrammeters per second.

With the 77,000 calories thus furnished to the motor we would be able to obtain, if the transformation was integral without loss, $77{,}000 \times 425$ kilogrammeters 32,725,000 kilogrammeters.

The ten liters of gasoline consumed in one hour would therefore give

$$\frac{32{,}725{,}000}{3{,}600 \times 75} = \text{cheval-vapeur}.$$

This is far from being correct because a 12-horsepower motor running at maximum power would not consume more than 10 liters per hour and (because it would be able to do at least 150 per hour) 6.6 per hundred kilometers. It is necessary to multiply by about 10 to approximate the actual consumption of such a car, as, for example, 66 liters. This consumption of 10 liters per hour and at full power corresponds rather to 12 horsepower than to 120 horsepower.

Therefore, instead of obtaining 121 horsepower at the road wheels at the point of contact with the road surface, this amount is nearer to 12 horsepower, *i. e.,* 10 per cent. That is to say, that a car that only gives 10 per cent. of the amount furnished is said to have a 10 per cent. efficiency. It is quite small, but, as is found out in practice, this is about the average. Certain cars could go as high as 15 per cent. (in which case they would have to furnish 18 horsepower), but this is a point rarely attained.

Where Does this Wasted Energy Go?

The motor for a start wastes a considerable amount. It only furnishes one-third of what one would be able to obtain on the crankshaft, as, for example, in the case of a dynamo. But in the transformation of energy from the clutch to the rims of the rear wheels there is a large proportion lost in transit. It is possible to measure these losses on the test bench by certain convenient apparatus. One can determine to which part to attribute the waste of energy—a liquidation so to speak—be it the motor, transmission, wheels or tires, and so on.

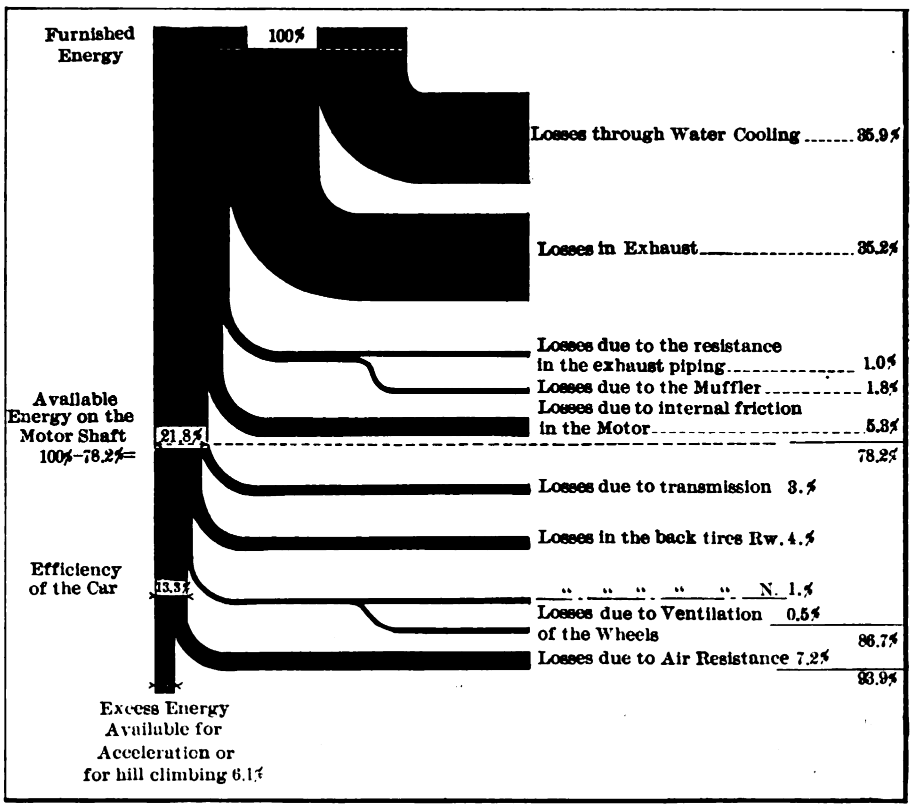


Fig. 1—Energy diagram of a 30-horsepower car running at 37 miles an hour (60 kilometers) on a level road, and the way the energy delivered by the gasoline is dissipated. The available energy at the crankshaft is only 21.8 per cent. of the total energy furnished. The motor and transmission comprising the wheels absorb 86.7 per cent. of the total energy, leaving 13.3 per cent. to combat the air resistance, grades and acceleration efforts; at 37 miles per hour 7.2 per cent. is absorbed in air resistance, leaving 6.1 per cent. for grade resistance. This surplus is totally absorbed on a grade of 6 per cent.

*Calories—Any of several heat units. The amount of heat required to raise the temperature of one gram of water one degree centigrade; called specifically small calorie. Since the specific heat of water varies slightly with the temperature, the rise of one degree is sometimes specified to be from 0 degree to 1 degree, or at or near 4 degrees (the temperature of the greatest density) or from 15 degrees to 16 degrees. In this last case the value of the unit is almost exacfly that of the mean calorie. The amount of heat required to raise one kilogram of water one degree centigrade. 1000 small calories, called specifically large or great calories. 1 calorie = 3,968 British thermal units. The amount of heat required to raise one gram of water from 0 degree to 100 degrees centigrade is known as centuple or rational calorie. One-hundredth of the centuple calorie is called mean calorie.

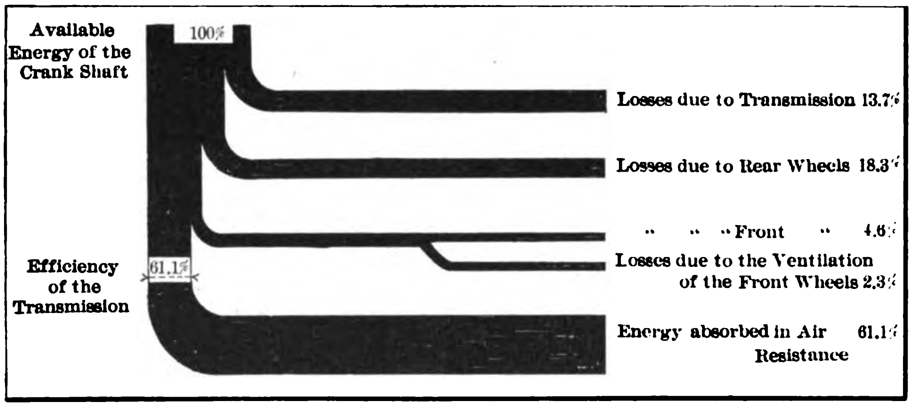

Fig. 2—Energy diagram of a car taking into consideration the amount of energy available at the crankshaft. The motor is driving the car at 69 kilometers (43 miles) per hour. All surplus power is absorbed by wind resistance

These partial results can be calculated and expressed in energy diagrams. An energy diagram is one that appeals to the senses; they can be constructed in various methods. In Fig. 1 is shown a simple one.

As the term liquidation has been used above it will be as well to continue the simile, which is a convenient one, and let it represent the energy in a liquid form that would flow from the motor to the rear wheels. En route there are tributaries by which some part escapes.

Fig. 1 represents the diagram of energy of a car traveling at 60 kilometers per hour with the motor working at full power. Of the 100 per cent. of energy furnished 78.2 per cent. is lost in the water cooling, through the exhaust manifold and on account of the frictional losses in the motor.

All that is left of the total energy that will be available at the crankshaft will be 21.8 per cent. If one were able to utilize the available energy at this point the conditions would be ideal, but this energy must be transmitted to the driving wheels, and in this undertaking some more is lost, for example, 3 per cent. in the transmission proper (there are numerous channels through which it can flow, such as gearing, frictional losses, etc.). On arriving at the wheels 0.5 per cent. is taken off in the ventilation of the wheel; that is to say, 0.5 per cent. of the primary energy furnished is utilized in overcoming the work of the ventilation of the spokes of the wheels.

Lastly the tires absorb a goodly proportion of what is left, the rear wheel tires pre-empting 4 per cent. and the front tires 1 per cent. Finally there is left at the point of contact of the wheels and the road surface 13.3 per cent. of the primitive energy, of which a little more than half, 7.2 per cent., is absorbed by the resistance of the air—that is to say, the work of penetration of the car through the air—and there remains 6.1 per cent., which it is not proposed to use at the present moment, but which will permit us to slightly increase the speed (in this example to bring it up to 69 kilometers per hour) or to overcome the resistance of a slight gradient.

Division of Power

Taking up the example of the car consuming 10 liters of gasoline per hour, we have seen that if the 100 per cent. of energy thus furnished were delivered in the form of work we would be able to make use of fully 121 horsepower.

If the diagram of energy shown in Fig. 1 were applied to this motor the 121 horsepower would be split up in the following manner showing how the available power is absorbed at the various points.

Available power on the crankshaft..........	26.378	horsepower
Available power at the rims................	15.093	"
Absorbed by air resistance..................	8.712	"
Available for acceleration and gradients....	7.381	"
The wheels and tires alone absorb......rear	4.84	"
front	1.815	"

From this tabulation an idea of the efficiency of a car can be obtained. It is these two characteristics, viz., power available at the crankshaft and power available at the rear wheels that first started the use of appellations of car such as 10-14, 20-24, 15-20, 30-40 horsepower, etc. In the following example we will call this car a 15-25 horsepower, and this designation will be quite rational. The buyer who purchases a 15-25 horsepower car will know just what he is buying. But numerous abuses have robbed this designation of all value. One usually understands what is meant when a firm calls their car a 14-20 or a 30-40, but it is possible that some would not understand what was meant by 8-80 horsepower.

It would be very simple to approximately gauge the available power at the rim, which can be measured on a testing apparatus such as that used at the Automobile Club. As cars are for the most part constructed in series it would be sufficient if the maker were to submit one model of the series for a test which would neither be very costly or long and in this manner one of the vexatious questions would be settled.

The diagram has been plotted to show the commercial or normal speed of the car and not the maximum speed. This commercial speed is the one in which the efficiency of the car is found at its best. If the diagram had been plotted for the maximum speed we would have one similar to that shown in Fig. 2, in which the starting of 100 per cent. has been chosen as the available energy at the crankshaft and not furnished energy. Fig. 3 represents a diagram of a car climbing a grade at 60 kilometers per hour. The resistance of the air and the resistance due to the grade absorb practically all the energy available at the rim.

These diagrams are interesting because they permit one to compare the different degrees of absorption and the quality of different cars. The point that is of interest to the purchaser and the maker alike is the amount of energy available at the rims of the wheels. When this characteristic is known it will be an easy matter to work out the ratio of gearing that would offer the best results. It is easy, as a matter of fact, to roughly approximate the energy that is absorbed by the air resistance at different speeds of running when the windage area is known. With these data to work upon one would know how much reserve power there is

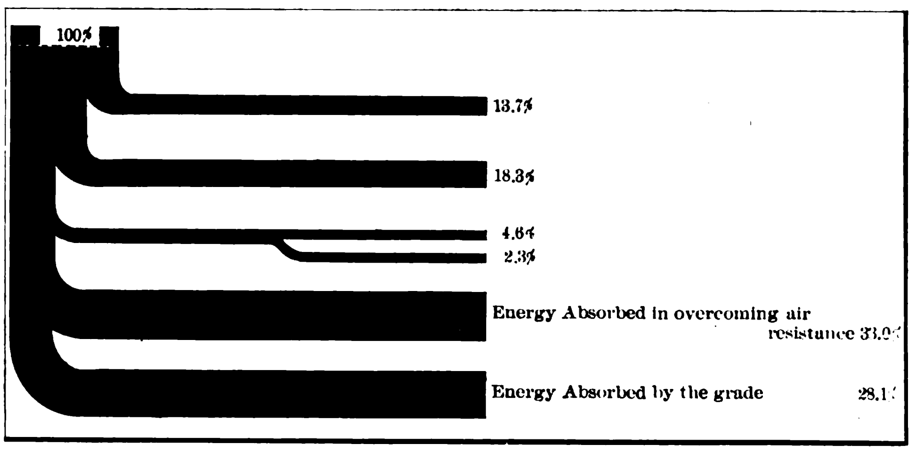

Fig. 3—Energy diagram of a 30-horsepower car running at 60 kilometers (37 miles) per hour, or on a grade of 6 per cent. (relating to the energy available at the crankshaft); 33 per cent. of this energy is absorbed in wind resistance and 28 per cent. by the resistance of the grade

available for accelerations of the car and grades on the different speeds.

If one wants a car that will climb hills easily even when heavily loaded, and without changing speed, a sufficient amount of reserve power must always be available. The more the reserve power one has the more pleasant it will be to drive the car, the quicker will be the starting qualities and the easier it will climb small hills.

On the contrary, if the excess power is small the driver will be forced to continually play with his levers and pedals. In the example chosen the car has a windage area of 2 square meters (21 square feet). If it were stripped for racing and the resistance were reduced to 1 square meter (10.764 square feet) the excess power would be much greater at 60 kilometers (37 miles) per hour—viz., 9.7 per cent. instead of 6.1 per cent, and with the same weight, 1.800 kilogrammes, the car would be able to climb a much stiffer hill.

How Steering Gears are Assembled and "Run In"

THE steering of some cars is particularly soft and easy of operation, which is due to proper balance and a good fit of all the parts, whereas the driving of another car, instead of being a pleasure, becomes a feat of muscular endurance. No doubt in time some of the stiffness will wear off, but high spots should be carefully removed before the car is handed over to the purchaser. The following method is the one employed in the Packard factory:

The throttle operating parts which are on the steering post are first assembled as a separate unit—the rod that goes inside the post, with the sleeve, collar and rocker arm at the lower end and the worm, throttle nut, lever, etc., at the upper end.

The steering worm and its shaft (which are one piece) are case-hardened and ground, then brazed into the post, and the bearing surfaces again ground. This and the steering wheel are the only composite parts that reach the assembling room out of the 184 different pieces that enter into the post construction.

A temporary steering wheel W is attached for "working in" the post, so that the permanent wheel may not be marred or soiled. The post is covered with a leather gaiter G for protection.

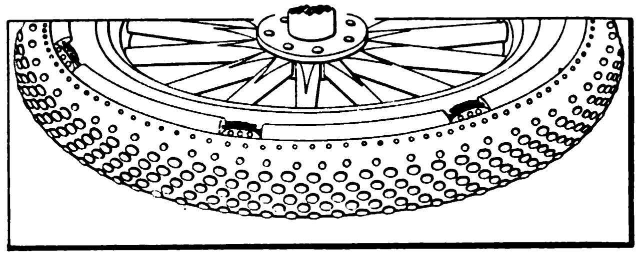
When the assembly is complete it is bolted to a solid rigging B on the floor, and first tested for any "play." Play cannot always be detected by manipulating the wheel with the socket in a vise. If play is detected, the post goes back to the bench and is readjusted.

With the post again bolted to the floor rigging, the sector lever A is attached by the steering connecting rod R to a hydraulic apparatus which imposes the same strains or conditions that are met with in road service with the car loaded. The expert takes it in hand, and by manipulating the different valves V in the test machine he gets the effect of driving over bumps and "thank-you-ma'ams" in a road, straight ahead and around the curves.

The steering-gear valve is operated by the backward and forward motion of the water pump and as the connecting rod R is attached by a ball socket to the piston rod, which latter is guided in the bearings B and B2, the steering is allowed to run itself in and thereby take off any high spots.

Center-Studded Detachable Non-Skid Treads

SUPPLEMENTAL treads on tires are now widely used, and there is more than one point to be said in favor of them; among others, that these treads offer the possibility of using a non-skid tread when it is deemed advisable to do so and which tread may be removed whenever the driver wishes. The protection afforded to the tire by the use of a well-fitting cover is a fact not to be decried, and it is generally in the small details that the various makes of detachable treads differ. In the selection of such treads, buyers lay most stress upon the possibility of quick adjustment and of maintaining tightness against the face of the outer tire shoe, which are indeed matters of considerable importance, especially the latter one; since the shoe will necessarily heat up if the outer tread slips on it, in which case the tire will suffer more than if it were running on the road itself.

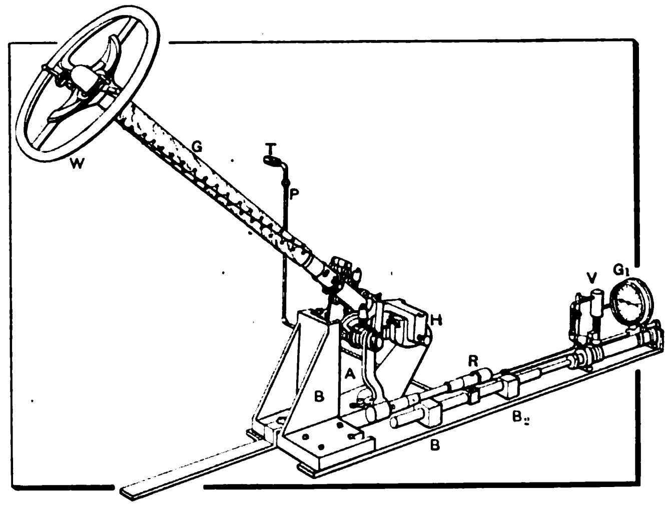


Illustrating the center-studded Woodworth tread

As an example of a non-skid detachable tread the Woodworth is shown in the illustration, it being the product of the Leather Tire Goods Company, of Niagara Falls, N. Y., and it will be well to call attention to the fact that the steel non-skid studs are only in the center portion of the tread, this being the part where it comes in contact with the road and which has to stand the continued working strain. The studs, as may be seen from the wax engraving, are set in several parallel rows, thus insuring prompt anti-skid action.

The illustration also shows the manner of fastening the tread to the tire. On both edges of the tread rings are provided which are composed of coil springs, of which there are six or eight. They are connected up by hooks and links in the manner seen in the cut, and a special tool is delivered to the buyer of every set, which permits of connecting up two springs by a single motion. This arrangement warrants tightness of the tread against the tire, and easy and rapid adjustment and detachment of the tread.

The center-studded tread has been designed with a special view to city work in which good roads only have to be encountered, generally speaking, in which cases, therefore, the protection of the central portions of the tire will fill all requirements. Owing to its character, the tread protects the tire against blowouts and punctures and, except when the car runs at very high speeds, the center-studded tread will be found very efficacious. In fact, if it is made to serve under the conditions it is intended for, it will be just as good as a full-studded tire, with the obvious advantages of less weight and price owing to its method of manufacture.



Showing the operation of running Packard steering gear

What Some Subscribers Want to Kno

Wants Information About Strange Motor

Editor THE AUTOMOBILE:

[2,754]—The other day I was examining a motor which seemed to be of the two-cylinder type with the cylinders cast en bloc. I was under the impression that it was an extraordinarily large diametered motor and on inquiring found that it was a four-cylinder motor with the cylinders alongside of each other. Will you kindly show me by means of a diagram how these cylinders are placed? CHAS. STEVENS.

Davenport, Iowa.

The motor described by you is shown in section in Fig. 1. Referring to the cut, it is seen that the cylinders are inclined to form a V-shape with each pair of connecting rods working on the same crank. There are three flywheels within the motor which are connected to the cranks and crankshaft in the manner shown in the longitudinal section through the motor.

Desires to Paint His Own Automobile

Editor THE AUTOMOBILE:

[2,755]—I have a 1906 Model, 5-passenger touring car, with a white body. I wish to paint it black myself, with the running parts and wheels straw. Please give me directions or refer me to some firm who will furnish materials and directions. SUBSCRIBER.

Midnight, Miss.

If the surface of the car body is in good condition, that is, free from checks and fissures, it should be thoroughly sandpapered, after cleaning off all oil and grease spots, with No. 1 sandpaper, and coated solidly with a coat of ivory black, japan ground, and thinned to a brushing consistency with six parts turpentine and one of raw linseed oil. Let this coat dry overnight and then rub the surface down lightly with fine curled hair, which may be obtained from any local upholsterer or carriage trimmer. Then dust off and apply a second coat of ivory black thinned in eight parts of turpentine and one part of raw linseed oil. For applying this thin color use for a touring car surface a 2 1-2-inch camel's hair double thick brush. Put this second coat of color on, say in the morning, and during the afternoon apply a coat of black varnish color. This varnish color may be shop-mixed by first thinning with turpentine and then adding sufficient elastic rubbing varnish to produce a sharp luster. The proportions should be 1-4 pound of color to 2 1-2 pounds of varnish. Preferably, however, this varnish color may be bought in the form of black rubbing varnish direct from the manufacturer. Apply the varnish color with a half-elastic bristle brush, flat width 2 1-2 inches. Let this coat stand two days, whereupon rub lightly with a piece of

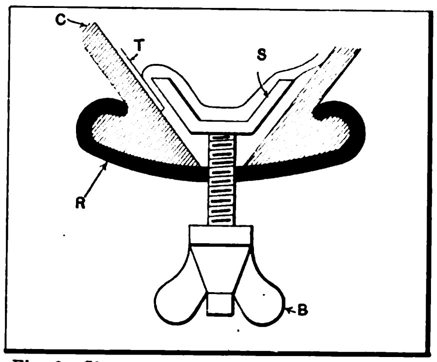


Fig. 2—Showing how tube is pinched by security bolt not brought properly into position. B, bolt; C, casing; T, tube; R, rim; S, security bolt

broadcloth dipped in water and pulverized pumice stone. Wash and clean the surface thoroughly and apply a coat of elastic rubbing varnish, to which should be added a teaspoonful of ivory black to each pint of varnish.

This black counteracts the discoloring properties of the varnish. Permit this coat to stand 4 or 5 days, the longer the better, then with a perforated piece of 1-2-inch felt dipped in water and then in the pulverized pumice stone rub the surface very thoroughly and uniformly, wash up and apply the necessary lines of striping. When these are dry, apply a coat of the clear elastic rubbing varnish, and after another four days rub with water and pumice stone, as above advised, wash up and finish with a high-grade finishing varnish. For a cheaper job omit one coat of the rubbing varnish and for a quicker schedule, use quick-drying rubbing varnish.

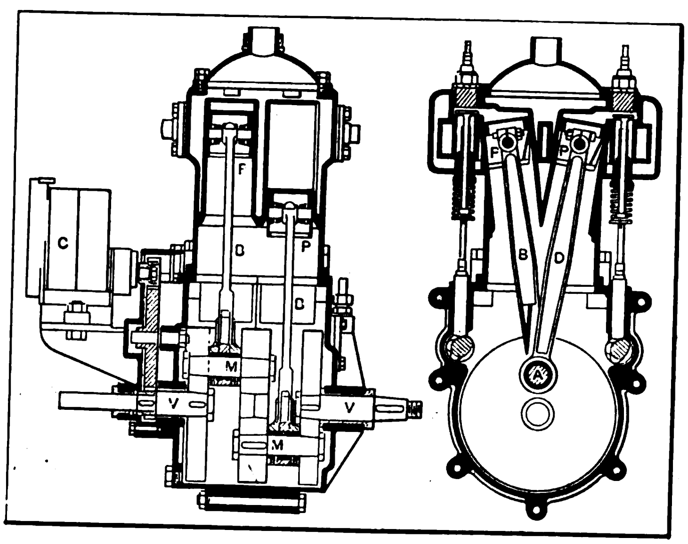

Fig. 1—Sections through a four-cylinder en bloc, V motor, showing a longitudinal and transverse section with the pistons, piston rods and three flywheels in their relative positions. P, piston; B, connecting rod; M, crank-pin; V, crank shaft; C, magneto; A, section of crank-pin

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their automobile troubles, stating them briefly, on one side of the paper only, giving as clear a diagnosis as possible in each case, and a sketch, even though it may be rough, for the purpose of aiding the Editor to understand the nature of the difficulty. Each letter will be answered in these columns in the order of its receipt. The name and address of the subscriber must be given, as evidence of good faith.

If the body surface is checked and fissured to a considerable extent sandpaper the surface after cleaning up, and apply a coat of lead-colored pigment darkened to a slate color and made of oil, ground white keg lead and lampblack, and containing enough oil after thinning with turpentine to bind the coat securely to the white foundation. Putty all defects in this surface very carefully, and proceed with the color coats as already detailed.

For the chassis or running parts, if the surface is in good condition the straw color may be applied directly upon the white, which color, by the way, makes an ideal background for straw. The straw color may be procured of any first class color grinder or it may be mixed in the shop of 5 parts of arctic or flake white, 2 parts lemon yellow and a drop or two of English vermilion. Use the japan ground yellow and white in making the straw color, and thin out with turpentine and raw linseed oil in the proportions advised for the color coats on the body. Apply two coats of the flat yellow on the chassis and then one coat of yellow varnish color, rub lightly on this coat with water and pulverized pumice stone, stripe in single, double or three lines as preferred, apply a coat of quick or medium-drying rubbing varnish and in due time rub down as before and finish with a good grade of chassis varnish. For a cheaper job omit the rubbing coat of varnish.

To Prevent Tire Pinching

Editor THE AUTOMOBILE:

[2,756]—Having recently purchased a car and seeing that you are kind enough to give advice to beginners through the correspondence columns of your paper, I take the liberty of asking you to help me. I have mastered the mechanical parts of the car fairly well, but the tires cause me great anxiety. I do not drive fast, which I understand is the greatest source of tire

Vhat Other Subscribers Have to Say

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their personal experiences for publication in these columns for the worthy purpose of aiding brother automobilists who may be in need of just the information that this process will afford. Communications should be brief, on one side of the paper only, and clearly put, including a rough sketch when it is possible to do so, and the name and address of the writer should be given as evidence of good faith.

trouble, but the tubes get pinched and nipped and I would like to know the reason for this. I pay particular attention when fitting a new tube not to let the lever come into contact with it. I should be obliged if you would give me a suggestion as to how to overcome this trouble. READER.

New York City.

Your trouble may be caused either by the security belt or the bead on the casing. The tube T shown in Fig. 2 has been imprisoned by the security bolt S so that the latter cannot seat properly the bead. Or, when the car is turning a corner and the tire is not sufficiently inflated, the bead lifts from the rim R and pinches the tube T between the rim and the bead in the manner shown in Fig 3. Before attempting to replace the outer bead of the casing into the rim inflate the tube slightly and pass the hand inside the casing so as to be sure that the tube is not twisted or held under the security bolts. After the casing has been replaced the security bolts should be pushed up and down several times in order to make sure that they are free and seat properly.

Starting with a Broken Crank

Editor THE AUTOMOBILE:

[2,757]—Would you kindly inform me through your columns of a method of starting a motor which has a broken crank. The crank is broken in such a way that it is impossible to use it and the machine was towed to a repairman. I would like to know if it would have been possible to start the engine without the crank? A. P. V.

Albany, N. Y.

If the flywheel is accessible it may be turned over and the engine started. When doing this it is well to prime the cylinders through the pet-cocks. A rear wheel may be jacked up and turned over in a forward direction with the high gear thrown in. Still another way is to let the car run down hill or get some one to push it with the clutch disengaged until it gains momentum, the clutch is then thrown in. When the explosion occurs the clutch is disengaged until the motor gains speed.

Interested In Sleeve-Valve Motors

Editor THE AUTOMOBILE:

[2,758]—I take the liberty of asking a question and would be pleased if you will give me a reply at an early date through the columns of your paper. On page 1056 of the issue of your magazine for December 22, 1910, you describe the Henriod four-cylinder rotary valve motor. Will you please explain by a sectional view of this motor the operation of the rotary valve, and also the auxiliary piston in the Berliet motor referred to in the next paragraph.

Detroit, Mich. K. C. W.

The Henriod type of rotary valve is illustrated and described in another portion of this issue, and the Berliet auxiliary piston will be described at a later date in the near future.

Wants Information on Marine Motor Design

Editor THE AUTOMOBILE:

[2,759]—Will you kindly give me the following information through your columns:

1. What should be the relative volume of the compression space in a 10 x 10-inch gasoline motor for best and most economical working; or, in other words, what percentage of the volume should be left when the piston is at the highest point of the stroke?

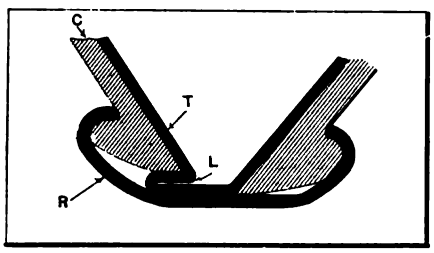

Fig. 3—Showing soft tire pinched by casing. C, casing; T, tube; R, rim; L, lap

2. I have an 8-cylinder 10 x 10-in. motor on a launch and am greatly troubled by premature firing. I believe high compression to be the cause. Do you think so?

3. What should be the length of stroke of a low-speed marine motor of this bore according to modern ideas? C. MORRIS.

St. Louis, Mo.

1. For a compression of about 65 pounds, the total volume of the cylinder would be about 3 1-2 times the clearance volume.

2. High compression is one of the causes of pre-ignition, but it is infrequent in a well-designed motor. For a slow-speed marine motor a compression of 65 pounds would be ample. To determine the amount of compression the spark plug should be removed and a bushing inserted; a pressure gauge can then be attached. The engine may then be turned up against compression and readings taken on the gauge.

3. A very flexible motor for marine work would be given by having a bore of 10 inches and a stroke of 13 inches.

Compressing Spring on Clutch

Editor THE AUTOMOBILE:

[2,760]—I have removed the clutch from my machine and find that I cannot compress the spring. I would like to know of a method of compressing the spring, perhaps by means of some simple fitting which I will be able to attach myself, and if you could give me any advice on the same in your columns I am sure it would be of general interest. SUBSCRIBER.

Grand Rapids, Mich.

A simple attachment which can be made in any shop, or by a blacksmith, is shown in Fig. 4. Around the collar of the clutch is placed a split clamp held together by two cross bolts. Passing through this clamp are two bolts about 3-8 of an inch in diameter sufficiently long so that the cross piece which is seen in the illustration touching the clutch spring, and which has two holes drilled in it, can pass over the bolts and allow sufficient room on the threads to start the nuts. With the aid of a wrench, the nuts can be alternately tightened until the spigot shaft passes sufficiently far outside the spring to permit the adjusting collar and nut to be screwed thereon.

The cross piece has to be drilled so that the shaft will pass through easily and sufficient to allow the nut to pass.

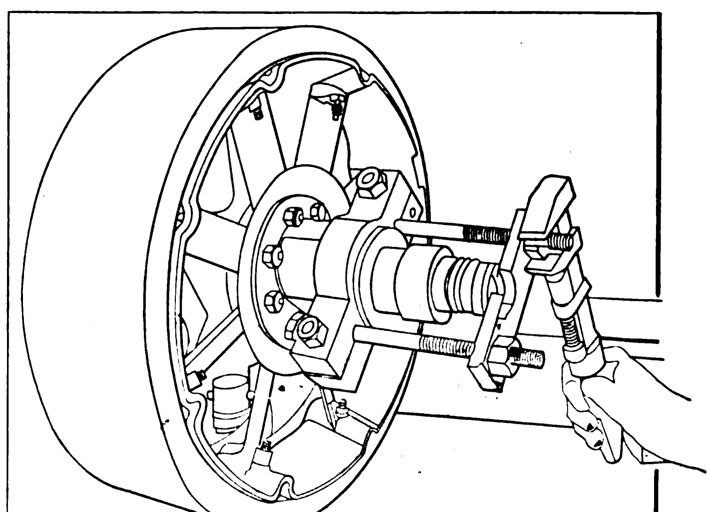

Fig. 4—Showing the method and tools used in compressing the clutch spring

Meeting Recurring Troubles

Presenting a Series of the Most Probable Cases

A series of correlated short stories, accompanied by diagrams and characteristic illustrations, including the nature of the troubles that are most likely to happen to automobiles, discussing their causes and effects, all for the purpose of arriving at a remedy. It is the aim for the most part to show how these troubles may be permanently remedied, and as a secondary enterprise it is indicated how the automobilist can make a temporary repair, thereby enabling him to defer the making of a permanent repair until a convenient time arrives.

Automatic Lubrication on the Panhard & Levassor.—The lubrication of the Panhard & Levassor twenty-horsepower valveless motor is done by means of both pump and splash. The oil is contained in the crankcase, which has a capacity of about 2 quarts when the oil is up to its proper working level. The oil is supplied to the crankcase by means of the breather pipes, which are equipped with strainers to insure a clean supply of oil to the crankcase.

The pump, which is driven off the camshaft, is of the plunger type and has a variable speed, which is entirely dependent upon the speed of the motor. The quantity of oil delivered, however, may be regulated by adjusting the length of the stroke of the pump plunger. The pump lifts the oil from the crankcase and forces it up through a sightfeed, which is located on the dash. After passing through the sightfeed the oil flows down into the splash troughs, which are located under each cylinder. In passing to these troughs the oil is led through the main bearings of the crankshaft and in this manner their lubrication is made positive. Another means of adjusting the quantity of oil supplied to the motor is furnished in the sightfeed itself, as the quantity of oil which passes through it may be governed and the excess will pass through a by-pass and back into the oil tank under the foot boards of the motor. The oil tank is connected directly to the pump by means of the suction pipe through which the oil is drawn on the first stroke of the pump. On the second stroke of the compound pump the oil is sent to the sight-feed.

After having passed into the splash troughs the oil will be picked up by the connecting rods and dashed into a spray. In case an excess of oil collects in the crankcase due to too much having been admitted from the sightfeeds it will be necessary to drain the excess from the base of the motor. For this purpose a drain, which may be opened by pulling a wire on the dash, has been installed. It is thus possible for a driver to drain the excess oil from the crankcase without leaving his seat.

There is a lead into the gear box which takes care of this part of the mechanism, while the transmission and differentials are taken care of independently by being packed in oil and grease.

Lubrication of the 25-h.p. Paige-Detroit.—The Paige-Detroit car is lubricated by a simple splash system. The lower half of the crankcase is divided into two parts, the lower part forming the oil reservoir, while the upper carries the oil being used for the splash system.

The upper division of the oil pan casting is moulded so as to contain a series of troughs, one below each cylinder. These troughs are deep enough to hold the oil into which the connecting rods dip at each revolution.

The oil is drawn from the lowest part of the crankcase by a plunger pump and forced through a sight-feed located on the dash. It then flows by gravity into the foremost splash chamber, drains over this into the next, and so to the last. When the oil level in the rear splash chamber becomes so high that it overflows the walls it passes down into the reservoir again. Then the oil is strained and passes again through the pump, which is driven off the camshaft.

The connecting rods dip into the troughs with such momentum that the oil is thrown in a spray up into the cylinders, lubricating their walls, as well as the connecting rod bearings and camshaft.

There are drain plugs in the bottom of the crankcase through which the oil may be drained out.

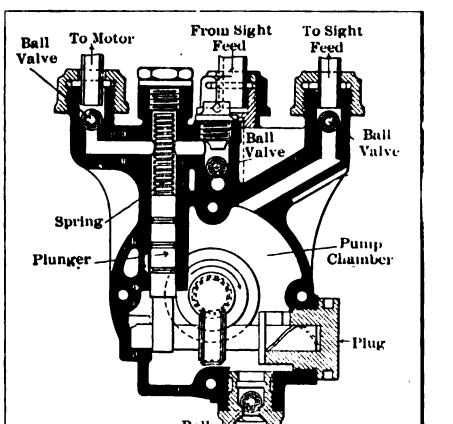

Fig. 1—Oil pump on Panhard & Levassor 20-horsepower valveless motor, showing leads, ball checks and plunger

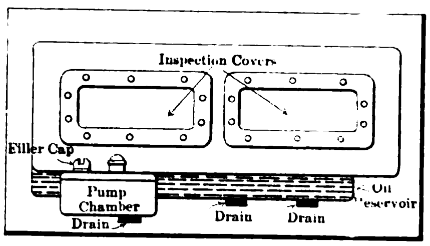

Fig. 2—Paige-Detroit crankcase, showing inspection covers on side of crankcase and location of oil reservoir

The Marion "40" Lubrication System.—The Marion 40-horsepower car is lubricated by a combination of the force-feed and the splash systems. The oil is forced by means of a pump to the main bearings. After passing through the main bearings and lubricating them, the oil drains down into the splash troughs, which are located in the crankcase in such a position that the connecting rods splash into the oil contained in them for a depth of about one-eighth of an inch.

The pump is located on the left-hand side of the motor. It is of the gear type and is driven off the camshaft. The pump draws its supply of oil from the crankcase reservoir, or, in case the oil level in this reservoir has fallen below the required amount, oil may be pumped to the pump chamber by means of a hand plunger pump which is located on the board just below the driver's seat.

The hand plunger pump draws the oil from an auxiliary tank in the rear of the car and forces it into the crankcase just under the pump chamber.

When about to start on a run the reservoir should always be filled to a fair level, the amount necessary of course, depending on the length of the trip. The level of the oil in the crankcase reservoir may be observed by means of a gauge glass, which is set between the two middle cylinders on the top of the crankcase. The oil level should never be allowed to sink out of sight in this glass.

When the oil tank requires filling the top of the breather tube is removed and the oil poured through the screened opening in the pipe. It is a good plan to clean the screen immediately after the oil has been poured into the tank.

The entire interior of the motor is oiled by the oil mist which is present in the crankcase due to the splash of the rapidly revolving cranks into the oil in the crankcase partitions. This oil will flow back to a certain extent into the reservoir from where it is again passed through the system. Besides the cylinder walls, connecting rod bearings, etc., the camshaft, timing gears and water pump shaft are also lubricated by the splash.

There are grease cups located at various parts of the car. The differentials are packed in light grease, as are also the transmission and wheel bearing casings.

Combination System of the Marion "30".—The crankcase of the Marion "30" is divided into four sections, which form the splash troughs for the auxiliary oiling system. The main oiling system is a mechanical force-feed arrangement which is located at the highest part of the engine on the rear end. The mechanical oiler box is filled through a filler opening in the front end of the box by removing a cap. There is a gauze screen in the opening through which the oil is poured into the box. Before filling the tank the screen should always be taken out and cleaned with a little gasolene.

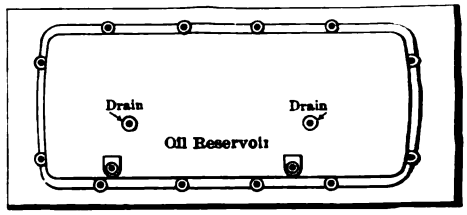

Fig. 3—Illustrating oil pan of the Marion "30," with drain plug and bolt holes shown

Besides the oil carried in the force-feed box there is a supply carried in the splash troughs in the crankcase. This part of the crankcase should be filled to the level of the top of the trough walls before starting on a trip, so that the cylinders will be lubricated by the splash as well as by the force-feed system.

The force-feed system is operated by an eccentric off the flywheel shaft. An eccentric rod runs from the eccentric up to a crank on the side of the oiler box nearest the dash. This crank drives a shaft which runs through the mechanical oiler and rests on a journal on the forward end of the box. There are three cams located on this shaft, each cam driving two oil pumps of the plunger type. The cams lift the pump plungers and allow them to fall suddenly over an edge of the cam. A spring attachment causes them to snap down; thus sending the oil, under pressure, down the six leads which are located beneath the box. Since there is a separate pump for each lead the amount of oil pasing through each may be regulated according to the needs of the spot to which the oil is led. This regulation is affected by means of adjustment screws on top of the box.

There are three main bearings, but only one of them is supplied by oil from the mechanical oiler; this being the one nearest the flywheel. The others are oiled by means of the splash system. Four of the leads from the oiler box run respectively to the walls of each cylinder, and the remaining lead runs into the timing gear case.

The excess oil from all the bearings supplied by the force-feed system drains into the crankcase. In this manner the troughs are kept constantly full.

The connecting rods dip into the oil for a distance of about one-eighth of an inch and churn the oil in the crankcase up into a fine vapor.

Circulating Scheme of Thomas Cars.—The Thomas cars are lubricated by means of a circulating system which takes the oil from the reservoir and sends it through the oiling system. After use the oil is strained and used over again.

The reservoir is located in the crankcase and holds about two gallons of oil. The crankcase is arranged so as to have an inner and an outer bottom. In the outer or lower bottom the oil is carried, while the inner bottom is divided by partitions so that a trough is formed below each cylinder. There are three standpipes of elliptical section, so placed that in case the oil rises high enough to overflow the trough walls it will drain into these standpipes and by means of them into the oil reservoir below. The function of the troughs is to hold a sufficient supply of oil for the connecting rod caps to dip therein and churn the oil up into a vapor.

The pump which actuates the circulating system is of the plunger type. It takes the oil from the lower part of the crankcase and sends it through a three-glass sight feed and the three leads to the main bearings. The sight feed is located on the dash, and by its aid an accurate account of all the oil passing through the system may be had as well as a knowledge of the condition of the pump. The pump is driven off the cam shaft by means of a vertical shaft, spiral gears and an eccentric. It is contained in a brass casing which is held to the bottom of the motor base by cap screws.

After lubricating the main bearings the oil finds its way down into the splash troughs, from which it is picked up by the connecting rods and carried

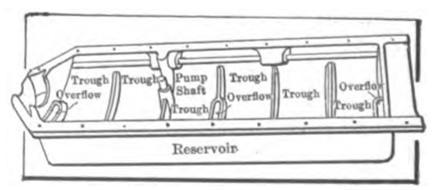

Fig. 4—Lower half of Thomas crankcase casting, illustrating disposal of splash troughs and overflow holes

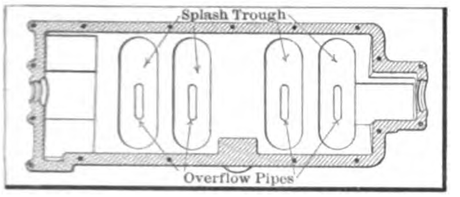

Fig. 5—Oil pan casting of Marion "40," showing overflow standpipes and oil troughs

to the other bearings. The oil through the standpipes drains back into the reservoir, but before entering into the suction end of the pump again, it passes through a strainer.

The reservoir is filled through the breather provided with a screen. The amount of oil present in the reservoir may be determined at any time by two try cocks provided for the purpose. The upper one is opened when filling the reservoir and oil is poured in until there is a flow of oil from it. The oil should never be allowed to run below the lower one. If it should reach the level of the lower try cock there is still enough oil in the tank for a run of about fifty miles, which will generally be enough to take the car to a place where more oil can be procured. The upper try cock is stamped FULL while the lower is stamped SAFETY.

The oil in this system should be thoroughly drained out about once a month and the crankcase flushed out with kerosene. To loosen carbon deposit the crankcase may be filled to the working level with kerosene and the motor run for about a minute in this condition. The other bearings throughout the car are taken care of by grease cups and oilers, while the differentials and transmission run in oil and grease.

Mechanical Oiler on the Stevens-Duryea.—Stevens-Duryea cars are equipped with a mechanical oiler placed on the right-hand side of the crankcase at about the longitudinal center of the motor. This mechanical oiler carries the oil supply as well as a set of pumps which actuate the force feed. The mechanical oiler box has a capacity of five quarts and may be refilled by lifting the right-hand part of the engine hood and unscrewing the cap over the filler hole, which is on the front end of the box. When the cap is removed a screen is exposed through which the oil is poured, thus removing any foreign matter present in the oil.

Within the mechanical oiler box, which is placed so that the heat of the exhaust keeps the oil in a state of uniform temperature and consistency, there is a mechanically operated independent pump for each one of the leads through which the oil is forced to the main bearings. The pumps are driven from the layshaft by means of gears which drive a shaft in the oiler box. The small plunger pumps are driven in turn from this shaft, and the stroke of their plungers may be regulated anywhere from 0 to a full stroke. In order to determine exactly how much oil is being delivered from each pump it is only necessary to press down upon the bleeder valve caps while the engine is running. Oil will then drop from the bleeder valve nozzle into the tank instead of through the lead to the main bearings as it will do when the pressure is relieved. The plungers should be adjusted so as to give about two drops on each downward stroke, although when the car is new a little more oil may be of advantage until the bearings are worn to a smooth fit.

After the oil is forced by the plunger pumps to the main bearings it will lubricate them and drain into the crankcase, which is divided so as to have a compartment below each cylinder. A pool of oil will be formed in the compartment into which the connecting rod will dip at each revolution, thereby lubricating the moving parts in the entire crankcase.

Within each crankcase compartment there is a standpipe 1 1-8 inches in height. The oil should never be allowed to be above the level of the top of these standpipes, for then the motor will commence to smoke; for this reason the pumps in the mechanical oiler should be so adjusted that they do not give too much oil. At the bottom of each standpipe there is a cock which may be opened to let the oil flow out should it have accumulated to a height which is above the level of the top of the standpipe. If oil does not flow, however, it is not by any means a danger sign, as the motor will be amply lubricated if the pumps are each feeding two drops of oil on each downward stroke. Oil may be supplied directly to the crankcase if

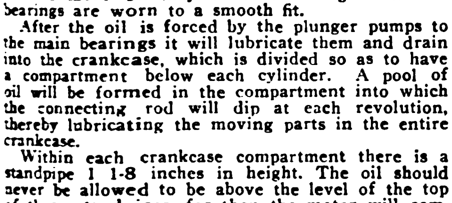

Fig. 6—Illustrating oil reservoir and drain and level cocks on Stevens-Duryea crankcase

necessary through the breather pipes. There are three of these, one to each pair of cylinders. They are equipped with screens.

About once a month the crankcase should be cleaned out with kerosene. This can be done by removing the petcocks under the base of the motor and filling to the usual level with kerosene oil. The motor is then started and allowed to run for about a half minute. The petcocks are then removed together with the drain plugs and the kerosene allowed to drain out. The plugs and cocks are then replaced, the latter being left open and oil is poured through the breathers until it starts to flow from the petcocks. The cocks are then shut off by turning the handles up.

The transmission case may be treated in the same manner, except that it is filled with about two quarts of heavy black cylinder oil.

Circulating Scheme on the Royal Tourist—The circulating system which is employed on the Royal Tourist motor is operated by means of a gear pump which is located in the reservoir which carries the oil supply. This reservoir is in the base of the motor and has a capacity of about two and one-half gallons. The pump is of the gear type and is driven off the camshaft. It takes the oil from the base of the motor and forces it up through a filter located on the side of the motor and easily accessible, so that the screens may be taken out and cleaned from time to time. The oil in the filter, which acts at the same time as a distributor, is under a pressure of about two pounds. The pressure in the filter and distributor may be easily determined by means of a pressure gauge which is located on the dash. Special care has been taken to perfect this filter, and it is constructed so as to be composed of alternate layers of filter paper and metal disks.

There are two leads from the filter, one of which passes directly to the timing gear case, and the other passes up to a sight feed, at which point the oil is divided into three parts and passes through three separate sight glasses. Each of these sight glasses leads directly into a lead to

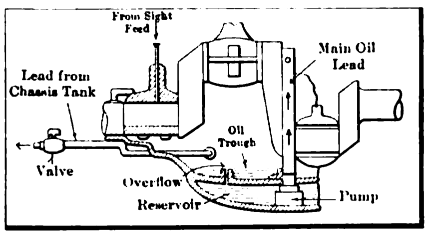

Fig. 7—Showing circulating system on Royal Tourist motor and the lead from auxiliary chassis tank

a main bearing. The main bearings are lubricated by the oil which passes through these leads, the oil then draining down into the splash troughs which are placed so that there is a trough below each cylinder.

The oil drains from the main bearings at a rate which is rapid enough to keep the troughs constantly full and overflowing. The overflow of the splash troughs is taken care of by a series of standpipes which are placed one in each trough. These standpipes are of such a height that when the oil reaches the top it is of just such a height that the connecting rods will dip to a proper depth into the oil contained therein. The rapidly revolving connecting rods churn the oil into a mist which entirely pervades the crankcase and lubricates all the moving parts which are located within the confines of this casting.

To make the lubrication more certain there is an oil catch on the crank cheek which catches the oil and by centrifugal force sends it through a lead drilled in the crankshaft up into the crank pin. The bearing at the crank-pin end of the connecting rod will be lubricated by the oil which flows through the duct in the pin, and in addition the oil is sent up along the connecting rod through a small tube to the wrist pin. With this system there is a forced feed to the three crankshaft bearings and to the bearings at the ends of the connecting rods.

Should the pressure at any time mount too high there is a safety valve controlled by a spring which allows the oil to by-pass into the timing gear case. The supply of oil through the main leads may be governed by means of this safety valve. To increase the supply of oil delivered to the main bearings, the nut which controlls the tension on the spring which holds the ball check in the safety valve is given a turn or two to the left, thus releasing the tension on the spring. To decrease the supply of oil the procedure is, of course, directly opposite.

Besides the supply of oil which is carried in the crankcase there is an auxiliary supply carried in a three-gallon chassis tank located under the floor boards. Between the tank and the lower part of the crankcase into which the pipe from the tank is led a valve is inserted so that the supply of oil in the crankcase may be augmented at will.

The other bearings on the car are taken care of in the usual manner by means of grease cups, while the transmission and differentials are packed in oil and grease.

Adjustable Troughs on the Daimler.—The Daimler cars are lubricated by the splash system. The oil reservoir, which has a capacity of about two gallons, is located in the lower part of the crankcase. The crankcase casting is in the form of a basin with an inner and an outer bottom. In the lower or outer bottom the oil supply is carried, while the inner bottom, which in this car is not an integral part of the crankcase casting, is an adjustable tray capable of a perpendicular motion. Upon this inner bottom or tray rest the splash troughs into which the oil flows while the lubricating system is in operation.

The oil starts originally from the bottom part of the crankcase in which the whole available supply of oil is carried, and passes up into the line of splash troughs and then overflows back to the reservoir in the bottom. This process of circulation requires of necessity some outside force to carry the oil through the system, and this is furnished by means of an oil pump. This pump is of the plunger type and is driven off the camshaft by means of an eccentric and rod, which extends vertically down into the base of the motor on the right-hand side, being enclosed, however, by the crankcase so that it is in itself lubricated by the splash of the connecting rods into the above-mentioned troughs.

The pump lifts the oil from the crankcase reservoir and forces it into the main oil lead, which is a pipe running around the inside of the crankcase. This pipe is perforated at the forward end of the crankcase so that it permits the oil to drop into the foremost trough. The oil is constantly being fed from the pump, so that it will soon overflow the first trough and find its way back until all the four troughs are completely filled and overflowing.

The connecting rods dip down into the oil and beat it into a mist which is present in all parts of the crankcase in sufficient quantities to lubricate all the moving parts therein. This includes the pistons, connecting rod bearings, camshaft bearings and the pump eccentric rods as well as all the crankshaft bearings. The pump, since it is operated from the camshaft, will bear a relative speed to the motor itself, that is, the greater the number of revolutions per minute made by the motor the greater the number of strokes per minute made by the pump plunger. This takes care of the speed of the car, but does not automatically take cognizance of the heavy duties laid upon the motor in moving slowly up a steep hill. To take care of this an arrangement is made whereby the connecting rods dip more deeply into the splash troughs and hence throw more oil up into the heated cylinders. A motor will have great tendency to heat up in running up a hill owing to the open throttle and late spark. In this way the mixture is not only rich, but the late spark tends also to overheat the motor. A rod, which runs longitudinally within the crankcase, is jointed to the tray which carries the splash troughs, so that when it is turned by means of the regulating levers the tray is lifted and in this manner the connecting rods are bound to get more oil. Besides acting as a lubricant, when the oil is copiously supplied, as it will be when adjusted in this manner, it also acts as a liberal cooling agent.

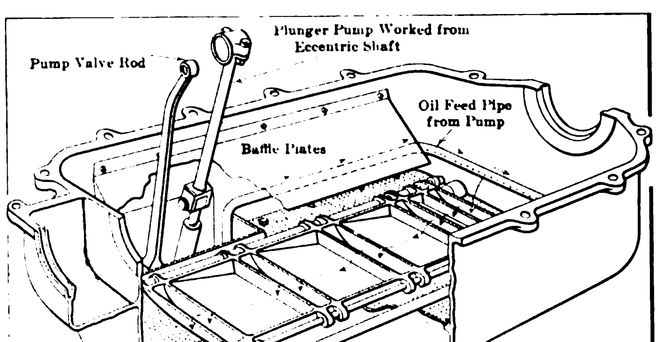

Fig. 8—Sectional view of adjustable splash gutters in use on English Daimler cars. The pump rods and eccentric are also shown

Making Wooden Chassis Frames

The making of the wood sill is an important operation in the plant of the H. H. Franklin Manufacturing Company, which features this form of construction, having used and developed it from the time it first began to build its air-cooled cars thirteen years ago.

Fig. 3—Screwing the laminations of the sill together

THE study of wood for the manufacture of sills and the results obtained have not attracted the widest attention in the automobile world, due to the fact that the majority of cars are built with steel rather than wood and that there are few wood chassis frames outside the line of the H. H. Franklin Mfg. Co.

The course of a piece of timber which is designed to become a part of one of these sills is hedged about with as much watchfulness as is that of a piece of high-grade steel. From the very beginning the wood is carefully chosen. It is all ash of second growth.

This is selected because it is of better grain than first growth and is more adapted to the service requiring strength, resiliency and lightness. Most of that used at present is taken from northern Pennsylvania. Southern ash is too brash. The stock is carefully selected. The second-growth ash used is about 16 feet long and is 1-inch stock.

After being shipped to the factory it is stored in a yard to season for two years after which time it is ready to be used.

When it has been thoroughly weather seasoned it is taken to the sawmill and, after being marked with a form, is sawed up into sill-shaped pieces. These are given a short kiln drying to increase their resiliency and render them less susceptible to weather conditions. From the kiln the pieces go to the wood shop where they are planed.

This operation is shown in Fig. 7.

Some are planed thinner than others, and the next move consists in sorting out two thick sections and one thin section, the latter being the middle ply of the three-lamination sill. The outer layers are left thicker at this point as yet more planing and trimming which in the end leaves the three laminations the same thickness. These three sections are painted with glue and are fastened together with clamps applied in close proximity to each other, the whole operation being clearly indicated in Fig. 2.

The gluing is generally done late in the afternoon, and the clamps are allowed to remain in position until the following morning, causing the glue to "set." Then after more jointing and planing the sill is marked, band-sawed and shaped on a former. This leaves it the size desired for use.

Being made of three layers of wood, precaution is taken lest water or the weather affect the serviceability of the pieces by working into the glued joints at the top and bottom. Along the top and bottom of each sill is fastened a strip of ash 3-16 of an inch thick. The three laminations are next fastened together with screws, making the three-ply sill stronger than it would be were it a whole piece of the same size. The thickness of the completed sill is 1 3-4 inches. The screwing operation is shown in Fig. 3.

To provide for the rear cross bar, the sills are put through a forming machine which cuts a right angle section from the rear end of each, permitting the insertion of the cross bar ends. Holes are next bored for the emergency brake band lever, and then the sill goes to its assembly.

Bench workmen, who perform this task, clean the sill and round up the top and bottom edges. The top corners are rounded with a radius of approximately 1-16 of an inch while the bottom corners are rounded with a radius of 1-8 of an inch. This is because the larger radius is more serviceable in its position while the 1-16 of an inch radius is more pleasing to the eye.

The front end of each sill is covered with an aluminum cap. The rear corners are strengthened by a block 4 x 4 x 4 1-2 inches, glued and screwed inside the angle.

In assembling the forms the work is carried on a "trestle." The floor boards, very small iron attachments, etc., are put in place here.

Workmen are not troubled with measuring for the location of holes, all this being done with a templet. In boring, certain positions of the frame on the "trestle" give the correct angle for the holes. The glue used in this work is an imported French sheet glue.

The length of sills for models H, D, M and G, is, respectively: 162 1-4 inches, 147 1-4 inches, 129 inches and 119 inches.

The rear ends of the sills are thicker vertically than are the front ends, although the difference is but a slight fraction of an inch. The thicknesses at the rear end for models H, D, M and G are respectively: 4 inches, 4 3-16 inches, 3 31-32 inches and 3 3-4 inches.

For these same models the measurements at the center of the sill, which point is thickest vertically, are 7 inches, 6 1-2 inches, 6 1-2 inches and 5 3-4 inches.

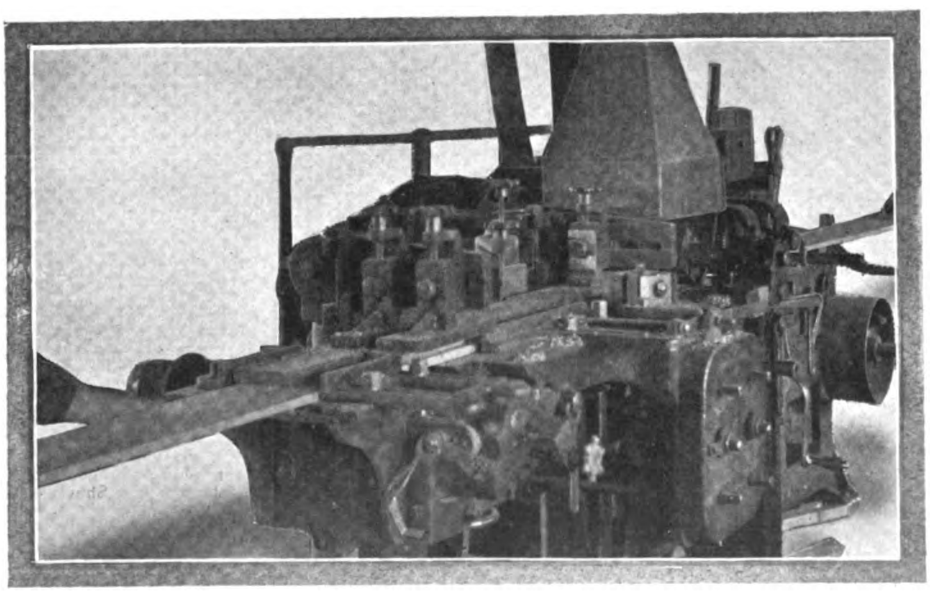

Fig. 1—Showing the process of planing the sill-shaped pieces after kiln-drying

The reason put forward for using a wood sill or frame on the Franklin cars is because it is stronger and lighter and also because its capacity for absorbing vibrations and road shocks is very much greater than that of steel. There are quite a few comparative uses for wood that are somewhat similar under certain conditions and which should be stated in arguing for the advantages of a wood sill. For instance, one of the greatest articles used in impact is the hammer, and all of these have wooden handles. If one were to put a steel handle in one of these hammers a great difference would be noticed in the effect on the human body of a blow.

Another very apt illustration is a steam hammer. Whereas a steam hammer of itself is set on a concrete foundation the anvils of practically all steam hammers used in steel mills and such places are set up on wooden foundations.

Fig. 2—Clamping the three laminations together after they have been glued

In support of the contention that this laminated-ash frame is lighter and stronger than steel a number of tests were made in the Franklin factory. Pieces of ash 4 inches wide and 2 inches thick were obtained. They were as follows: solid piece, 2,370; thoroughly seasoned, laminated piece, 2,500; laminated piece, sap wood material, 1,950. It is thus seen that the thoroughly seasoned, well glued piece of ash wood was the strongest of the three sorts tested.

At the same time tests were made of channel steel of the same comparative size as would be used in making a chassis frame of the size for which the wood pieces are used. Low carbon and chrome nickel steel were used. In no case did the unit weight load get above 1,550 pounds whereas it went as low as 625. The piece which gave the 1,550 pounds unit weight load weighed 12.25 pounds, and was 4 1-2 inches high, 1 13-16 inches wide and was 2-10 of an inch thick, while the strongest piece of ash weighed but 6.25 pounds

The steel tested was what would probably be used in making a chassis frame and on this comparison, which was actually the best, the engineers were able to show that the laminated wood sill was about 65 per cent. stronger and weighed 50 per cent. less.

Handy List of Future Competitive Fixtures

Race Meets, Runs, Hill-Climbs, Etc.

July 20-28..........Minneapolis Reliability Run, Minnesota State Automobile Association.

July 29..........Cincinnati, O., Hill Climb, Cincinnati Automobile Dealers' Assn.

July 29..........Philadelphia, Track Races, Point Breeze, Quaker City Motor Club.

July 29..........Richmond, Va., Reliability Run, Richmond *Virginian*.

Aug. 3-5..........Galveston, Tex., Beach Races, Galveston Automobile Club.

Aug. 7..........Chicago, Ill., Commercial Reliability Run, Chicago *Evening American*.

Aug. 8..........St. Louis, Mo., Reliability Run, St. Louis Automobile Mfrs' & Dealers' Assn.

Aug. 12-18..........New Orleans-to-Memphis Good Roads Tour, New Orleans *Picayune*.

Aug. 12..........Philadelphia, Reliability Run, Quaker City Motor Club.

Aug. 12..........Worcester, Mass., Hill Climb, Worcester Automobile Club.

Aug. 17..........St. Louis, Mo., Reliability Run, Missouri Automobile Assn.

Aug. 25-26..........Elgin, Ill., Stock Chassis Road Race, Chicago Motor Club.

Aug. ....Cheyenne, Wyo., Track Races, Cheyenne Motor Club.

Sept. 1..........Oklahoma, Reliability Run, *Daily Oklahoman*.

Sept. 2-4..........Brighton Beach, N. Y., Track Races.

Sept. 4..........Denver, Col., Track Races, Denver Motor Club.

Sept. 7-8..........Philadelphia, Track Races, Philadelphia Auto Trade Association.

Sept. 7-9..........Hamline, Minn., Track Races, Minnesota State Automobile Association.

Sept. 7-10..........Buffalo, N. Y., Reliability Run, Automobile Club of Buffalo.

Sept. 12-13..........Grand Rapids, Mich., Track Races, Michigan State Auto Association.

Sept. 15..........Knoxville, Tenn., Track Races, Appalachian Exposition.

Sept. 16..........Syracuse, N. Y., Track Races, Automobile Club and Dealers.

Sept. 18-20..........Chicago, Ill., Commercial Reliability Run, Chicago Motor Club.

Sept. ....Brighton Beach, N. Y., Twenty-four-Hour Race.

Sept. ....Denver, Col., Track Races, Denver Motor Club.

Sept. ....Detroit, Mich., Reliability Run, Wolverine Automobile Club.

Sept. ....Steubenville, O., Hill Climb, Automobile Club of Jefferson Co.

Oct. 3-7..........Danbury, Conn., Track Races, Danbury Agricultural Society.

Oct. 7..........Philadelphia, Fairmount Park Road Races, Quaker City Motor Club.

Oct. 9-13..........Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.

Oct. 13-14..........Atlanta, Ga., Track Races.

Oct. 16-18..........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.

Nov. 1..........Waco, Tex., Track Races, Waco Auto Club.

Nov. 2-4..........Philadelphia, Reliability Run, Quaker City Motor Club.

Nov. 4-6..........Los Angeles-Phoenix Road Race, Maricopa Auto Club.

Nov. 9..........Phoenix, Ariz., Track Races, Maricopa Automobile Club.

Nov. 9, 11, 12..........San Antonio, Tex., Track Races, San Antonio Auto Club.

Nov. 27..........Savannah, Ga.—Vanderbilt Cup Race, Savannah Automobile Club.

Nov. 30..........Los Angeles, Cal., Track Races, Motordrome.

Nov. 30..........Savannah, Ga., Grand Prize Race, Savannah Automobile Club.

Nov. ....Columbia, S. C., Track Races, Automobile Club of Columbia.

Dec. 25-26..........Los Angeles, Cal., Track Races, Motordrome.

Date indef..........Port Jefferson, L. I., Hill Climb, Port Jefferson Automobile Club.

Date indef..........Riverhead, L. I., Road Race, Port Jefferson Automobile Club.

Foreign Fixtures

Aug. 6..........Mont Ventoux, France, Hill Climb.

Sept. 2-11..........Roubaix, France, Agricultural Motor Vehicle Show.

Sept. 9..........Bologna, Italy, Grand Prix of Italy.

Sept. 10-20..........Hungarian Small-Car Trials.

Sept. 16..........Russian Touring Car Competition, St. Petersburg to Sebastopol.

Sept. 17..........Semmering, Austria, Hill-Climb.

Sept. 17..........Start of the Annual Trials Under Auspices of *l'Auto*, France.

Oct. 1..........Gaillon, France, Hill-Climb.

Oct. 12-22..........Berlin, International Automobile Exhibition.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

NOTHING is more convincing of the broad worth of the automobile for transportation purposes than the illustrations that are given in the leading story of THE AUTOMOBILE of this issue. These illustrations show by comparison the roads that are devoted exclusively to automobile service, alongside of the roads that entertain horse-drawn vehicles. The roads that are used exclusively by automobiles are sanitary and smooth in the examples given, whereas the roads that are used by horse-drawn vehicles are anything but sanitary, nor are the surfaces smooth. These examples of roads under the set of conditions named are in the nature of positive proof of the lack of acumen and understanding of the men who deprecate the use of automobiles and the elimination of horse-drawn vehicles. It is no longer possible for health officials to carry conviction among intelligent men unless they put themselves on record in favor of banishing horses from the streets of cities, and any argument on the part of road builders that has for its foundation the idea that automobiles have a more marked bearing upon the upkeep of roads than have horses must fall to the ground of its own weight.

* * *

STATISTICS, as they relate to the maintenance of freight automobiles, lose much of their force, due to lack of discrimination of the compilers thereof, who fail to take into account the advances that have been made in gasoline freight automobile building within a year or two. Freight automobile service has been developed in the City of New York to a greater extent, perhaps, than in any other metropolitan center in this country, and in estimating the relative value of types of freight automobiles, account must be taken of the fact that gasoline freight automobiles were barred from docks and warehouses by the unfair rulings of insurance interests, thus making it extremely difficult for the builders of freight automobiles to show the capabilities of their products. The abrogation of these rules has had the effect of improving these freight automobiles and showing to merchants just how capable they are in every-day work.

* * *

GLANCING at the descriptions of motors other than the poppet-valve type, as they are being described in THE AUTOMOBILE, makes it possible to entertain the idea that the United States Patent Office is being inundated with patent applications along these lines, and we are confronted by the rather poor methods that at present obtain in the Patent Office in handling these matters. It is now the common understanding that the unfortunate inventor who receives Letters Patent of the United States in recognition of a service will have to view such Letters Patent in the light of punishment rather than in the form of protection, according to the theory of patent law. If a man who is the owner of a patent, wishing to protect himself against infringers, calls upon his attorney for the purpose of getting advice reflecting a fair measure of his rights and reasonable expectations in the event of an action, he is likely to be told that there is no possible way by which an attorney can gauge the possibilities, and that the merits of actions-at-law involving the rights of inventors are too obscured to offer any reward from discussion. If it takes the large force of examiners under the Commissioner of Patents, aided by all the patent attorneys in this country, to produce the chaos that obtains in patent matters, it may not be too much to say that the clearing up of this muddle is far beyond the ability of any man to suggest.

* * *

DELIVERING packages in department store service, if the cost per package is to be reduced to the actual minimum, requires that the freight automobiles in this work shall be designed according to the needs as indicated by the best expression of experience. It seems to be true that a freight automobile of considerable capacity carrying a large number of packages, utilizing even ten or twelve runners, is superior to a delivery wagon utilizing the services of a driver and one runner, due to the fact that the boys who serve as runners are swift and tireless, and the large-capacity freight automobile is permitted to traverse a main avenue at a fairly good rate of speed, while the boys who serve as runners take the packages from this freight automobile, delivering them to residences within a radius of 500 feet on both sides of the main avenue, at a saving in the first cost of the freight automobiles used, a considerable saving in wagon maintenance, and with a large reduction in the cost of labor required in the service. Modifications of the main plan must be made, depending upon the locality and attending details, but the fact remains that the trend in this field is in the direction of freight automobiles of considerable tonnage, rather than in the use of light delivery wagons.

Fortune for Motor Fire Engines

New York to Spend $700,000 for Apparatus

By order of the Fire Commissioner a board consisting of four well-known members of the department has been formed to take up the subject of completely motorizing the fire department of New York. The committee, which is now in session, is charged to examine and test all available makes of engines and at present there is a vast sum available for purchases. It is expected that the department will be fully modernized in two years.

VIGOROUSLY advocating the purchase and installation of automobile fire-fighting apparatus, the Fire Commissioner of New York has named a special board from among the technical officers of his department to examine, test and report upon the various types of apparatus available for this purpose. This board consists of Deputy Commissioner Farley, of Brooklyn; John Kenlon, Acting Chief of Department; Chief John P. Howe, and Captain Charles Demarest.

The board is now in session preparing for the details of actual work. So far about a dozen different kinds of fire engines propelled by gasoline motors have been considered, and when the list is complete it is believed that between 40 and 50 different makes will have been tested. Manufacturers have been invited to submit data to this board and a vast mass of material of that sort has been sent in or personally submitted.

The requirements of the department are severe and the tests that have been conducted have been exceedingly searching. It is believed by those in the best position to know that the complete motorization of the department will require about two years. Last spring it was thought that it would take about four years to displace every piece of horse-drawn apparatus.

At present the amount of money available for this purpose is $700,000, and this will be increased when needed for actual expenditures. It was announced at headquarters on Wednesday that the work of the board could hardly be completed before the end of this year, but that much would be accomplished in the meantime looking toward this end.

The experience of the New York fire department with automobile apparatus so far has been satisfactory and at this time it is said that there are over 40 pieces of mechanism now being built for the department or in course of transit from the factories to New York.

Thompson Avenue Grade Scores Again

Another automobile was smashed on the Thompson avenue grade crossing of the Long Island Railroad Monday, snuffing out the life of the driver of the car and severely injuring two women. The Thompson avenue crossing is a nightmare to the automobilist of New York. It is on the main artery of travel toward the interior of Long Island, north of the regular routes through Brooklyn proper.

The busiest section of the railroad is traversed by the road at grade, the crossing being a maze of steel tracks. There are gates on each side of the right of way, and at almost any hour of the day or night automobiles may be found lined up on both sides of the crossing waiting their chances to scurry across between the silently rushing trains.

In the busy hours of the day the automobiles are frequently obliged to wait for a half hour to cross.

The Long Island Railroad has always taken a great interest in automobiling, and it has been active in a legislative way to "regulate" automobile traffic so that it might not prove too attractive to possible commuters.

In the case of this accident three cars were crossing when a train bore down upon them while the gates were raised, the way apparently clear and safe.

It is stated that 352 trains pass the crossing every weekday. A contract has just been entered into between the city and the railroad to abolish this and other crossings and the city's portion of the expense is to be $600,000.

Jersey Kills Eight-Day Permits

Perfectly consistent with its action in closing the doors of the State to free touring, New Jersey has now abrogated the eight-day touring license that has served instead of a more generous provision. Commissioner of Motor Vehicles J. B. R. Smith has made the announcement that the eight-day provision is no longer in effect and already a howl has been raised by automobile owners in New York, which has an echo in the hearts or pocketbooks of the hotel owners along the Jersey coast.

In substance the Legislature at its recent session declared that Jersey does not want automobile tourists, despite the piercing cries of disapproval from the hotel men. By its refusal to pass reciprocal legislation the lawmakers place themselves on record as forbidding the free entry of the State to automobiles that have complied with the laws of their home States, unless their owners took out full touring licenses for the year.

The injustice of such action is made apparent when it is realized that there are no such strictures placed upon traffic other than that represented by the automobile. Officials of the A. C. A. have taken up the matter with Commissioner Smith, and the announcement is made that all hope of some mitigation of the order has not been abandoned.

H. A. Bonnell, general manager of the A. B. of T., who is a leading member of Jersey motordom, says he is heartily disgusted with the trend of events and sees little hope for amelioration of conditions in the immediate future.

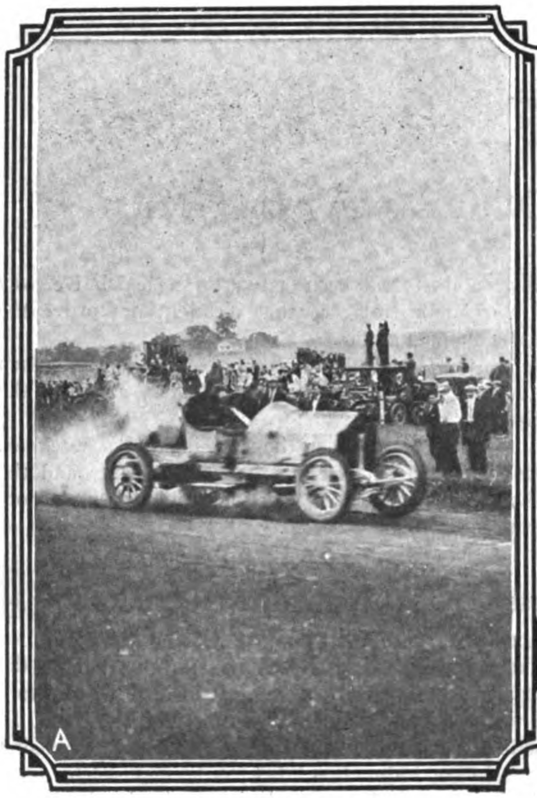
Rules for N.A.A.M. Show

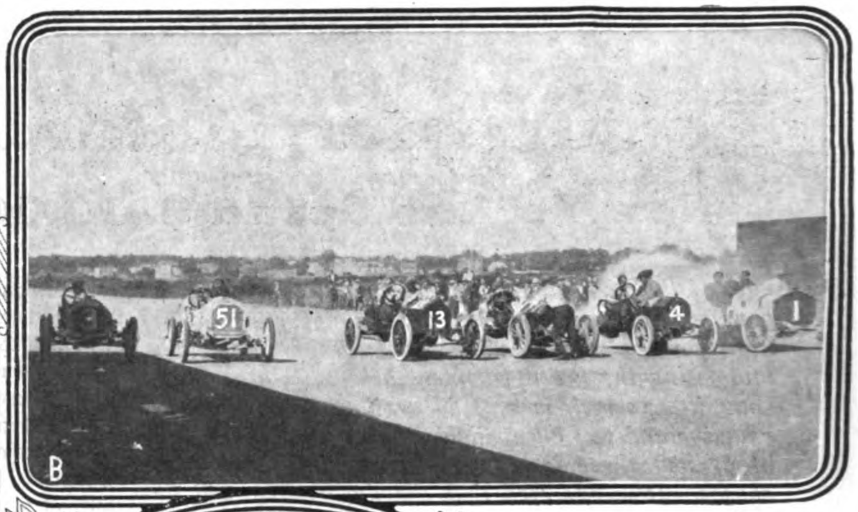
Rules to govern the Twelfth Annual National Automobile Exhibition, which will be held at the Grand Central Palace, New York, January 10-17, 1912, have been issued. These provide that exhibitors at unsanctioned shows shall be barred. The main and second floors of the building will be used for pleasure car displays and the wall spaces for the commercials. Accessories will be displayed on the third floor. Price of space is $1.25 a square foot. One-half of the net proceeds will be rebated to exhibitors. General admission will be 50 cents.

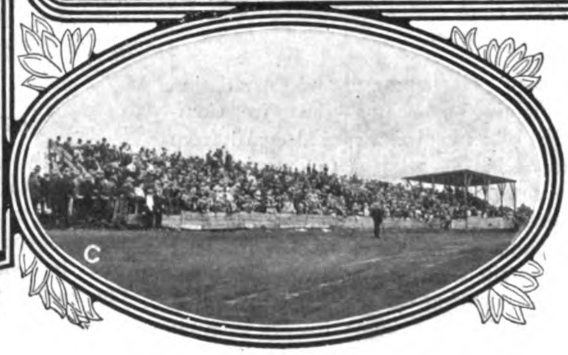
Blue Book Crew Finds Good Roads

BANGOR, ME., July 24—The Blue Book automobile now touring in upper New England had a busy time last week. The car was driven from New York to New Haven, to Hartford, Springfield, Pittsfield, Greenfield, Brattleboro, Keene, Nashua, Portsmouth, Boston, Concord and the White Mountains.

Good roads were encountered everywhere except between Greenwich and Norwalk and Nashua and Concord and a few short stretches in various places.







A—National, winner of third race, rounding the lower turn.

B—Line-up of starters in ten-mile race — National, Marmon, Mercer, Pullman, Jackson, E-M-F

Ten-Mile Track Mark Lowered

Guttenberg Crowd Sees New Record Made

A big half-holiday crowd attended the Guttenberg race meeting on Saturday and saw a Simplex car set a new mark for the ten-mile distance, and then in the next race witnessed the same car knock a dozen seconds from its own speed record. The races were rather tame from the contest point of view and in only one of the six events run off was there anything that looked like a struggle. This came in the 451 cubic inches class and the winner, a National, after being left at the post and pocketed for several miles, worked its way through to win rather easily.

THERE were no thrills about the racing at Guttenberg last Saturday, the program failing to develop anything spectacular. But on the other hand there was nothing that savored of mishap during the afternoon's sport and the big crowd saw the ten-mile record of the track lowered in two successive races. A 50-horsepower Simplex was the medium and after setting the new mark for the distance at 10.43 3-5 in its class race, it knocked off over 12 seconds from that time in the Free-For-All, placing the new track mark at 10.31 1-5, which will not be disturbed for some time in all probability.

There were five events carded and a match race was added and the number that created the most interest in the running was third on the program.

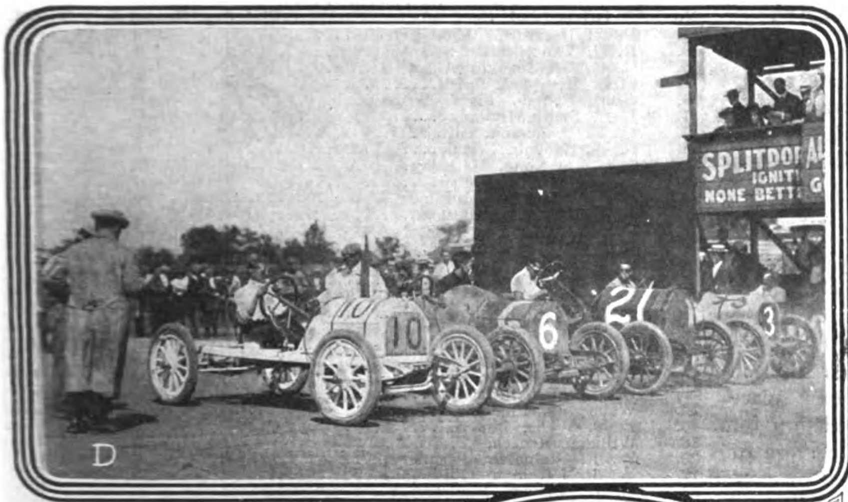
In this race four cars were entered and two added at the post. National No. 1 proved to be the winner after being practically left at the post. The Marmon entry jumped away at the start and opened up a comfortable gap in the first three miles, followed by the E-M-F and Mercer. The latter was going well at five miles but seemed to develop some trouble with its carbureter in the latter stages and could not get up enough speed to stay with the leaders. The National started last and was in a deep pocket for several miles, but along toward the eighth mile it began to loom up like a winner and gradually worked through to the front, not being pushed at the end. The Marmon apparently had the race won at one stage but faltered in the last mile, lasting long enough to get the place from the Mercer, which acted stiff and did not respond to De Palma's urging. This car was not properly tuned up before the races.

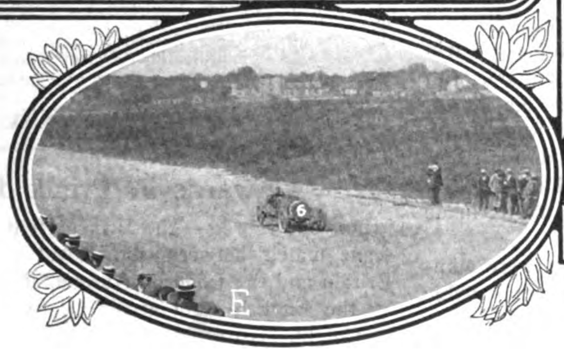
The first race was a small class event and was won all the way by the E-M-F entry, the Paige-Detroit being in closest attendance at the finish. The second race was also taken by the E-M-F, which beat the gun and made the pace from end to end. The Pullman was second all the way.

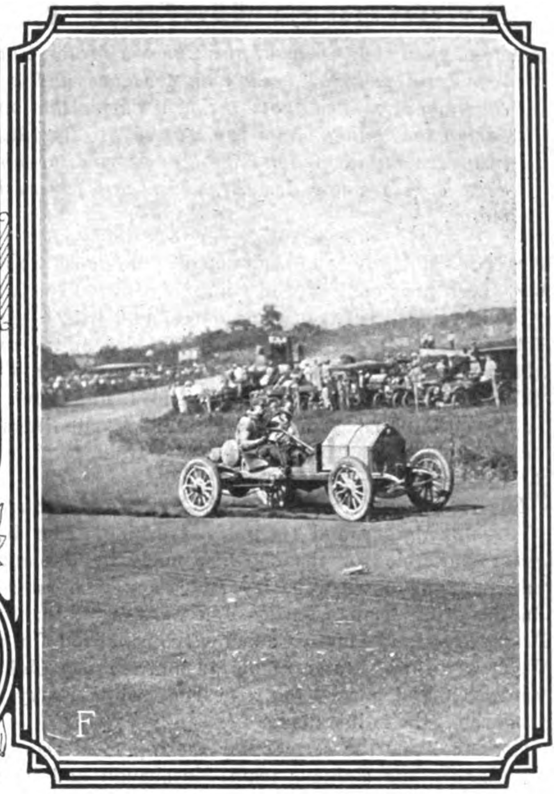
The match race was a procession with the Staver leading the way.

In the big class event the National beat the gun rather flagrantly but was soon overhauled by the Simplex and the rest of the race was uninteresting save for the fact that a new mark for the distance on this track was established only to be overthrown in the next race by the same car. The National was second, Marmon third, and the Jackson blew a tire and did not finish.

In the Free-For-All there was nothing to it but the Simplex which got away with the leaders and outfooted the field. As in the preceding event the National was second and the Marmon







D—Line-up for the five-mile "under 231" race—E-M-F, Overland, Lancia, Paige-Detroit

E—There was a goodly turnout of cars and railbirds

F—Staver winning the five-mile match race

third. The Pullman and Staver contestants did not figure in the running. Limberg was sharply cautioned by Referee Camacho for beating the gun but was not set down.

The track looked as if it needed oil and it certainly was helped materially by the rain of the night before. The club house and the far turns were in bad shape after the first three races had been run and T. B. Shoemaker of the Contest Board made an inspection. He cautioned the drivers to observe special caution in rounding them. A. F. Camacho handled the flags and acted as referee and gave satisfaction. It is estimated that there were between 3,000 and 4,000 present. The summary:

Five Miles Class E Under 231 Inches

No.	Car.	Driver.	Position.	Time
3	E-M-F.	Tower	1	5:47⅘
10	Paige-Detroit	Craig	2	
6	Lancia	Ferguson	3	
21	Overland	Gastieges	No finish.	

Five Miles Class E Under 301 Inches

3	E-M-F.	Tower	1	5:38⅖
13	Pullman	Burke	2	
10	Paige-Detroit	Craig	3	
8	Correja	Gillam	4	
23	Staver-Chicago	Du Closne	5	
6	Lancia	Ferguson	6	
7	Mercer	De Palma	No finish.	

Five Miles Match

23	Staver-Chicago	Du Closne	1	6:40⅖
50	Correja	Gillam	2	

Ten Miles Class E Under 451 Inches

1	National	Limberg	1	11:13⅕
4	Marmon	Rouse	2	
7	Mercer	De Palma	3	
13	Pullman	Burke	4	
51	Jackson	Cobe	No finish.	
3	E-M-F.	Menges	No finish.	

Ten Miles Class E Under 601 Inches

2	Simplex	De Palma	1	10:31⅕
1	National	Limberg	2	
4	Marmon	Rouse	3	
51	Jackson	Cobe	No finish.	

Ten Miles Free-for-All

2	Simplex	De Palma	1	10:43⅗
1	National	Limberg	2	
4	Marmon	Rouse	3	
13	Pullman	Burke	4	
23	Staver-Chicago	Du Closne	5	

Quakers to See Speed Contests

PHILADELPHIA, July 24—Nine events are listed on the program for the fifth annual midsummer track meeting of the Quaker City Motor Club on the one-mile circular race course of the Philadelphia Driving Club at Point Breeze Saturday next, the entry blanks for which were issued this week. The series of races comprises four non-stock cars, divisions 2C, 3C, 4C and 5C, each 10 miles, for a money prize; one-mile exhibition for track record; class D, free-for-all, 5 miles, flying start, for the Remy Grand Brassard and Trophy; a 10-mile open handicap; match race between Burman and Knipper, and a 25-mile combination race.

The meet promises to be second only to the Fairmount Park road race in point of interest, for the country's speediest and most daring drivers will compete for the rich stakes which will be hung up.

Picking Out Virginia Road

CULPEPER, VA., July 25—With the good wishes of Vice-President Sherman ringing in their ears three cars containing a number of good roads boosters left Washington yesterday en route to Richmond.

F. H. Elliott, secretary of the Touring Club of America, and Henry McNair, of the Blue Book, are in charge of the party, which consists of government and State road officials. The object of the trip is to pick out a good road south from Washington to Richmond over which a large number in Richmond in October will travel. That Virginia is alive to the good roads movement was manifested to the tourists in no uncertain manner. Enthusiastic greetings were extended them all along the line and the trip is bound to give the movement a big impetus.

Scenically Virginia is ideal, but its roads leave much to be desired. With a good system of roads it would prove a great touring ground. The present trip will do much to advance the cause. Vice-President Sherman gave the signal which started the tour and expressed his great interest in the work of the touring club.

Amateurs Defeat Trade

In two-day reliability run of the Chicago Motor Club, the amateur team won the honors on the road and a new set of champions resulted from the field games that were enjoyed during the outing. The run was to St. Joe, Mich., and return, 222 miles. On the first day's run the amateur team drew only a single demerit, which was caused by a stalled motor.

CHICAGO, July 24—Undoubtedly the most enjoyable affair ever promoted by the Chicago Motor Club was the team reliability match between the amateur and trade members of the club, with which was combined a field day at the night stop, in which contestants had a chance to demonstrate their skill in athletics other than motoring. The team match took place Thursday and Friday of last week and resulted in a victory for the amateur team, which defeated its trade rival by a score of 221 to 287.868.

The match was to St. Joseph, Mich., and return, a distance of 105 miles going and 117 miles returning. The first day's trip was remarkable for the showing made by the amateurs, who only had one down—Charley Anderson, who killed his motor. On the other team, Charley Van Sicklen, William Roesch, W. D. Foreman and Harry Cooper were penalized for motor stops, Webb Jay found water in his gasoline, Tracy Holmes broke a crankshaft and burned out a bearing, while Harry Watts made a steering gear adjustment.

Coming home the second day more perfect scores were eliminated. On the amateur team Sinsabaugh had ignition trouble and never got away from St. Joe; N. H. Van Sicklen, Sr., was penalized when a chain jumped the sprocket, Claude Anderson was demerited heavily for work done, while Gaidzik and Laramie had motor stops. Charley Van Sicklen, of the trade team, changed a spark plug, Gregory had a motor stop, Watts did work and was arrested for scorching.

The trade team had sixteen drivers and the amateurs fourteen, therefore the dealers only were penalized 14-16 of a point instead of a full point. This drew the finish fine, because for a time it looked as if Claude Anderson would not finish. The rules penalized for work done and for being late at controls.

The field day sports were enjoyed by everyone. The baseball game was good, but the other events were more interesting. Swimming, golf, running, jumping, pool and bowling kept everyone interested and resulted in a new set of champions. The standing of the team match is found in the accompanying table:

AMATEUR TEAM

No.	Driver and car.	First day.	Second day.	Total.
1.	David Beecroft, Abbott-Detroit	0	0	0
3.	N. H. Van Sicklen, Sr., Apperson	0	1	1
5.	C. G. Sinsabaugh, Abbott-Detroit	0	150	150
7.	C. G. Heywood, Buick	0	0	0
9.	George Knab, Pierce-Arrow	0	0	0
11.	J. H. Smith, Halladay	0	0	0

Some of the contestants in the Team Reliability Match between Trade and Amateur Members of the Chicago Motor Club

Awards in Prince Henry Tour

LONDON, July 24—The Prince Henry trophy, chief prize in the team match between the Royal Automobile Club of Great Britain and the Imperial Automobile Club of Germany, was won by the English team according to announcement made Thursday night. No scores were announced.

His Majesty the King's cup, a commemorative prize, went to the German club, while His Imperial Majesty the Emperor's cup was awarded to the Imperial club. Her Majesty the Queen's cup for the best appointed car on the German team was given to Landrat von Marx with an Opel, while the corresponding trophy given by the German Empress to the best appointed car on the English team was presented to N. C. Neill with a Rolls-Royce. Princess Henry of Prussia gave a cup for the next best appointed car on either team, which was awarded to F. C. Bowring, who drove a Daimler.

Clean Scores in Cleveland Run

CLEVELAND, OHIO, July 24—The awards in the Cleveland *News* reliability run, made here Saturday morning, show that fourteen cars out of thirty-seven went through the test with perfect scores.

A small number of cars in the run came through without tire trouble of any sort. The large majority of the observers' cards, however, showed that the drivers in the run had tire delays.

The success of the run was in large measure due to the enthusiasm and earnestness of the officials. They were St. Claire Couzzens, of the *News*, referee; Fred Caley, secretary of the Cleveland Automobile Club, checker; Peter Mayer, starter; E. E. Grimes, A. A. A. representative, and Harry Smith, chief observer.

Fiat Wins French Grand Prix

PARIS, July 24.—Hemery in the Savannah Grand Prix Fiat was the only survivor in the French Grand Prix run over the Sarthe circuit, a distance of 402 miles, covering the distance in 7:06:30, an average of 56.54 miles per hour.

When the race was called off the little Bugatti 8-horsepower driven by Freiderich was in second place, having completed ten of the twelve circuits, or 334 miles, in 7:16:50. Gabriel in a Rolland-Pilain did nine rounds in 8:04:38 and Leduc in a Cote, eight laps in 6:19:33.

Maurice Fournier and his mechanic were killed in the seventh round, caused by the front axle breaking and the car going into the ditch. Fourteen cars started.

Eleven Entries for Glidden

So far eleven entries have been made for the tentative Glidden tour of 1911, leaving a minimum of nineteen more entries to be received prior to the time set for closing the lists on August 1.

Announcement has been made that unless at least thirty cars are entered there will be no tour this year. Strong hope is expressed that the list will fill satisfactorily and that the run from Washington to Ottawa, 1,089 miles, will be held some time in September. It is pointed out by those interested that a test of current or advance models in the fall must act as a live selling impulse to the trade, it being a notorious fact that Fall selling is about four times as difficult as Spring selling.

The list of entries so far is as follows:

1911 Cunningham model "H" (pacemaker).
1911 Oakland model "M."
1911 Ohio model "40."
1911 Abbott-Detroit model "B-11" (three cars).
1911 Washington model "D-40."
1911 McIntyre model "M-6."
1912 Maxwell (three cars).

Buffalo Club Plans Big Run

BUFFALO, July 24.—The second annual reliability tour for the Laurens Enos and other trophies, to be held under the auspices of the Automobile Club of Buffalo, will be run September 6-9 over a course of 800 miles, thoroughly covering Western New York, from Lake Erie to Lake Ontario. Entries for the event close on August 15.

Queen Cityans Will Climb

CINCINNATI, July 24.—The committee in charge of the Stanley Hill climb for Saturday, July 29, are assured of a successful event as to arrangements and entries.

Fully a dozen different makes of cars have already been entered. The contest is under the auspices of the Cincinnati Automobile Dealers' Association, and has sanction number 371 of the Contest Board.

Stanley Avenue hill is 2,340 feet in length. On one side of the course there is ample room for 20,000 spectators commanding an unobstructed view of the entire race. Both sides of the course will be protected from end to end with wire rope, in addition to which Chief Jackson has engaged to furnish 200 or more policemen to assure a clear course.

The program embraces eight events of which interest seems to center in Nos. six and eight, the former being for automobile club members only, and the latter a free-for-all.

Premierites Nearing Pacific

RAWLINS, WYO., July 24—The transcontinental tour of the Premier flotilla of ten cars is over two-thirds of the way across the country.

War Automobiles Arrive

Six cars manned by cadets and equipped with balloon fighting guns and wireless reached New York Tuesday, after a tour from Chicago to Washington. Maneuvers were held near the National capital on a broad scale. Major Davidson of the regular army is in command.

SIX war automobiles manned by students of Northwestern Military Academy, Highland Park, Ill., and equipped with rapid fire guns capable of elevation to any angle for balloon destruction, arrived in New York Tuesday on their return trip from the field of special maneuvers at Washington.

Major Davidson of the army is in command of the party and under his direction the students have been making a special study of combatting balloons and other air craft in a military sense.

All the cars are fitted with guns capable of being handled by one man and two of them have complete wireless equipment as well as several balloon envelopes. The expedition will return to Highland Park by easy touring stages.

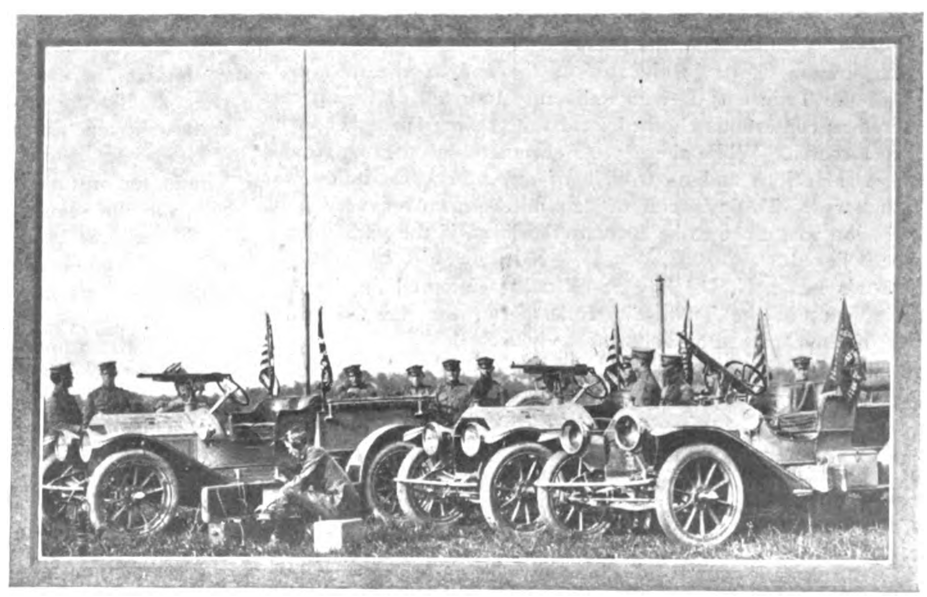
Armleder Enters Automobile Field

CINCINNATI, July 24.—An event of considerable importance to Cincinnati and to the automobile interests is the entrance of The Otto Armleder Company to the ranks of manufacturers in the automobile industry. This decision is the result of about two years of exhaustive experiments, especially in the line of a delivery vehicle of capacity for about one thousand pounds to meet the demands of medium and light transportation such as laundries, dry goods, millinery, &c.

The vehicle will be called the "Armleder". J. Biederman, who has for many years been in the manufacturing plant of the Armleder Company, is the designer of the new machine.

Havers Plant to Be Enlarged

PORT HURON, Mich., July 24—It has been stated that orders for approximately 280 cars, or nearly $500,000 of gross business, have been placed with the Havers Motor Car Company in the past few days and plans are now being formulated to immediately increase the capital of the company and the capacity of the plant. Several offers of large amounts of outside capital have been made, but have been rejected, as the present stockholders prefer to keep the enterprise a strictly Port Huron industry.



Businesslike balloon-fighting equipment of the students of the Northwestern Military Academy, Lake Forest, Ill.

Minnesota-Helena Tour Now On

Third Day Kills Many Perfect Scores

With nineteen automobiles in the contesting column, the third annual reliability contest of the Minnesota State Automobile Association started from Minneapolis last week on its way to Helena, Mont. The tour is accompanied by a hotel train on the Great Northern Railroad which affords accommodations for the tourists en route.

MINNEAPOLIS, July 19.—Under favorable auspices the Third Annual Reliability Run of the Minnesota State Automobile Association started from this city for Helena, Mont., this morning. There were nineteen contesting starters, but from this number must be deducted the Kisselkar pair, the Pierce-Arrow 7 and Packard 19 which will compete only in an unregistered or non-stock car class, owing to the fact that stock car certificates for them have not yet been issued.

The tour has been routed so that it parallels the Great Northern Railroad and a special hotel train accompanies the tourists. The train provides accommodations for 150 people and will stop at all the noon and night controls to serve meals and provide sleeping quarters.

The list of starters included the following:

Car No.	Make	Driver
1	Maxwell	O. W. Klose
2	Marmon	John Fawkes
3	Amplex	P. Kenneth Wiseman
4	Halladay	O. A. Palmlund
5	Kisselkar	C. L. Bonwell
6	Kisselkar	Chris Rice
7	Pierce-Arrow	Julius Suckow
8	Hupmobile	E. B. Stimson
9	Abbott-Detroit	A. N. Smith
10	Stoddard-Dayton	J. H. Prior
11	Colby	M. G. Armstrong
12	Flanders	B. M. Scott
13	Flanders	F. A. Witte
14	Flanders	George Herron
15	Krit	J. E. Dougherty
16	Petrel	A. L. McNurlen
17	Cole	B. Terrell Hoyt
18	Cole	C. L. Rose
19	Packard	W. Stork

The referee is E. P. Dutton and pilot, C. S. Harrington, who laid out the route last spring following the line of march of the Lewis and Clark expedition. The pilot car is a Halladay, the pacemaker a Corbin, and the press car a Pierce-Arrow.

ALEXANDRIA, MINN., July 20.—At the end of the first day's run of the Twin City-Helena Reliability tour, all of the 19 cars entered as contestants checked in at the parking space here with perfect scores. While there were several cases of tire trouble none was serious and no trouble of any other description was encountered. To-day's run of 140 miles was over very good roads, but worse are to be encountered later, if the pathfinder is to be believed.

DEVIL'S LAKE, N. D., July 22—Penalties imposed on the contesting cars in the Twin City-Helena run for the first three days of the tour are as follows:

No.	Car.	Penalty.	Cause.
15	Krit	6	Replacement of broken steering arm.
16	Petrel	3	Taking on water.

With only two cars penalized during the first three days of the reliability run from the Twin Cities to Helena, Mont., all checked in here to-night on time. None of the contesting cars has had any accidents other than those for which penalties were imposed.

The roads from Fargo were excellent and the tourists ran ahead of schedule. Almost all the way was over smooth, hard gumbo, which makes the finest kind of road when dry as it was this morning.

Soon after leaving Grand Forks it commenced to rain, which lasted all the afternoon, and the motorists were afforded a sample of wet gumbo. Tire chains became a necessity and even then the cars skidded badly at times.

The town of Devil's Lake was reached about seven in the evening. The tourists rest up here over Sunday and will check out for the next run of 167 miles to Berthold Monday morning.

BERTHOLD, N. D., July 24—Penalties for first four days of Twin City-Helena tour:

No. 15, Krit, second day, 12 points; third day, 38 points; total, 50 points.

No. 16, Petrel, third day, 3 points; fourth day, 12 points; total, 15 points.

No. 11, Colby, second day, 2 points.

No. 18, Cole, fourth day, 461 points.

No. 1, Maxwell, fourth day, 121 points.

No. 4, Halladay, fourth day, 36 points.

No. 3, Amplex, fourth day, 6 points.

The first car to suffer penalization was the Krit, which was assessed for the replacement of a steering arm. On the next day the replacement of two steering knuckles caused the assessment of the 38 points in addition. The 3 points against the Petrel were imposed for taking on water out of control, while the Colby was penalized for hooking up a loose wire on the accelerator.

To-day's run from Devil's Lake to the night control here is the hardest of the trip. In spite of this a schedule of 20 miles an hour was maintained and all but one of the contestants checked in before their time limit had expired.

The Stoddard-Dayton and the Cole 30 were the only cars to fall behind the schedule. A broken rear axle, sustained when the former made a wrong turn and the car ran into a coulee, laid it up for about two hours while repairs were being made by a neighboring blacksmith. None of the occupants was injured, but the driver and entrant, J. S. Prior, withdrew the entry from the run, intending to have repairs made and continue as a noncontestant. Upon his arrival at the night control with the car in running condition, Referee Dutton was petitioned by the other contestants in his class to allow Prior to continue as a contestant. The referee then permitted the car to check in as a contestant and assessed the penalties provided.

Many perfect scores were spoiled to-day by the rough roads. The motor on the Amplex, No. 3, stopped twice by the failure of the hand fuel pump to work. The Halladay, No. 4, sprung a leak in the gasoline tank and lost all its fuel, requiring two stops of 15 and 18 minutes respectively. The gas tank was removed and soldered. This car also lost a tire iron and the tail lamp.

Maxwell, No. 1, broke its fuel pipe after having been on the road only 20 minutes and was detained 12 minutes.

The Petrel added to its score by breaking both front springs. Temporary repairs were made by blocking them up with wood.

J. E. Dougherty, driver of the Cole, No. 18, distinguished himself to-day by making a novel repair of his gear-shifting mechanism in making a quick stop after taking the wrong road on the second day of the run. A lug on the gear shift arm was sheared off, preventing the use of any but high speed; after running a day and a half on the high, during which time it was necessary to both start and take all the hills on the high gear.

Imperial Wins Trophy

An Imperial touring car penalized one point won the sweepstakes prize, the Milwaukee Sentinel Trophy in the Wisconsin State A. A. run last week. A Ford car was first in the roadster division while a Franklin took the honors in the privately owned division. Lewis Strang, racing driver, was killed by a caving bank during the tour.

MILWAUKEE, WIS., July 25—With but a single point charged against its record, a 1911 model 44 Imperial touring car, driven by Harry Bisbee, of Jackson, Mich., won the second annual reliability contest of the Wisconsin State Automobile Association, taking down the Milwaukee *Sentinel* sweepstakes trophy for a year and the Milwaukee *Journal* cup for touring cars, for permanent possession.

The Ford was close behind the Imperial and with its 2-point penalty won the Milwaukee *Evening Wisconsin* trophy for roadsters, to be held permanently.

The car was driven by William H. Diener, and entered by the Hickman, Lawson Diener Company, State agent.

The Emil Schandein trophy for one year's possession by the privately owned car making the best showing was awarded to J. D. Babcock, whose model "D" Franklin incurred a penalty of 17 points under the Grade 3 rules governing this division, and a 61-point penalty under the Grade 1 rules governing the trade classes, in which Mr. Babcock also entered and drove his car. The model R Reo, the only 1912 model in the tour, made an excellent showing, taking second place in the touring car class with only 6 points chalked up against it.

The Imperial's 1 point was incurred in the final technical examination, a bolt on the mudpan being found loose. It was at first thought that there was a radiator leak, but exhaustive tests showed this to be perfect. The car was gone over again, but no fault could be found and the final penalty was 1 point.

The model T Ford was a close contender with the Imperial for first honors. Diener incurred a penalty of 1 point for motor stop on the fifth day's run, and an additional point was imposed in the technical for a leaky water connection.

August A. Jones' No. 1 Cadillac, which made a beautiful run on the road and came through the brake clutch and motor tests clean, being touted as the winner, fell down on the final. Three points were imposed, 1 for a leaky connection and 2 for loose cap screws.

The winning Imperial's team mate, No. 7, stood fourth in the roadster division with 8 points. Herb Crampton lost 6 points in the brake test and 2 in the technical for loose bolts. The Warren Detroit made one of the best performances of any car and Rockstead was the only one to come through the final examination with a perfect score. However, he had been assessed 12 points for putting sand on a slipping clutch on the road and 2 points in the brake test.

The final result and penalizations, regardless of class or division, was as follows:

No.	Name of Car.	Driver.	Penalty.
8.	Imperial	Harry Bisbee	1
6.	Ford	W. H. Diener	2
1.	Cadillac	A. A. Jones-Fuhrmann	3
9.	Krit	W. G. Westwood	4
5.	Reo	A. J. March	6
7.	Imperial	Herb Crampton	8
15.	Warren-Detroit	R. D. Rockstead	14
12.	Overland	R. B. Bates-Heber	22
10.	Case	Will L. Jones	29
2.	Buick	Emil Hokanson	31
11.	National	Charles Merz	33
13.	Franklin	J. D. Babcock	61
3.	Buick	Geo. P. Hewitt	63
4.	Buick	Nicolanzzo-Munson	162
14.	Regal	C. H. Delafield	259
16.	Petrel	Jesse J. Mack	1459

Lewis Strang, driver of the technical committee Case car, was killed Thursday near Richland Center. Strang had driven through a toll-gate and had stopped within 3 feet of an embankment waiting for a rig to pass. The bank gave way and precipitated the Case to the bottom. Strang was caught between the running board and ground and died almost instantly.

Detroit News Notes

New automobile ordinance in Detroit has brought about a reign of terror among motorists. Welch-Detroit factory to move to Saginaw and car will in future be known as the Marquette. These plans also contemplate placing the Rainier car in the same category. Lozier will not race on dirt mile tracks. Other items from the manufacturing center.

DETROIT, July 24—Detroit motorists are just now undergoing a veritable reign of terror, due to the strict enforcement of the new traffic ordinance. The limitation of speed outside the mile circle to 15 miles an hour, the provision making it necessary to keep 6 feet or more from a standing street car and the prohibition against passing street cars to the left form the ground for most of the complaints, and the judges of the recorder's court have been assessing fines at a rate which surpasses anything in local history. Two sessions of the court resulted in the collection of more than $2,000 in fines, while there are almost daily instances of heavy penalties.

The approach of the usual relaxation of activity is noted at the local factories. Aside from those already engaged in the production of the 1912 cars, the local factories are, generally speaking, engaged in clearing the decks for the change to new models and in the taking of inventory and the installation of new machinery. The rush of the busiest part of the season is now over and the period of transition finds but few of the plants running at top speed.

A feature of the retail trade this year has been the notable increase in the business done in used cars. One of the largest, best-located and most elaborately equipped of the new garages in the city—that of the Gillespie Automobile Company—is devoted entirely to the sale and repair of used cars. The showroom occupies one of the finest Woodward avenue corners.

An important announcement of the week comes from the General Motors Company headquarters and concerns the Welch-Detroit plant. This establishment has been ordered to prepare for a transfer to Saginaw, where the Marquette Motor Company's plant will be at last transformed into a real motor-car manufactory. The present name of the car will be abolished and the output of the plant will be known as "Marquettes." It is understood that the present Welch-Detroit plans will be carried out on a larger scale at Saginaw and combined with the plans of the Rainier, manufacture of which will also be under the new name.

The matter of racing on dirt tracks, both of mile and half-mile circumference, will be discussed here at the next meeting of the Manufacturers' Contest Association. There is a strong feeling among the manufacturers that such events are so unsafe as to court disaster, injuries to drivers and loss of life. It is not believed, either, that the cause of automobiling in general derives any benefit from such competition. Many of the manufacturers would be glad to sign an agreement not to race cars on such courses and to do all in their power to discourage their agents and owners of their cars from doing so.

Large Garage Opened in New Jersey

Freehold, N. J., is now in possession of what is claimed to be one of the largest garages of the State. It forms part of the building of the Freehold Motor Co., agents for Maxwell and Columbia cars in that territory, who conduct the garage business in addition to a salesroom where accessories and tires are handled. The new building of the company is about 60 by 180 feet, the salesroom being 40 by 48 feet in area, and the garage having a capacity of more than 60 automobiles, 60 by 124 feet. In addition to this there is a machine and repair shop located in the rear of the building, equipped with the necessary tools and containing the air compressor and the power plant of the building. The building is constructed of hollow pile and concrete, thus being fireproof.

New Things Among the Accessories

Rust-Proof Demountable Rim

THE new rim illustrated herewith, and named after Detroit, where it is made, is distinguished by its locking feature which is seen in Fig. 1, showing a small portion of the rim. The lock L1 consists of a flat piece of metal with two segments cut out near its two ends for the ground joints J1 and J2 to fit in. In the center of the locking plate is punched a circular hole fitted around a strong metal ring which is securely fastened into the section of the rim S1, permitting the tire valve stem to come out through the ring. Turning the ring in a clockwise direction unlocks the plate from its relation to the ground joints and permits of lifting the section S1 from the rim without any effort; while, on the other hand, with the locking plate in position the section makes a waterproof fit against the rest of the rim. Furthermore, the lock is automatically held in place when on the wheel, because the construction of the lock assures a close all-along contact with the felloe band.

The second important characteristic is shown in Fig. 6, illustrating the special rust-breaking tool of the Detroit demountable rim. The necessity of a tool to avoid the formation of rust and to permit its eventual breaking off of the tire has long been recognized, and the makers of the Detroit rim claim to have solved this problem. The tool T1 consists of a bolt and two members, of which M1 is movable on the thread and rigidly connected to the shaft C1, while M2 is forged integral with a guiding ring G1 which permits the shaft to rotate in it. The use of the rust-breaking tool is as follows:

If rust formation between tire and rim is suspected or too close adherence between them is to be avoided, the bolt is so turned by means of the handle that M1 is drawn toward M2, thereby contracting the rim, which diminishes its circumference while that of the tire remains unchanged. Consequently, the tire is broken loose from the rim, and for some time insured against rust formation. After the rim has been contracted, removing and replacing a tire is very easy.

In Fig. 6 are also seen the draw bolt B1 and wedge W1 which serve to fasten the rim to the wheel. The simple and substantial construction is clearly indicated by the illustration, and mention is to be made of the fact that a draw flange is used back of the wedge without cutting or weakening in any way any part of the draw bolt, which is half an inch thick at its weakest point. The wider portion of the wedge opening permits the bolt to pass through it easily, and when placed in the wheel the bolt moves up automatically, making a unit with the wedge, which now has to come with the bolt if the latter is removed. Countersunk on the inside of the wheel hard brass nuts are provided to receive the bolt and hold it in place, and the use of brass prevents the formation of rust at this portion of the rim. There are six bolts used to hold the rim on to the wheel, and since the wedges cannot stick and rust in on the rim, the latter almost falls off on account of its weight when the bolts are loosened. Rusting of rim to felloe band is prevented by the special tool, and if they stick, expanding the ring will separate them.

With a set of five rims are furnished all the bolt wedges, felloe plates, end nuts, the rust-breaking tool and one wrench, by the Snyder & Harbridge Selling Company, 247 Jefferson avenue, Detroit.

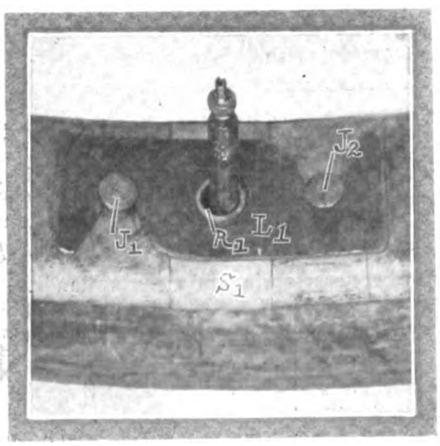


Fig. 1—Showing the tire valve and demountable rim lock closed around it on the Detroit

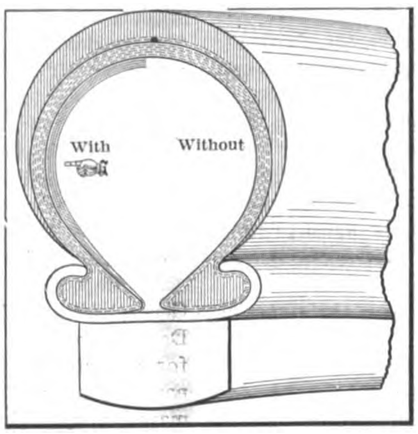

Fig. 2—The Tire Inner-Lining which prevents overheating of tire tubes, and minimizes blowouts

Tire Inner-Lining

BLOW-OUTS may happen while an automobile is running at normal speed, but in the majority of cases they occur when going at a high rate, comparatively, and their relation to the overheating of the tires is a well-established fact. Unfortunately, there is no way of keeping down the temperature of tires in a manner similar to the cooling of cylinders by water-jackets, but the problem of lengthening the life of tires under hard-working conditions resolves itself into an "insulation" being so introduced as to protect the tubes from the heat produced by the friction between tire and road. In the illustration (Fig. 2) is shown the asbestos leather inner lining, which consists of a double layer of asbestos with a stratum of hide interposed and which is placed inside the outer casing, thus shielding the inner tube from the heat. The makers, the Auto Tire Inner-Lining Company, of Cincinnati, Ohio, claim a very material increase of the life of tires where the lining is applied in the manner shown in the illustration.

Hartford Safety Crank

STARTING CRANKS, unskillfully handled, are treacherous; they have caused numberless arms to be fractured, not a few skulls to be broken, equally numerous damage suits to have been brought to court and thousands of dollars to be expended in the abatement of what hitherto has been pretty generally considered a necessary evil. Probabilities are, indeed, that with spark and throttle properly adjusted, and a starting crank pulled up smartly, the operator will get away safely every time he performs this operation; but how many automobilists are there who always keep these simple points in mind? It is a peculiar property of the small objects distributed all over the world that they are extremely malicious.

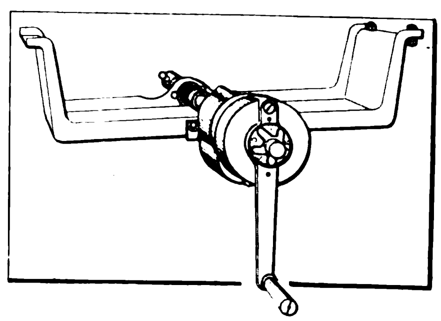

Fig. 3—The Hartford safety crank to overcome the deleterious effects of backfires

and just as pencils, matches, policemen and other desiderata are seldom to be found when needed, a starting crank seems to be awaiting an opportunity to break the arm of an unwary automobilist after having acquired his confidence by apparently tame and harmless behavior.

In such a live industry as that of manufacturing automobiles and their accessories there is no chance of a want being felt and not also being filled soon thereafter. Therefore, as the number of automobiles and with them the number of cranking accidents increased, makers of accessories and various constructors strove to devise some means of starting an engine without the operator being forced to encounter the dangers of the back-kick. Two schemes were adopted by the various makers—the self-starter, and the safety crank.

Describing one of the latest results of endeavor along this latter line, it will be of interest to note that the Hartford Safety Crank, which is made by the Hartford Suspension Company, of Jersey City, N. J., was evolved after three years' continual work. The problem was approached in a manner in which it had not been attacked before, the inventor utilizing the experience of the makers with Truffault-Hartford shock absorbers, in which a friction joint is used to take up a sudden shock caused by road inequalities. In fact, there is a miniature shock absorbing mechanism located between the crank and the gearing which transmits the cranking movement to the crankshaft of the engine.

The safety crank is illustrated in Fig. 3, indicating its strength and showing the nut used to adjust the pressure between the spring plunger pawl rigidly fastened to the crank and the stationary ratchet which is attached to a gear reduction box. If the crank is turned in the usual manner, it turns a friction disc mounted on a shaft which transmits the motion to the gearwheel in the box where it is reduced to a low gear. The friction between the disc attached to the crank and the one mounted on the secondary shaft is sufficient to turn over the engine, but if back-firing should occur and the tendency to back-kick manifest itself a spring plunger mounted in the ratchet housing positively holds ratchet and pawl in contact, thus braking the torque exerted on the crank. The latter is thereby held in place, and owing to the minimum amount of friction between the discs, the secondary disc fails to turn the primary one—the one attached to the crank—around and slips without transmitting the work of the engine to the crank. In this manner back-kicks are avoided.

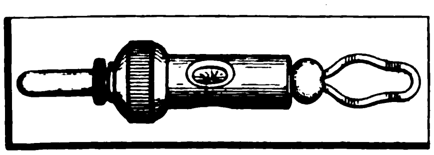

Fig. 4—Phelps spark plug attachment to detect the cylinders that miss fire.

The combination of the oilless friction discs and the low-gear transmission also results in easy cranking, avoiding all the dangers accompanying the lifting of a heavy weight, which may result in internal injuries even more serious than a broken arm.

Spark Plug Trouble Finder

METHODS of locating a misfiring plug are numerous, and as a rule the most troublesome ways of doing this work are the least efficient. Automobilists who have gone through the embryonic stage of their career will appreciate a device that will help them to find out, in a short time, which of the four or six plugs refuses to work without getting their hands covered with dirt, soot and receiving an electric shock at times.

Among the several appliances now on the market for the purpose mentioned the Phelps trouble finder, shown in Fig. 4, is fastened to the terminal with the looped end, the other end being connected to the source of electricity, and when the plug works properly a spark will appear between the two points inside the trouble finder, while if the cause of misfire lies in the magneto or coil no spark will appear. This accessory is manufactured by the New England Equipment Company, Boston, Mass.

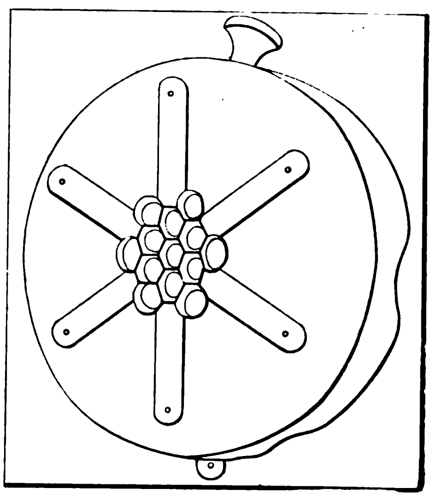

Fig. 5—Receiver on the Auristophone, saving the automobile passenger from excessive vocal strains

Automobile Auristophone

The appliance so named and shown in Fig. 6 has been constructed with the object of increasing the comfort of the passengers, of a closed car, being either of the limousine, laudaulet or taxicab type. It is very unpleasant for a person riding in one of these comfortable machines to risk his safety whenever he wishes to give the chauffeur an order, but such a situation is hardly to be avoided if it is necessary for the passenger to put his head out of the window. Abstracting from the danger of such an undertaking, the point must be borne in mind that the noise of the street makes it impossible for the driver to hear and understand "his master's voice" unless the latter shout in a manner which must necessarily hurt his own gentlemanly feelings.

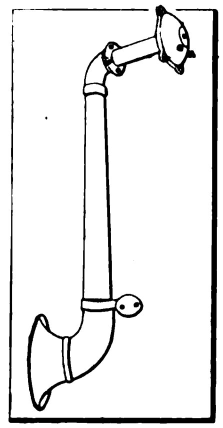

Fig. 6—The Auristophone, an electric sound transmitter

Speaking tubes have been installed to improve the situation and a further step in the forward direction presents itself in the form of the auristophone, which consists of a reproducer to be attached to the outlet of the tubing and one or two receivers installed at the other end of the line. The receiver is shown in Fig. 5. A set of three cells delivering a current at 6 volts is the source of power which helps to intensify the sound waves entering the receiver in the interior. By pressing a button on the receiver the circuit is closed and the receiver put in action, taking up and intensifying the sound waves, and then transmitting them, as electrical oscillations, to the megaphone, the top of which carries the reproducer. The latter translates the electrical waves again into sound waves. The megaphone and reproducer are so placed that the intensified sound strikes the ear of the chauffeur directly, none of the sound being lost in the process, so that the orders of the passengers are clearly heard despite the noise of the street.

While the regular set sold by the manufacturers, the H. G. Pape Electric & Manufacturing Company, of Buffalo, N. Y., comprises one receiver and one reproducer, they also market a set permitting of the installation of another system in which two receivers are used and more sound waves are taken up and transmitted to the driver's ear.

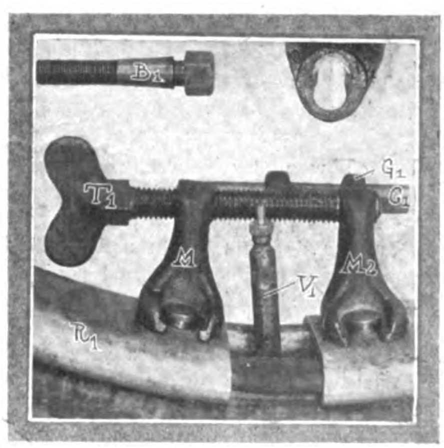

Fig. 7—The special rust-breaking tool, a feature of the Detroit demountable rim

Seen in the Show Window

MANUFACTURERS of assembled automobiles, if they feel determined to be successful in their business, turn their attention toward the quality of the material which is used in the makeup of the cars which their factories turn out. Unless such manufactories assemble high-class parts into a harmonious unit, all aiming at the target of success will remain futile, and time and money of the men directing the undertaking will be wasted. A good motor is the soul of the automobile, taking a good one for consideration, but to imprison it in a poorly made chassis, having low-grade axles and wheels means to throw pearls before the swine. The parts mentioned, to have inherent quality, must be the result of standardized methods of production and the use of up-to-date, reliable machine tools, and our illustration (BC) of the rear axle made by the American Ball Bearing Company, of Cleveland, Ohio, hints at strength and quality incorporated in the product by the manufacturing process.

THERE is no way of avoiding depreciation in a machine, but the endeavor of the engineer is to concentrate it on as few parts thereof as possible, which in almost every case means a saving. While this process necessitates the use of high-grade material for the parts which thus take most of the strain, and this increases the first cost and maintenance of the part ·oper, the machine as a whole profits ·reby and the owner saves in the long ı. Automobiles, as they travel over ·mmon roads, would be bound to depre-ıate rapidly, were it not for the springs that are made to take by far most of the shocks and strains created by these conditions. At (BD) is shown the Radial Elliptic Spring, this being of the three-·er elliptic type now generally used ·ear suspension of an automobile. n City Spring Works, Twentieth anta Fe Railway, Chicago, are

·—Two types of Lunkenheimer sight-feed lubricators

BF—Illustrating a strong and simple form of universal joint

BG—Illustrating the Racine Leather-Tread Horse-Shoe Tire

BH—The Indian spark plug, made of Indian pipestone

there is a sight feed installed on the dash of his car. Two types of sight-feed lubricators are shown at (BE), both being made by the Lunkenheimer Company, of Cincinnati, Ohio. They are equipped with check balls and baffle caps, which insures proper working of the devices at all times, since because of the two features mentioned it is impossible for cylinder back-pressure to fill and stop up the sight feeds.

A CHAIN is no stronger than its weakest link, and considering the fact that an automobile driveshaft serves in a capacity somewhat similar to that of a driving chain, it stands to reason that the universal joint connecting this shaft with the rest of the transmission system must be very strong in order to withstand the strain put upon it by the hard work it has to do. A strong and simple form of universal joint is seen in the illustration (BF) and attention is called to the special type of grease cap, the thread of which has six turns and which is sure to stay in place and keep the part it covers well lubricated. This is the style A of universal joint made by Blood Brothers Machine Company, Kalamazoo, Mich.

RUBBER being an expensive material, numerous attempts are being made to replace it in tires, at least to some extent, and the use of a leather tread on a shoe built of Sea Island cotton layers frictioned with Para rubber is the practice of making automobile tires at the factory of the Racine Auto Tire Company, Racine, Wis. The tire is illustrated at (BG) and shows the anti-skid tread made of chrome-tanned leather, four strata of which are superimposed and united by three layers of pure up-river Para rubber. Rivets driven through the two top layers of the leather insure a non-skid effect, and from this peculiar construction has been derived the name Racine Horse-Shoe Tire.

INSULATING materials used in spark plugs must have a high electrical resistance, and experimenting with several materials has led the makers of the Indian (BH) to the utilization of Indian pipestone specially treated by a chemical process. In addition to this feature, the plug is said to be damaged neither by excessive heat nor cold, nor will it retain soot, and the spark plug is guaranteed to last five years by the Templeton-Barrett Company, whose factory is at Marinette, Wis., while the Gotshall-Bailey Sales Company, of 1254 Michigan Avenue, Chicago, are sole distributors for this product.

Vol. XXV. New York—Thursday, August 3, 1911—Chicago No. 5

THE AUTOMOBILE

What It Costs to Run a Truck

Total Expense Based Upon Years of Service

In this article, the fourth in the series showing the cost of operation and maintenance of automobile trucks, the total cost per wagon-mile is treated from the same broad viewpoint as in the previous articles. Both gasoline and electric wagons are considered and various types of each, representing hundreds of cars, followed through several years of actual service. The figures show that the average gasoline truck can carry freight at six cents per ton-mile and that a corresponding service can be performed by electric trucks at seven cents. Excessive speed is the worst element of waste of both varieties of cars.

COST of automobile truck operation and maintenance may be divided into four classes, excluding the wages of the crews from consideration. These classes are as follows: Supplies, including parts and everything that is required to keep trucks in commission; second—gasoline, current and oil; third—wages of garage employees or the costs of incidental and ordinary repairs and work in garages; fourth—tires.

In previous issues of The Automobile, each of the latter three items has been treated at considerable length and the matter of supplies has been gone into briefly in several connections with the main subject.

In the following article the total cost of operation of trucks without reference to wages of crews or the rental charges of garages will be treated from the same wide and liberal view-

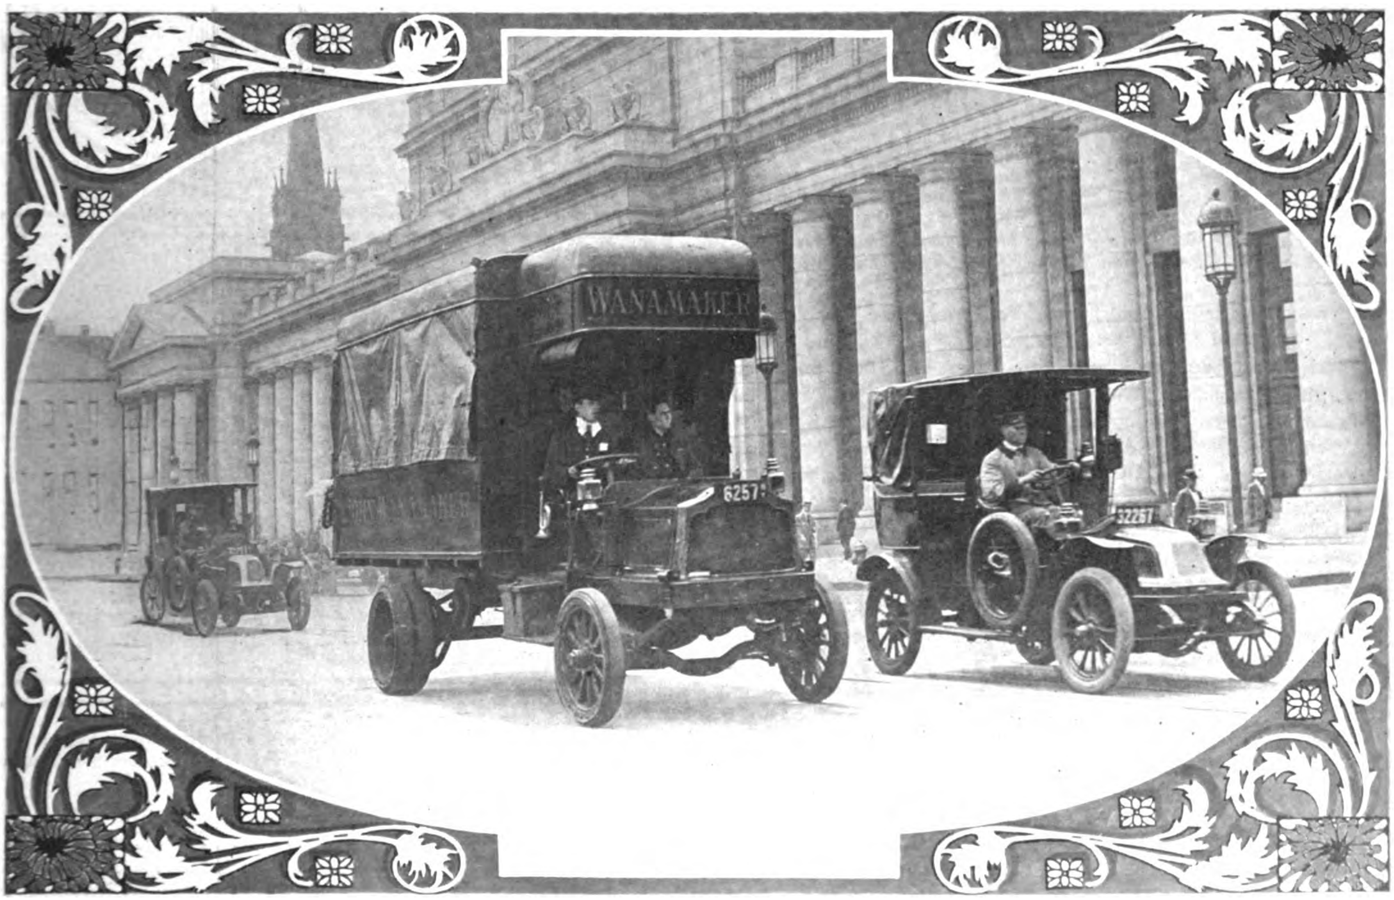

FIG. 1—PASSENGER AND FREIGHT MECHANICALLY PROPELLED VEHICLES LEAVING THE PENNSYLVANIA STATION

point as has been used in foregoing articles referred to above.

Taking the wagon-mile as the unit for comparison and computation it has been found that it costs 1.772 cents to operate a truck one mile for tires. This figure is based upon the experience of 1,000 single solid tires in actual business service under varied and typical conditions and taking the tires from the moment they were first installed until their worn remnants were consigned to the scrap heap.

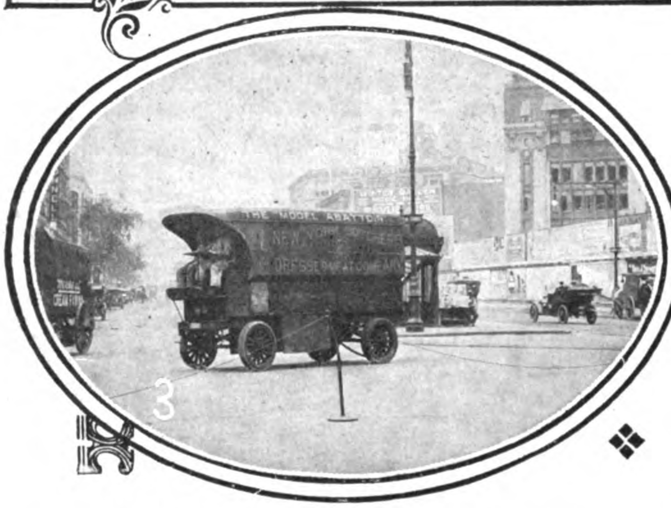

Fig. 2—Gasoline truck with four tons of merchandise
Fig. 3—The Model Abattoir uses electric trucks in its delivery service

The automobiles upon which they were used are small trucks ranging in capacity from one ton to three tons in burden bearing ability and including both gasoline and electric vehicles of numerous standard makes. The range of tire costs was from something less than 1 cent per wagon-mile to slightly over 5 cents, with the average figure as stated above.

It was proven that excessive speed is by far the greatest element of loss in respect to tire costs and that the size of the truck has little to do with the wear and tear on tires as long as an economical rate of speed was pursued. The average tire mileage delivered was almost 12,000 and the original cost in the neighborhood of $50.

The rate of speed ranged from about 10 miles an hour to more than twenty miles, with the average about 12.

There proved to be practically no difference in cost for tires used on both electric and gasoline cars, the extra weight of the electrics being counterbalanced in tire wear by the more severe engine strains placed upon the tires by the gasoline cars.

As to fuel and oil for the gasoline cars, the experience with all the trucks of this type used in this illustration showed that the cost of gasoline was 1.74 cents per wagon-mile and that oil and grease made up another item of .608 cent, thus giving a total of 2.348 cents for fuel and oil for each wagon-mile made by the gasoline cars under observation, the number of which was in excess of 300.

Considering the corresponding item with regard to electric trucks, the figures covering a period of four years show that battery and current costs and the expense for lubrication totaled 6.512 cents per wagon-mile. Roughly speaking this item may be divided into three heads as indicated. The approximate figures for each item are as follows: Battery, 3 cents per wagon-mile; current, 3 1-2 cents per wagon-mile, and oil, grease, etc., about 1 3-4 mills per wagon-mile.

In each case the average for garage work, wages of garage employees and ordinary maintenance and repair was a little over 3 cents per wagon-mile, the actual figure being 3.1 cents.

Battery costs follow the size of the truck very closely, but there appears to be a wide difference in the item of expense for current. For instance, the exhaustive tabulations show that the cost for current to run a two-ton electric truck is not much more than it is to operate a truck of half its size. Lubrication cost proportionately more for a big truck than it does for a small one.

The gasoline wagons of the same period used a certain amount of fuel which may be accurately gauged by the horsepower of the various cars involved. Thus the wagon-mile cost of gasoline cars, considering the three items, has been:

Fig. 4—Small parcels being delivered by a Brush delivery wagon
Fig. 5—Autocar express delivery wagon used for quick transportation of perishable goods

Tires	.01772
Oil and gasoline	.02348
Garage work	.03100
Total	.07220

To this must be added the cost of supplies of every kind not included among the above items, the parts that are used for replacements and all material and merchandise as well as extraordinary repairs requiring unusual expense such as overhaul.

A broad experience of four years shows this item to be large and exceedingly important in figuring the total cost of truck operation, and in the cars used in this illustration it amounted to an average figure of 6.06 per wagon-mile. Thus the total cost of operation of gasoline trucks proved to be 13.28 cents per wagon-mile or a shade less than 6 cents per ton-mile.

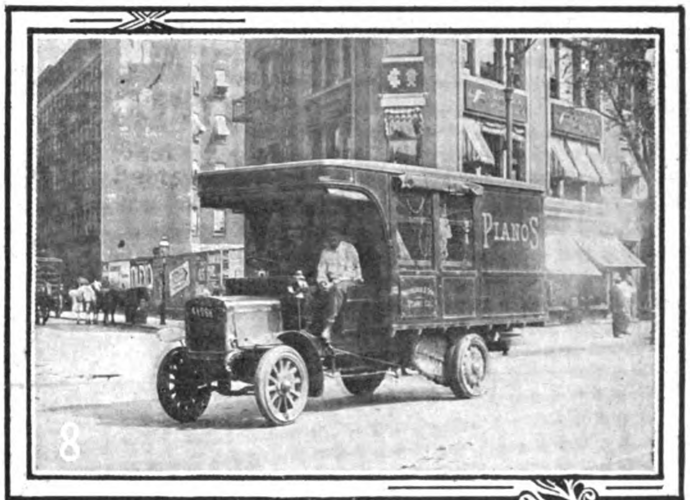
It should be noted that the cost of operating gasoline trucks has been very materially reduced in recent years. A supplementary tabulation arranged from the data covering cars used prior to 1908 shows that operative costs were much higher before the gasoline truck reached its present stage.

Considering the electric trucks in the same way as the foregoing, the figures show the cost per wagon-mile as follows:

Tires	.01772
Battery	.02984
Current	.03356
Lubrication	.00172
Garage work	.03100
Supplies	.02366
Total	.13750

It will be noted that the item for supplies is vastly greater for the gasoline cars than it is for the electrics and this is explained by the fact that the cost of battery replacements and repairs are not included in that classification but are considered as a separate item.

In a comparative way it may be said that the cost of operation is about the same for both gasoline and electric trucks, with the balance favoring the gasoline cars. The difference is considerably greater to the advantage of the gasoline trucks when the computation is reduced to a basis of ton-miles. The tabulations show that the cost is about 7 cents per ton-mile by electric trucks and a trifle under 6 cents by gasoline wagons.



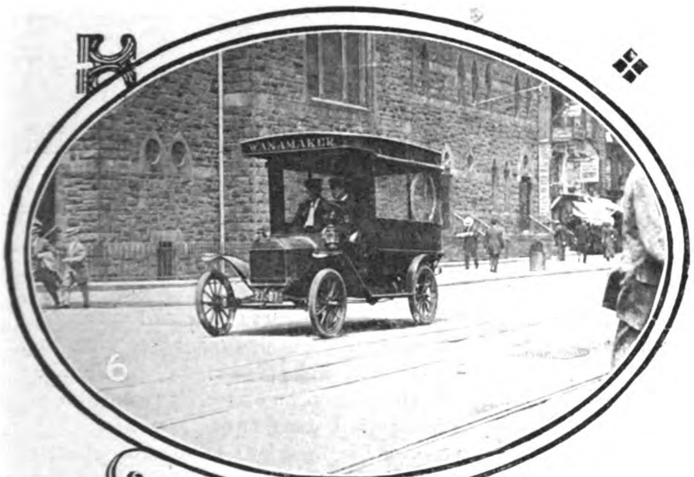


Fig. 6—Large department stores employ a fleet of small wagons for express delivery
Fig. 7—Sampson truck with box type of closed body used for heavy work by paint manufacturers

Fig. 8—Commer truck with chain cases handling pianos in New York
Fig. 9—Electric wagons have a large field in the brewing business

On a basis of 10,000 miles a year, the actual cost of operating and maintaining a typical gasoline truck would be $1,328, and for this price the truck would deliver 22,100 ton-miles of freight service. With the electrics delivering the same number of wagon miles per year the cost would be $1,375, and the ton-mileage would approximate 19,650.

Thus the gasoline truck delivers the same number of wagon-miles as the electric truck for $47 less a year, and, at the same time, on account of the larger size of the gasoline trucks used in this illustration, the ton-mileage is greater for that type of wagon by 2,450 ton-miles per year.

The best types of gasoline cars were operated at 12 cents per wagon-mile as a minimum yearly figure. These cars are modern trucks of three-ton capacity, and for a single year the ton-mileage figure has been as low as 4 cents. Other types of three-ton gasoline trucks have averaged 4 1-2 cents per ton-mile and those of smaller size run to larger figures in the ton-mile computation.

Referring to the experience with the earlier gasoline trucks, it may be said that the excessive operative costs were due solely to mechanical crudities which have been corrected in large measure in the wagons of current use. Some of these ran as high as 15 cents a ton-mile and delivered a comparatively small number of the revenue-producing units. This made a bad showing for gasoline-operated automobiles in comparison with the electrics and

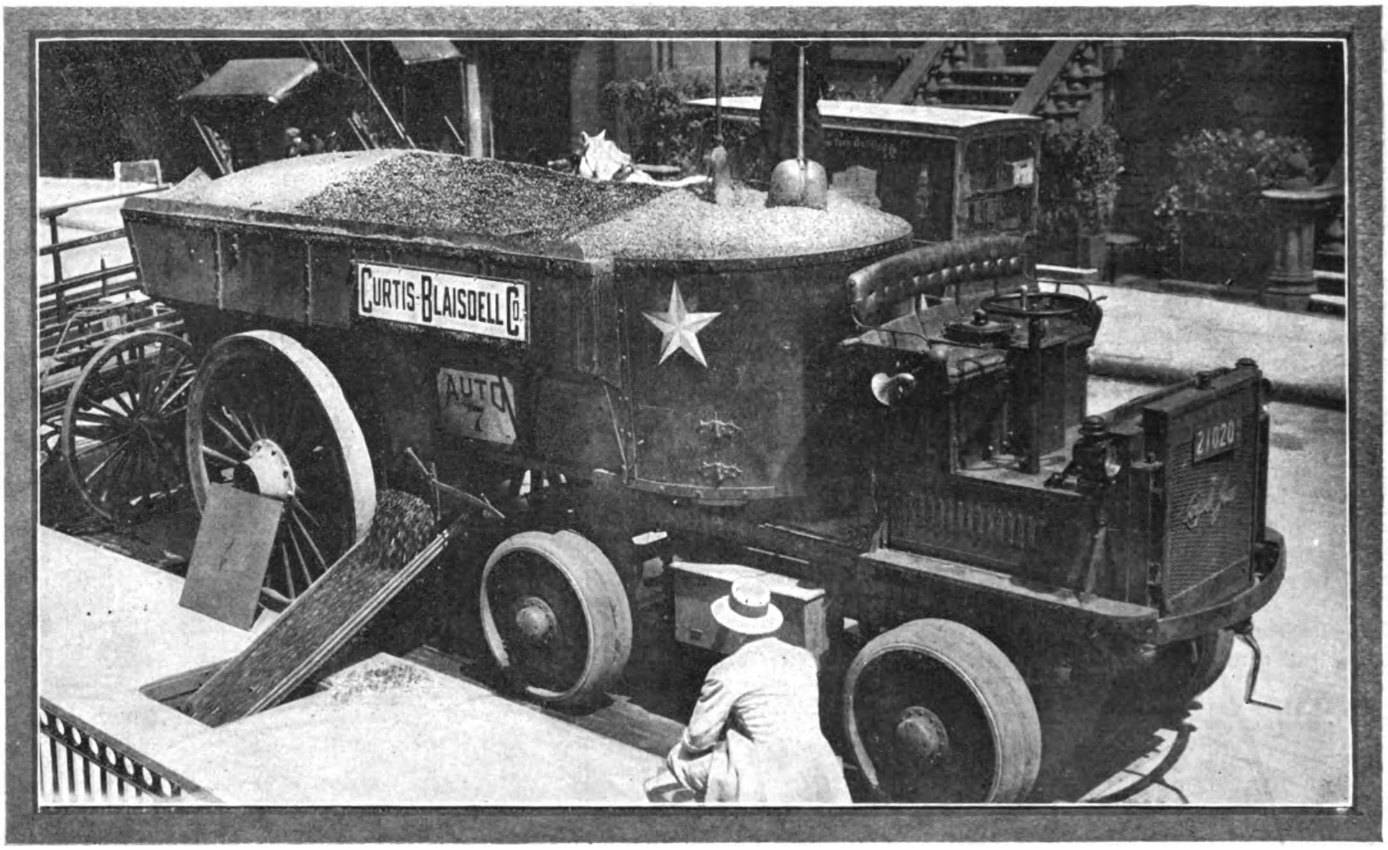

Fig. 10—Couple-gear gasoline electric truck delivering ten tons of coal

for a time checked the extension of the lines of gasoline trucks.

The situation touching the electric truck operative costs is set forth in much detail in the data at hand. The best figures for one-ton trucks are about 8 cents, while the most economical of the two-ton types cost about 9 cents to operate and maintain. The two-ton electric truck stands out sharply as the more economical to operate on a ton-mile basis, as the total cost in this respect for the best types of electric trucks observed was 4 1-2 cents per ton-mile for year after year. They were no harder on tires, used very little more current and delivered twice the ton-mileage shown by the smaller vehicles.

As an illustration. On a basis of 9 cents, the cost of operating a two-ton electric truck for 10,000 miles in a year would be $900, delivering 20,000 ton-miles without overloading the wagon. The best of the smaller trucks cost $800 to deliver 10,000 ton-miles. Without regarding garage rentals and the wages of the crews and assuming that the gross revenue from this freighting would be 10 cents a ton-mile, the revenue from the larger truck would be $2,000 gross or $1,100 net in the course of a year. Of course the revenue from hauling is probably much more than 10 cents per ton-mile.

Turning back to the gasoline situation as above, the basis of computation of 10 cents per ton-mile would make the average revenue of the gasoline truck $245 greater than that of the electric at a cost of $47 less per year, thus indicating an economy in operation of the gasoline over the electric of $292 a year.

However, these figures may be a trifle unjust to the electric because the cost figures of the ancient and expensive gasoline trucks were eliminated and all the data at hand were used with reference to the electrics.

Applying the pruning knife to some of the worst specimens of the electrics included in the data, it is found that the modern cost figures would probably be made more nearly approximate if a certain series of old one-ton trucks could be eliminated in the same way as the wasteful types of gasoline cars. For instance, a few years ago there were about 100 trucks of this kind in service, the data for which constitute a part of the material at hand. These trucks cost 23 cents a ton-mile to operate for two years and by cutting them out of the calculations the result probably leaves the total figures very close to the actual present cost of truck operation. While the gasoline cars eliminated numbered only a few, practically all of which are now out of service, the electrics under the knife are still in service to a considerable extent. The elision leaves the wagon-mile cost of operation at 13 1-6 cents and makes the ton-mile cost under 7 cents.

If there is anything typical about the kinds of one-ton electric trucks that are included in the tabulations, it would appear that this size of wagon is not suited to competition with cars of double its size and being comparatively uneconomical in operation must give way to the larger cars.

But the most astonishing thing shown in the figures covering all the stages and phases of truck operation is the steady growth of economy in cost. While the price of freight automobiles remains substantially level and has done so for the whole period covered, the quality and mechanical excellence of the cars has increased. Dollar for dollar there is more value in the cars of the present than there was in the cars of the past, no matter what the price.

This increase in efficiency and economy may be shown briefly as follows:

In 1907 the gross cost per wagon-mile was 15.8 cents, based upon all the trucks used in this illustration. The gasoline trucks cost 24 cents per wagon-mile and the electrics 14.655 cents. The following year the wagon-mile cost was reduced to 15.09 cents, in 1909 to 14.17 cents and last year it came down to 13.56 cents.

This was accomplished in various ways, one of which was, of course, to eliminate the gasoline-eating and current-wasting machines and to substitute in their places cars typical of the state of the art. In order to show just what a potent cause in behalf of economy such practice proved to be, it is illuminating to know that the general proportion of cost was not disturbed by reason of the arbitrary culling out of the non-economical cars, resorted to in this article in an effort to approximate actual present costs.

With these eliminations the 1907 figures were 13.98 cents per

Fig. 11—Ice cream manufacturers are taking advantage of the new means of locomotion

wagon-mile; 1908, 13.89; 1909, 13.75, and 1910, 13.13. It is likely to be still further reduced in 1911 by reason of equalizing the efficiency of tires, so as to get uniform mileage out of complete sets, by enlarging the carrying capacity of electric trucks, by the substitution of small gasoline cars for the electrics of corresponding size and by a stern and rigid check on excessive speed.

One of the striking things about the situation is the larger mileage achieved by the automobile truck in 1910, compared with former years. In 1907 the general wagon-mileage was under 9,000, while in 1908 it was 500 miles greater. In 1909 the trucks made 10,300 miles and last year the figures were just short of 12,000 miles. Naturally these high figures are not general averages, but they do represent the performance of the best classes of trucks, some of them as much as four years old.

Tour to Water Gap Is Delightful

Fine Roads and Beautiful Scenery on Route

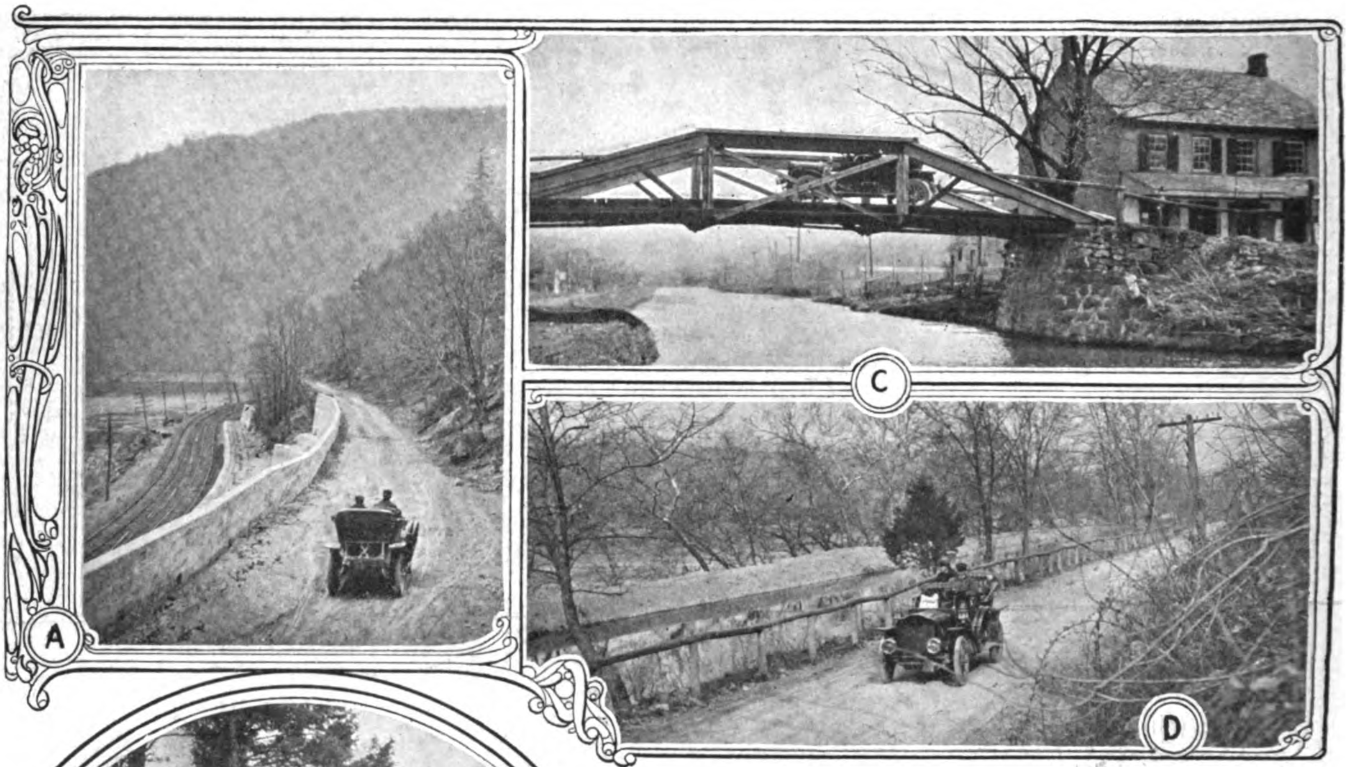
Among the finest two-day runs afforded in the East is the tour from New York to Delaware Water Gap and return. This route carries the tourist through the hills of northeast Jersey and southeast New York, past Tuxedo and through the beautiful country lying to the west. The way reaches Port Jervis and enters the picturesque country near the Gap over smooth, well-kept roads, bringing up at the chasm in the hills through which the Delaware River flows down to the sea. The return trip takes the party down stream, crossing into Jersey and mounting the Schooleys on the way to Morristown.

ONE of the puzzling questions that constantly confront the car owner is: Where shall we tour? and it is answered in so many ways and so differently that the owner is often more confused by the advice he receives than helped by the suggestions offered. If he has tried the New England hills and the Connecticut, Long Island or Jersey shores, or even if he has not, he might try a run to Delaware Water Gap some Saturday and return through Jersey the next day.

He will not be disappointed in the roads, for they are among the best on this side of the world. There will be no hardships from one end of the trip to the other and the scenic beauties compare favorably with anything to be seen in this part of the country. In fact, there are spots along the way that rival in grace and beauty any in the world. There will not be a monotonous moment during the trip if diversity of scene and calm enjoyment of nature's smile have the power to charm.

The trip is not arduous in any way, the roads being well-nigh perfect and the mileage moderate.

Starting from New York City in the mid-forenoon the tourists proceed to the Fort Lee Ferry across the Hudson at One Hundred and Thirtieth street. By following Route 18 of Volume 3 of the Blue Book the landing is made on the Jersey shore at Edgewater which lies at the foot of the Palisades. There is a long, stiff climb to the summit, but the hill is not so steep as



A—Where the Delaware breaks through the granite hills
B—On the road to Milford town through the woods
C—One of the many bridges that span the canal paralleling the Delaware
D—Leaving Port Jervis on typical road of the section

to cause trouble if a little care is devoted to shifting gears. Fort Lee village lies on top of the hill, from which on a clear day a view of Washington Heights and the full sweep of the North River waterfront of the metropolis may be had. This view will give a better idea of the immensity of New York City than the most perfervid descriptive pamphlet, no matter how voluminous.

After crossing the backbone of the ridge the way descends to Overpeck Creek, and then crossing the Hackensack River just before reaching Hackensack, the party passes through that village on the way to Arcola. The old mill that has done service for generations is one of the interesting sights to be seen here.

The road, splendid macadam, continues through Hohokus to Suffern, which is just across the New York State line. Here the road divides, one branch following up to the Hudson River at West Point and the other bearing straight ahead to the crossing of the Ramapo River, thence to Ramapo and Sloatsburg, reaching Tuxedo about two hours from the start. Tuxedo is a resort for New York millionaires and is considered to be one of the most magnificently improved suburbs in the world.

From Tuxedo the way is through Southfield, Monroe, Chester and Goshen. From Goshen to Port Jervis the road is through one of the richest agricultural sections of New York. The country is varied in aspect, rich and rolling and with enough timber to afford a wealth of color and shadow to the landscape.

This road passes through Denton and Statehill station over Shawangunk mountain, descending a long grade with several interesting turns and sharp curves. A short distance farther the road winds through the village of Tri-States and reaches Port Jervis at Front and Pike streets.

The run so far has been 76.4 miles, a nice easy jaunt of four hours. There are a number of excellent places at Port Jervis where the party may have luncheon, after which the rest of the run to Delaware Water Gap may be finished with ease through the most picturesque section of the hill country.

Route 341 of the Blue Book is the favorite way to pursue from Port Jervis to the Gap and passes over fine roads, the base of which is shale. The road follows down the Delaware River Valley and is noted as being one of the favorite runs for automobilists. It is supremely picturesque and must be seen to be appreciated.

Crossing the Delaware into Pennsylvania the way leads to Milford through a scene of natural beauty that would be hard to equal on a Summer day, and following west and south it crosses Sawkill Creek. The woods are a magnificent feature of this stage of the journey, although every turn of the road develops some new natural beauties. At Dingman's Ferry and along the way leading to it there are some delightful waterfalls to center attention. The creek is crossed by a modern iron bridge, but the ruins of the old bridge and ferry form an interesting point.

Egypt Hills, Bushkill station, Shoonmaker, Echo Lake are passed in order and the party reaches Shawnee-on-Delaware in about two hours' leisurely run from Port Jervis, the mileage being 36.3.

The rest of the way is largely up grade to the North Water Gap postoffice, where the hill road crossing Cherry Creek brings the tourists to the end of their journey.

E—Stopping at a wayside inn high in the hills
F—After leaving Shawnee in the final run of the first day
G—Typical scene in the mountains west of Port Jervis
H—In the heart of the Delaware Water Gap

There are numerous hotels at Delaware Water Gap, several of which are said to be of first-rate class.

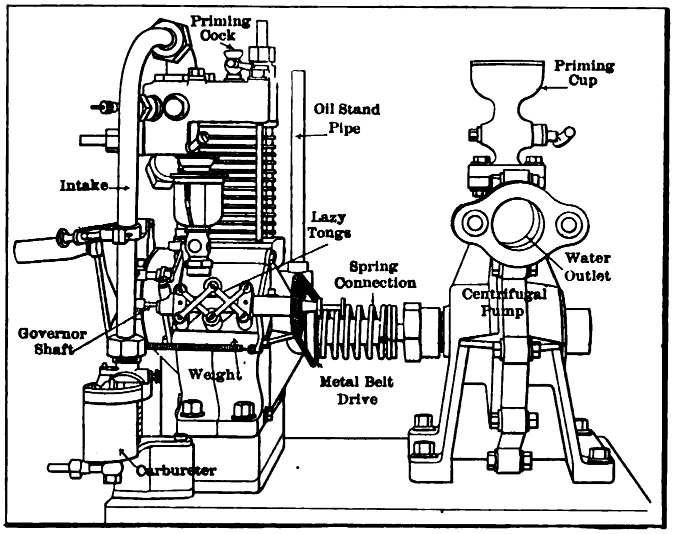
The return trip through New Jersey is delightful and interesting but entirely different from the outward-bound journey. Following Route 332 out of Delaware Water Gap the run to Morristown, N. J., is only 50.7 miles. Leaving the Gap the party trends southward along the Delaware River to the old-fashioned cable ferry, where the automobile is embarked upon a flat boat and pulled across the stream to Myers Ferry, N. J. From the landing the way rises gradually and then sharply, passing Hackettstown. The towns along the way south of the Gap are: Portland, the Ferry, Delaware, Bridgeville, Butzville, Townsbury, Danville and Meadow Station.

Continuing nearly straight ahead into Main street, Hackettstown, the party passes the Soldiers' Monument and crosses the Musconetcong, where the ascent of Schooley's Mountain commences. At the crest of this beautiful hill is a wonderful view of the Musconetcong and German valleys. This section used to be one of the leading resort districts of New Jersey, and the reason for its not maintaining that rank is difficult to understand. The descent is also sharp and complicated with a dangerous horseshoe curve. The grade is about a mile and a half in length and the roads on both sides of the mountain have been finely improved, which adds materially to the pleasure of the trip and makes for safety of the tourists. Reaching German Valley station the road turns left after crossing the stone bridge and proceeds to Chester, Mendham and into Morristown. If a late start was made from Delaware Water Gap, it may be well to have luncheon at Morristown, where there are a number of creditable hotels. This little city has an immortal place in history as the headquarters of Washington in one of his Jersey campaigns.

From Morristown to New York there are several fine routes, but the choice will probably fall upon Route 126 on account of the two fine, easy climbs over the Watchung Mountains over splendidly improved roads. This route is via Florham Park and Newark and is 31.1 miles in length, entering the metropolis by the Weehawken Ferry at Forty-second street. The route takes the party through Madison, Florham Park, mounting a small hill and passing across the Passaic. Then comes the climb over the Watchungs, beginning with a long, steep grade across the first range and then, after a dip, commencing the climb over the second barrier, which is accomplished by a gentle and smooth ascent.

From there into South Orange the road sinks away smoothly into the plain and reaches Newark via Central avenue and Washington street. The way to New York through the New Jersey metropolis follows Bridge street, crossing the Passaic to the new tarred macadam road connecting with Hudson Boulevard, Morgan street, Bull's Ferry road, Third street, to the Weehawken Ferry.

The entire distance of the return trip is 81.8 miles, and for the whole journey out and back 197.9 miles. There is scarcely a mile of the way that is not well improved and well maintained, and the whole trip ought not to cause a moment's uneasiness to the automobilist. Garages and tire stations are frequent throughout the route, but with the fine roads there is little reason to anticipate needing them.



Illustrating one-horsepower air-cooled gasoline motor driving a direct-connected centrifugal pump

Direct-Connected Motor and Pump

The greatest efficiency possible is always secured by means of direct drive between the power plant and the driven piece of machinery. Where direct connection is possible the wear and tear of bearings and gearing is done away with, thus reducing the cost of up-keep.

THE accompanying illustration will give an example of how a pump may be connected directly to a gasoline motor. Of course where a reciprocating pump is used the only way possible to secure a direct drive is by having an engine with an opposed water cylinder. The centrifugal pump, as shown in the cut, can be connected directly to the extended crankshaft of the motor, and is driven at the same number of revolutions per minute as the gasoline motor.

The noticeable features in this plant are the spring connection between the motor and the pump and the governor on the motor. The spring connection is a safety device. In case the pump should, for any reason, become clogged so that it is jammed, the spring joint will be broken instead of the shaft. The spring can be easily relaxed, while to replace the shaft would be a very costly proceeding, not to mention the fact that many other parts may be broken.

The governor is of the centrifugal type. It is driven by a wire belt off the crankshaft. As the speed of the motor rises above normal, the weights on the joints of the lazy tongs are thrown out by centrifugal force, thus contracting the lazy tongs and moving the governor shaft which throttles the motor and cuts down the speed. As the speed is reduced the weights will fall back nearer to the axis and the throttle rod be pushed forward so that the throttle will be again opened and will remain so until the motor rises above normal speed.

The motor shown in the cut is a small one of one horsepower lubricated by gravity and splash and cooled by air. The pump and motor are assembled on the same base, which is so constructed as to bring the engine and pump shafts on the same level with each other. This gives a very light and compact little plant and one which may be used in a great variety of ways.

A pump of the centrifugal type is of great use in pumping water against a small head. When the back pressure runs up high there is a large percentage of the total efficiency lost in slip. This is true, of course, of the reciprocating pump as well, but not so much as in the case of the centrifugal type. This combination would be an ideal one if used for pumping the circulating water through a condenser in a steam yacht.

Concerning the American "30"

Latest Effort from the Plant at Indianapolis

It is worthy of note that the underslung idea is being continued by the maker of this car, and the idea here is to present a strictly mechanical version of the ramifications of the new product, showing the relations of components in the makeup of the car.

REFERENCE may be had to Fig. 1 for the general appearance of the new "30" model showing an underslung spring suspension and an enclosed type of body, with admittance to the tonneau on both sides, but the right side of the fore part of the body is blind, leaving room for the side

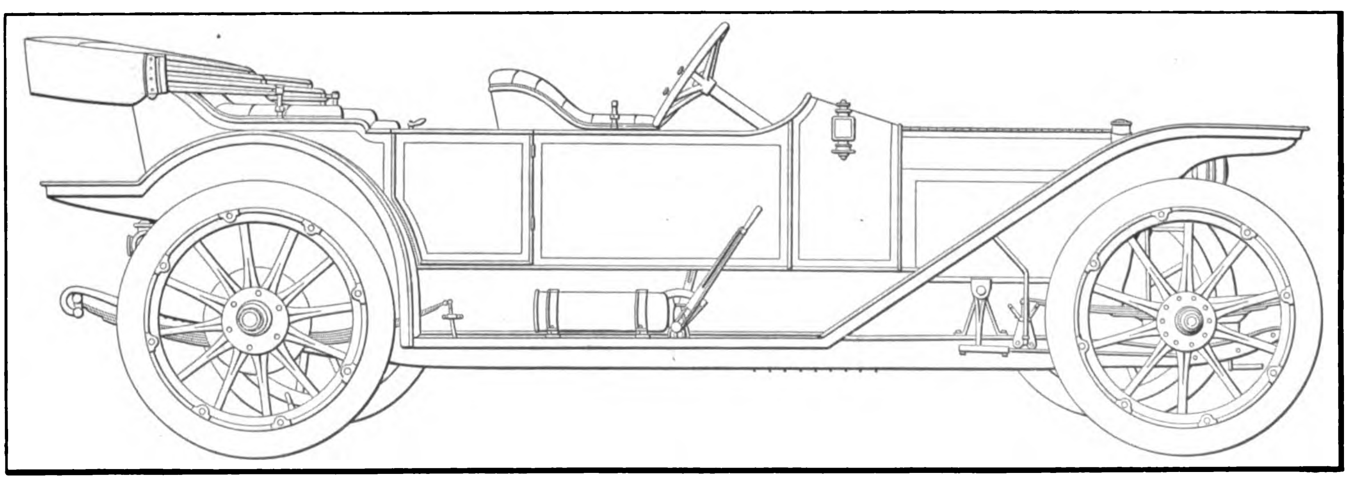


Fig. 1—General appearance of the new "30" American with flush-sided body, the front compartment being fitted with only one door

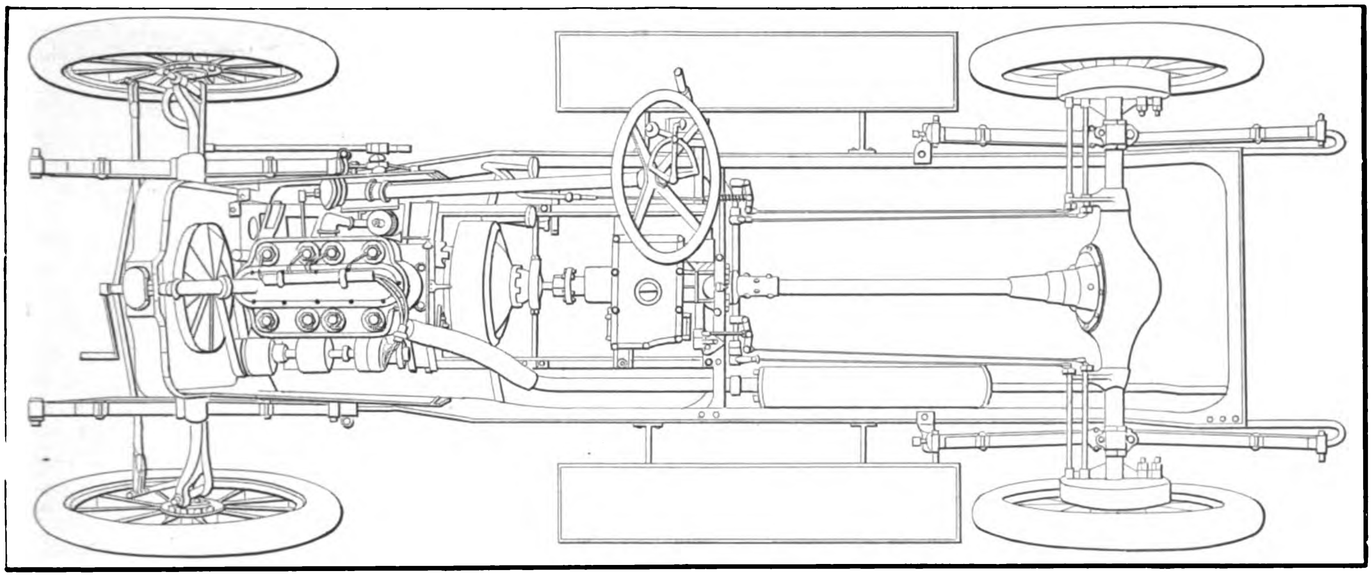

Fig. 2—Plan view of the "30" American chassis, showing the relation of the different parts

levers in the manner as shown, admittance being to the front seats by a fore-door on the left-hand side of the car. The general appearance of this model conforms to the broad idea of the American Motors Company, of Indianapolis, Ind., remembering, however, that a year's practice has brought about its refinements, leaving a certain indefinable something about the car as here shown that is not to be described in terms that fit the mechanical treatment of the car.

The plan of the chassis is shown in Fig. 2 with the radiator at the front of the motor placed far enough back on the side bars to clear the axle. The motor, including the transmission, is mounted on a sub-frame, making a substantial platform for the power plant, terminating in a crossbar back of the transmission gear, where a universal joint is placed at the extremity of the torsion tube, the latter enclosing the propellershaft so that the power of the motor is transmitted therefrom through the clutch housed in the flywheel, thence to the three-speed selective-transmission gear and to the propellershaft through the universal joint, thus delivering the power at the point of contact of the rear road wheels through the live rear axle. The scheme involved in the chassis construction for the purpose of taking advantage of the underslung plan of suspension is shown in Fig. 3.

How the Block Type of Four-Cylinder Motor Is Made

The four-cylinder block type motor is rated at thirty horsepower when the speed is 1,000 revolutions per minute. It is of the four-cycle type, water-cooled with four vertical cylinders, with a bore of 4 3-8 inches, and a stroke of 5 inches. The right-hand side of the motor is shown in Fig. 4 with the carbureter C1 in the mid-position, and the intake manifold leading up therefrom to a flanged orifice in the cylinder heads in the manner as shown. The motor is suspended by integral arms B and B1 reaching to the sub-frame, and the starting crank has its support S1 integral with the crankcase, although in the assembling of the chassis a crossbar at the front carries an outboard bearing lending stability to the starting crank support.

A cover C shown on this side of the motor, enclosing the valve mechanism, and the water manifold W is faced off and bolted to a finished face on the top of the block casting, which seems to be one of the most recent and approved ideas in water connection work. The bottom of the crankcase, which composes an oil reservoir, is provided with draincocks D and D1. Referring to Fig. 5 of the right-hand side of the motor the magneto M of the Bosch dual type is mounted on a ledge, taking its drive through a shaft terminating in a gear which meshes

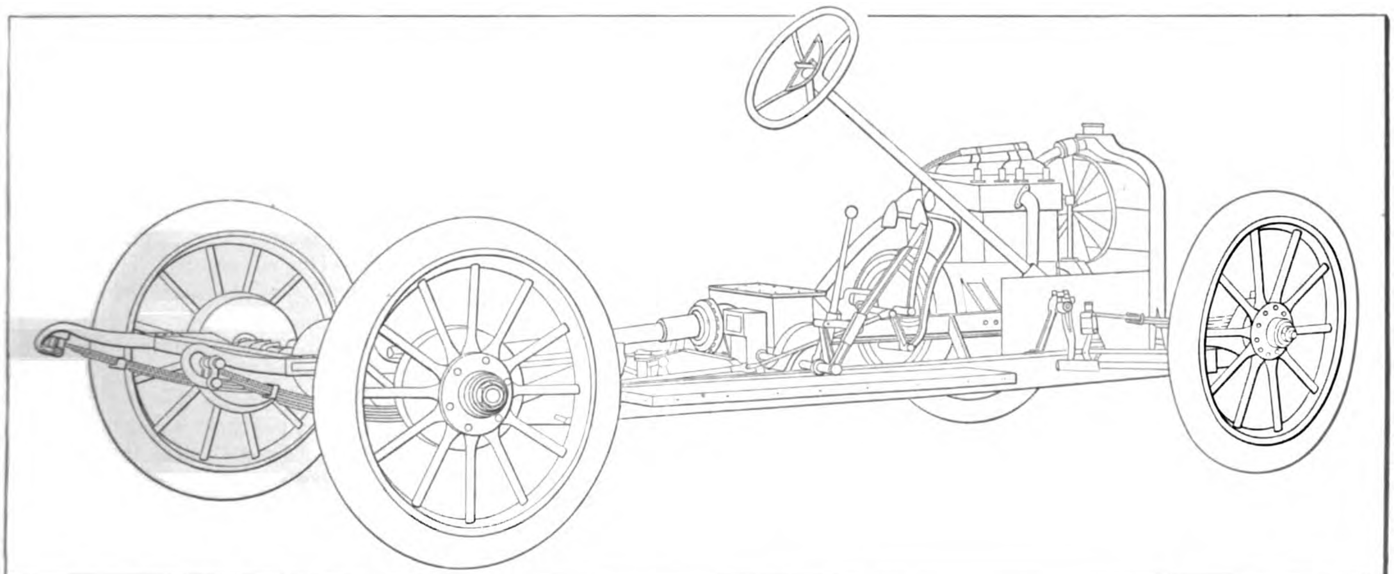

Fig. 3—Three-quarter view of the American chassis, showing the underslung feature, the method of suspension and the sub-frame, carrying the motor and transmission

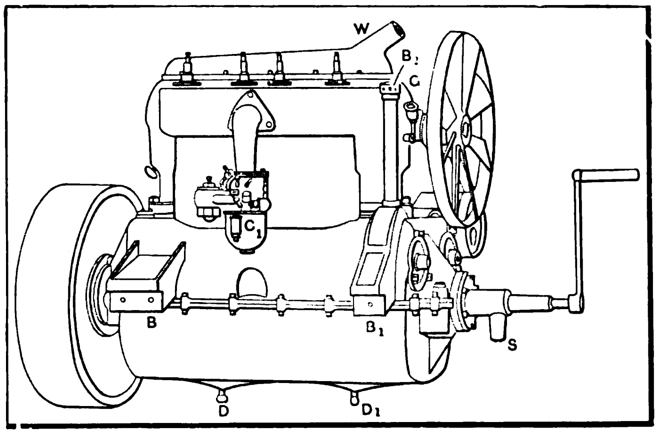

Fig. 4—Right-hand view of the motor, showing the short carbureter intake manifold and enclosed valves

in the half-time train, and the shaft is extended on through the water pump P furnishing power thereto and thence to the front of the motor with a pulley secured thereon, accommodating the belt B that drives the fan F1 as it is located between the radiator and the motor. Remembering that the motor is of the T-type with inlet and exhaust valves on opposite sides, it will be seen that a cover C is placed over the valve mechanisms on this side of the motor.

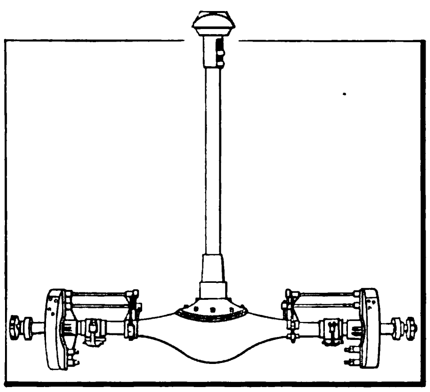

Fig. 6.—General appearance of the rear axle, showing the propeller tube casing with ball socket end

The exhaust manifold is cast integral with the cylinders and is therefore watercooled, terminating in the extension M1, which is bolted to the rear end of the cylinders and suitably connected to the exhaust pipe. The general appearance of the motor is very clean and some idea of the accessibility can be obtained from Fig. 3. The pistons and cylinders are ground and the former are fitted with four piston rings each. The timing gears are cut spiral with the object of eliminating any noise in this part of the mechanism. A system of splash oiling has been adopted, the various levels being maintained by means of internal webs. The bearings are large in diameter and are die-cast and scraped to fit.

The clutch is of the inverted cone type, the male member

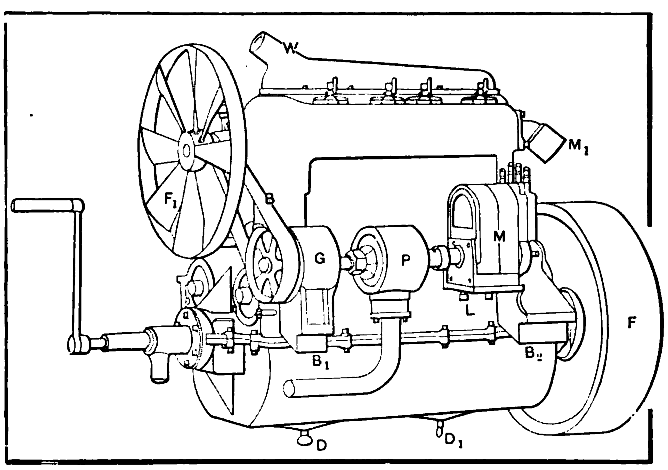

Fig. 5—Left-hand view of the motor, showing the arrangement of the magneto, pump and fan drive, together with the integral cast exhaust manifold

being faced with a suitable material to take the drive; spring plungers are placed under the surface to permit of easy engagement and in a measure elimate the shocks of starting. In order to make the operation of the clutch as light as possible the pedal arms have been designed with sufficient reduction to eliminate the fatigue in traffic driving. Between the clutch and the transmission is placed a universal joint to compensate for any bending action of the chassis, caused by inequalities of the road.

The transmission is located amidships and is easy of access by removing the floor boards under the driver's feet. The casing is of cast aluminum and is shown in Fig. 11. It will be noticed that the gear-shifting mechanism is entirely encased, thereby insuring efficient lubrication. The forward end of the housing is extended to accommodate annular ball bearings on which the shafts are carried. Three forward speeds and reverse are provided, and a gear-shifting lever is equipped with a ball handle so as to give the driver a good purchase. The gear wheels are made of special steel, heat-treated and tempered, and the same applies to the primary and secondary shafts. The direct drive is obtained on third speed. At the rear of the transmission is located the housing providing for a ball end thrust for the front end of the tubing which encloses the propeller shaft.

As will be seen by referring to Fig. 3, the front and rear ends of the springs are shackled, thereby eliminating the drive from the springs. The rear axle, shown in Fig. 6, is of the full-floating type, the tubular extension of the housing being fitted with ball bearings upon which the wheels are mounted. The housing is a pressed-steel forging, the front end being provided with a cover which receives the rear end of the propeller shaft casing. The jackshafts fit into the differential at one end, and the external ends are provided with dogs which drive the wheels through suitable slots cut in the hub.

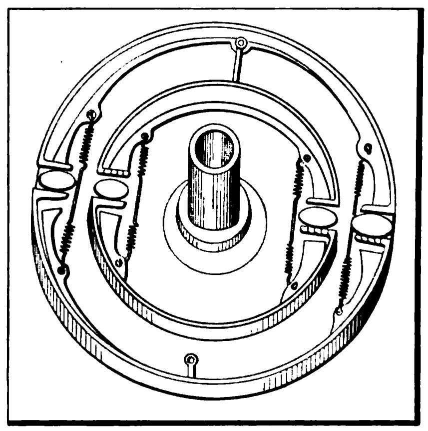

Fig. 7—View of the rear brake mechanism with the wheels removed

The differential assembly will be seen in Fig. 8. The crown wheel is attached to the exterior of the casing by means of bolts, and the casing is fitted at its two extremities with ball bearings which rest inside the axle casing. The brake drums which are attached to the rear wheels have two facings of different diameters to accommodate the two sets of brake-shoes shown in Fig. 7, both being of the internal expansion type.

Following along the lines of previous American practice, the wheels are of larger diameter, fitted with Q. D. demountable rims and 36 by 4-inch tires. The wheels are of the artillery type made of second-growth hickory with ten spokes front and twelve spokes rear.

The front axle shown in Fig. 9, is an I-section drop forging, with the cross-tie rod placed in front. The axle has a clearance off the ground of 10 3-4 inches, and is the lowest point of the car. The steering knuckles are fitted with roller bearings on which the front wheels run, and are attached to the main body of the axle by means of casehardened and ground pivot pins; they are fitted with grease cups to insure proper lubrication.

Both front and rear springs are of the semi-elliptic type, the method of suspension being shown in Fig. 3. The steering is of the irreversible worm-and-gear type, and is attached to the chassis frame by means of two feet, the drop arm which is fitted with a ball socket being placed exterior of the hood. The control levers are placed in the center of the steering wheel, which is 18 inches in diameter, and operate the control rods through two sets of bevel gearing which can be seen in Fig. 10.

The wheelbase is 118 inches, and the general equipment of the car includes top with dust cover and side curtains, five lamps, Prest-O-Lite tank and quick-demountable rims.

In addition to the "30" model, the 50-horsepower model will be continued in its present form with the exception of a few modifications, but in order to accommodate a six-passenger touring body a 140-inch wheelbase chassis may be had at the option of the purchaser.

It is proposed, in the near future, to place on the market still another model with practially the same features as mark the one herein described—for instance, the underslung frame—and the size of the motor will be 3 3-8 inches bore by 4 1-2 inches stroke.

With the coming demand for some provision of furnishing electric light for the lamps, the motor of the 30-horsepower model has been arranged for the installation of an electric-lighting outfit, the drive being taken from the pumpshaft by means of a belt. Considerable additions have been made recently to the size of the factory and it is the expectation of those connected with it to materially increase the output for the coming season, which will be largely due to the addition of the 30- and 20-horsepower models to the line.

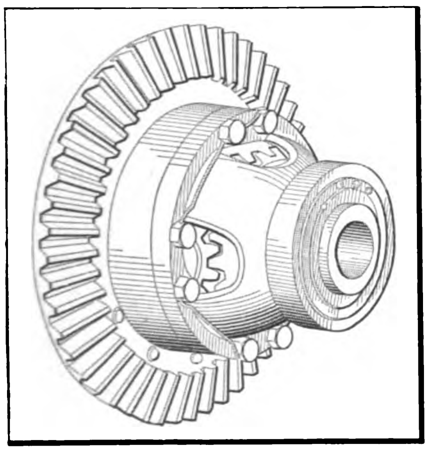

Fig. 8—Differential unit, showing how the crown wheel and ball-bearings are mounted on the cage

The price of the new "30" model is fixed at $2,250 with the style of body work as shown in Fig. 1, together with a complete equipment as above described. The bodies are made of sheet steel on a seasoned ash framework, and owing to the underslung chassis the passengers are brought lower than in the ordinary type, thereby causing the center of gravity to be considerably lowered. The advantage claimed for this in conjunction with the large wheels is that the turning-over effect is thereby decreased.

It Stands to Reason—

THAT an automobile that gives off a variety of odors is afflicted with a similar variety of disorders of its internal organs. It needs a stomachic.

THAT a chauffeur whose breath attars the air with alcohol fumes needs a permanent substitute.

THAT an indolent person is lacking in understanding—not liking work, he carelessly smears the body of his car with sticky matter which he has to clean off.

THAT a tyro in the automobile art should not be assigned the task of adjusting a carbureter.

THAT misery is the concomitant of undue haste in the selection of an automobile.

THAT the well-behaved motor of good antecedents usually shows its class by the quiet and business-like way it goes about its duties.

THAT the recurrent squeak that troubles the soul of the automobilist is doubtless the querulous plaint of some bearing that is athirst for lubricant.

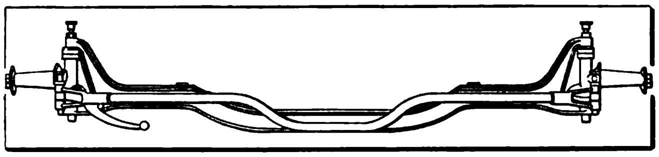

Fig. 9—View of the front axle, together with the connecting rod

THAT noise in a motor is in most instances a sign of low caste or improper feeding—or both.

THAT the motor that hums contentedly, like the bee that does likewise, is usually on the job.

THAT the buyer who takes nothing for granted, but insists upon being shown, need not necessarily be from Missouri.

THAT the owner of a tonneau is *persona grata* with the neighbors if he "comes across."

THAT the idea of reforming the maker of a poor product by taking it off his hands is not necessarily a good one.

THAT you are on the wrong scent when you are not open to conviction.

THAT each succeeding day brings the automobile nearer perfection; ambition, like a torrent, never looks back.

THAT a consistently bad performer is a good thing to avoid; it is well to profit by the folly of others.

THAT the car bought, with the assistance of a catalogue only, without a thorough examination, will in all likelihood soon be a "standing" advertisement of the buyer's gullibility.

THAT it is just as important to look into the antecedents of the car you are about to buy as it is to have a title "searched" before you invest in real estate.

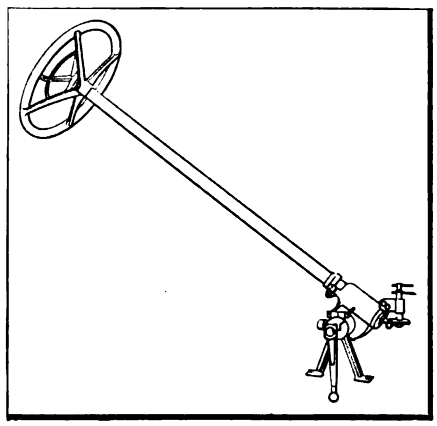

Fig. 10—Showing the steering gear together with the method of attachment and means of operating the control levers

THAT your membership in the Sons of the Revolution is no excuse for your being consistent and investing in an automobile of colonial design.

THAT fortune does not wait at any man's door; she must be sought and wooed before she will surrender.

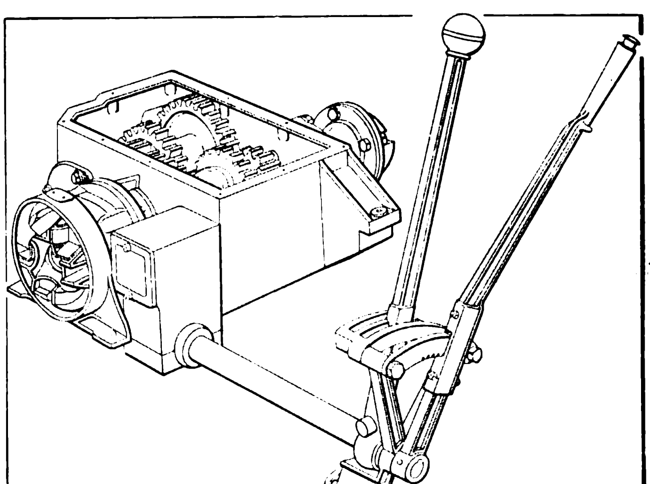

Fig. 11—General appearance of the transmission and levers and the ball-socket joint in which the front end of the propeller tube rests

A Detail that Designers Overlook

Like the poor, we always have the starting crank with us, and although self-starting devices are on the increase the old-fashioned starting apparatus has not yet been supplanted.

A GOOD deal depends upon the way that the starting handle of a car is made as to whether it will be an easy matter or not to turn the motor over for starting purposes. Preference is given by some to the short lever, and for small cars this should answer very well. But when it comes to a car of 40 horsepower, that in order to turn it at all the average driver has to have resource to the half-compression release, a long lever is preferable. The handle part, or the grip, as it might be called, has not undergone any material change from the time that the first car appeared on the road, perhaps with the exception that it is now made a permanent fitting, whereas in the olden days it was carried in the tool-box out of sight. If this part of the car's mechanism is to combine with the other parts in serving a useful purpose, the grip should be at least 5 inches long, and the part that comes in contact with the hand should be allowed to rotate freely on its axis. The mud and dust that is thrown up by the road wheels will clog the roller unless it is carried in a leather boot, and on most of the modern cars this is done. The end of the handle that is not attached to the lever should be at least 5 inches long, and on cars that require a lot of power to turn the motor over 6 inches is not too long. The end should be slightly lipped so that the hand will not slip off.

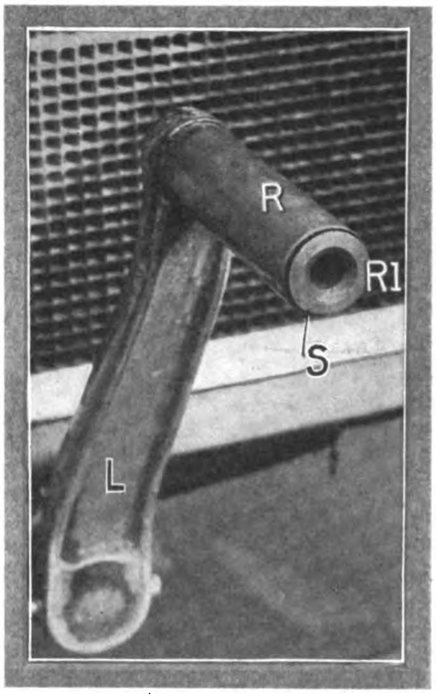

Fig. 1—Starting handle of a car showing how the roller and the rivet are related to each other

In the starting handle, shown in Fig. 1, there is an appreciable slide of the roller R and the gap at S forms a knife edge with the rivet that prevents it from slipping off. Fig. 2 shows a hand gripping the starting crank, and owing to the shortness of the handle only 3 inches thereof comes into contact with the hand. In the first place this makes it difficult to crank the motor, even were the handle made so that the operator's hand would not be injured in the operation, but in addition to this drawback the sharp edge of the rivet and the roller together pinched the flesh, and, as can be seen in the illustration, Fig. 2, the moment the handle is turned there is a certain amount of outward pressure which tends to draw the roller into tight contact with the rivet. Fig. 3 shows the operator's hand after starting the motor two or three times. This could have been avoided, of course, by the simple expedient of wearing gloves, but even then the palms of the gloves would be the sufferer and in a very short space of time they, too, would be worn out and useless. When working on a car the hands become begrimed with dirt, and this is carried into the cuts inflicted by the sharp edges. A healthy body may not be affected by this injection of extraneous matter; nevertheless, should the handle by any means be tainted with infection it will undoubtedly be transmitted through the incisions in the palm of the hand, and there is no telling where it may end. The rivet R1 in Fig. 1 is steel and in a position likely to be attacked by rust, which alone is sufficient to cause blood poisoning if allowed to get under the skin.

Simple matters, such as the one referred to, should be found out by the testing staff of any company, and a report made to the proper quarters so that the defect can be rectified and avoid owners unnecessary annoyance. The time has now arrived when designers who have been spending a good deal of labor upon the general efficiency of the car should turn their attention to detail matters. Buyers are more discriminating and small things that tend for the greater comfort are beginning to appeal to them when they are on the point of buying a new car.

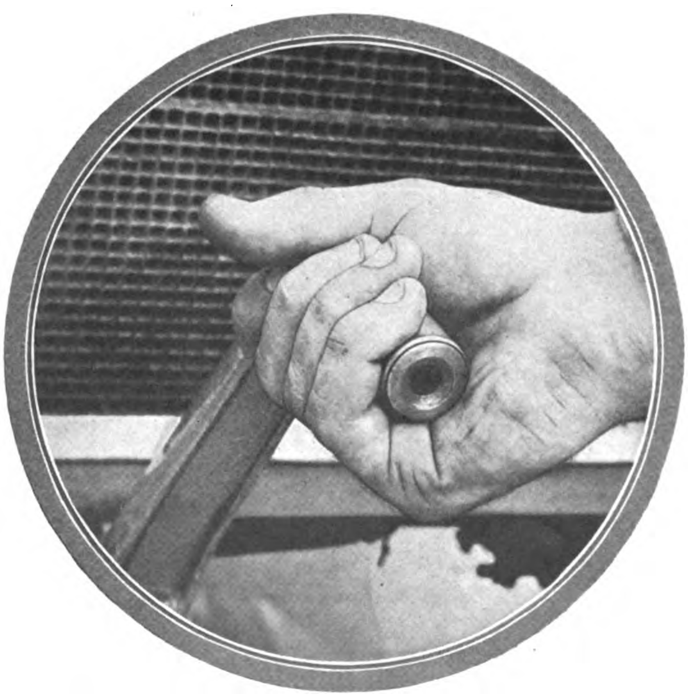

Fig. 2.—Operator in the act of starting the motor, showing how the starting handle is too short and how the roller slides over the rivet

Fig. 3.—The operator's hand after starting the motor a few times being cut by the knife-edge of the starting crank

Rotary Sleeve Valves Claim Attention

Several Types Discussed in Detail

In addition to the reciprocating sleeve valve type of motors considerable attention is being paid on the part of designers to the rotary sleeve valve. The applications are varied and numerous, but it is to be regretted that some designers overlook the effects of the explosion pressure on the valve.

IT has been the object in the present article to present to the public a diversity of types of motor other than the poppet type in order that a comparison can be made of the different lines along which designers are directing their endeavors. The Henriod and Cottereau appeared at the last Paris Salon in the form of commercialized and tried-out products, and it may be mentioned that they attracted considerable attention. It is apparent from the applications for patents that the majority of the older firms are giving the matter careful consideration, and, although no public announcement has appeared, nevertheless the testing departments are endeavoring to produce something that, besides being novel, will have the qualities of being practical and efficient. The more conservative the firm the longer will the public have to wait for the finished product.

W. J. Crossley Operates Two Rotary Sleeves in the Cylinder Head

The sectional view of the Crossley motor (AP) shows the manner in which two rotary sleeves are used to control the incoming and exhaust gases. The piston P1 connected to the crankshaft by the connecting rod C1 operates in the cylinder C2. Within the cylindrical housings, placed above the cylinder head, are two rotating sleeves A and B. Inside these sleeves there are two sleeves C and D and by the slots that are cut in these sleeves the gases pass in or out of the cylinder. The method of operating the sleeves is shown in Fig. AQ. This transverse section of the front end of the motor shows a gearwheel G1 attached to the end of the crankshaft and meshing with another gear G2 which is attached to a vertical shaft S1 rotating in guides G3, G4 and G5. End thrust is taken by the ball bearings B1 and B2. The pinion P2 is in mesh with pinions attached to a pair of the rotary sleeves, causing them to operate in opposite rotation. At the other end of the motor a similar mechanism is provided the inner sleeves D and C. The entire sleeve mechanism runs at one-fourth the crankshaft speed. In order to operate the valves in this motor it is necessary to employ ten gearwheels, which renders it somewhat complicated.

Split Rotating Ring Is Employed on the Cottereau Motor

The Cottereau motor shown in section in Fig. AR conforms to up-to-date practice in every respect with the exception of the valve mechanism. On either side of the motor the exhaust and intake manifolds are situated, and in order to cover and uncover these to permit of inlet and exhaust a cylindrical ring R1 is located in the head of the cylinder, or, in other words, the combustion chamber. The ring proper R1, and shaft S1, together with the boss B1 can be seen in Figs. AR and AT, also the slot S2 through which the gases are allowed to pass as the respective ports are uncovered. It will be noticed that the ring R1 in Fig. AT is split at A and A1, which allows for expansion. The rotary ring is operated by means of gearing G1 attached on the crankshaft to G2, whence the rotary motion is carried by the vertical shaft R2 to a gear G3 which drives the gear G4 through the intermediate pinion G5. The vertical spindle shaft S1 passes through the cylinder head, and to prevent leakage it is beveled at the point of contact with the cylinder head, which is correspondingly beveled.

Screwed on the head of the spindle S1 is a short transverse arm with a vertical stub which is received into a socket on a corresponding arm attached to a worm wheel carried on a vertical shaft. Lubrication is provided by supplying oil under pressure to an overhead oil bath lubricating the bevel and worm gearing and flowing by gravity down the hollow spindle S1 and through the hollow transverse shafts T1 driving the ring to the walls thereof.

Wridgway Uses a Spherical Valve Driven by Bevel Gearing

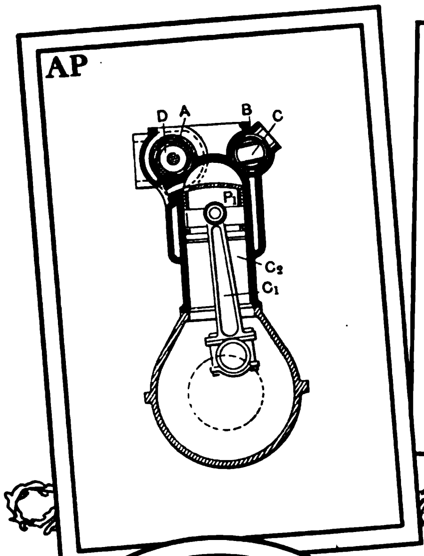
The transverse section of the motor shown in Fig. AS represents the method adopted by C. G. Wridgway and is simple in construction. The sphere C operates in such a manner as to place the intake I and the exhaust E in communication with the cylinder C1 by means of slots S1 and S2. The ports P1 and P2 in the cylinders are thus brought into communication with the intake and exhaust manifolds by the rotation of the ball S, which is operated by the rotating shaft R driven by a bevel gearing off the crankshaft, or by other suitable method. The sphere S is fitted with rings R1 and another which is not shown in the illustration, placed on the cross to prevent the leakage of the gases. The piston P has an extended lip L1 which covers the port at the moment when the explosion takes place, thereby relieving the valve mechanism of undue strain.

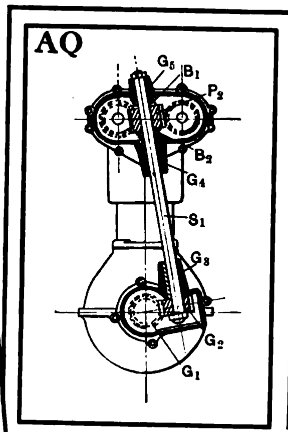
Broc Motor Utilizes a Double Piston Inside the Working Cylinder

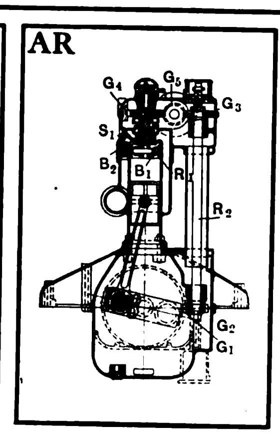
The sectional diagram of the Broc valveless motor shown in Fig. AU is of novel construction. As will be seen in the illustration, there are two pistons, P and P1; the outer one P is revolved by a set of bevel gears B and B1, the latter being attached to the crankpin on the crankshaft and the inner piston driven in the ordinary way. There are two holes in the head of the inner or fixed piston, one for the intake and the other for the exhaust. In the head of the outer revolving piston there is a single hole H1 which as it uncovers the holes in the fixed piston permits the gases to be taken in or exhausted. The gases are led to their ports, by means of a helicoidal groove shown, from the carbureter to the intake port of the piston head and through it into the combustion chamber. To accommodate the angularity of the connecting rod, a slide S1 is formed in the outer piston sleeve for the reception of the fork from the sleeve on the connecting rod, by which it is actuated. The force of the explosion is taken care of by an independent mounting, thereby preventing same from being transmitted to the bevel gearing. This has to take care of the rotary strain alone. The arrows indicate the passage of the exhaust.

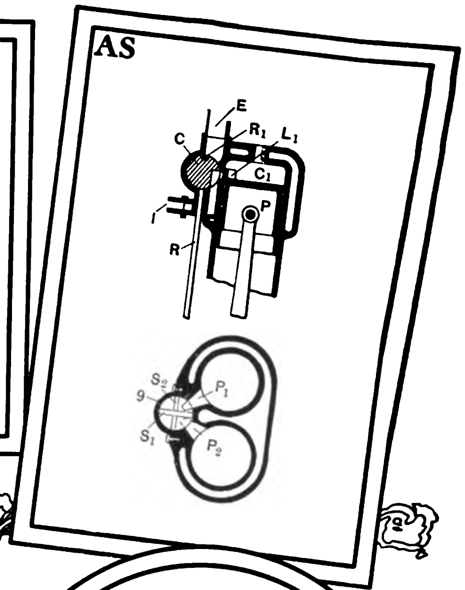
Swift Motor Employs a Horizontal Rotary Sleeve for Each Cylinder to Operate the Inlet and Exhaust

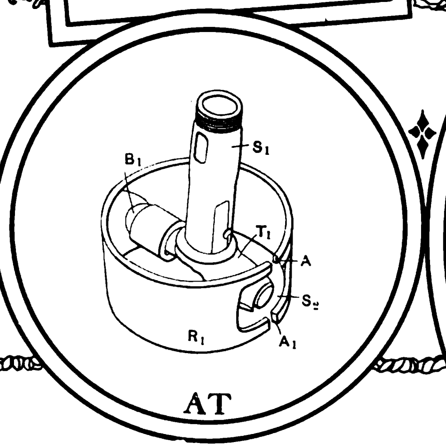
Fig. AV is a cross-section of the rotary sleeve motor constructed by the Swift Motor Company. The sleeve S1 alternately connects the combustion chamber with the inlet port A and the exhaust port E. The sleeve is driven with half the speed of the engine, and is water-jacketed pretty nearly all over

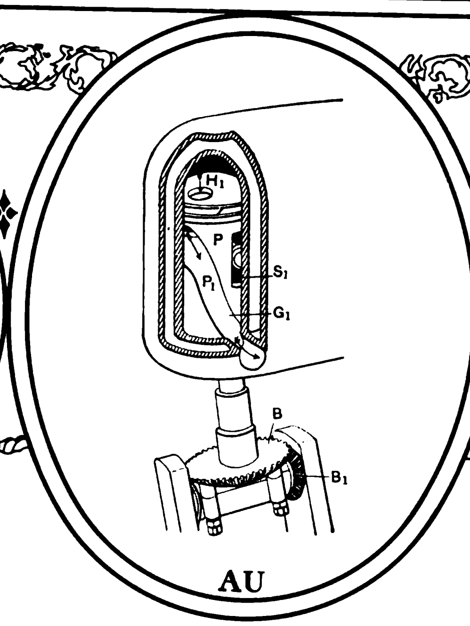


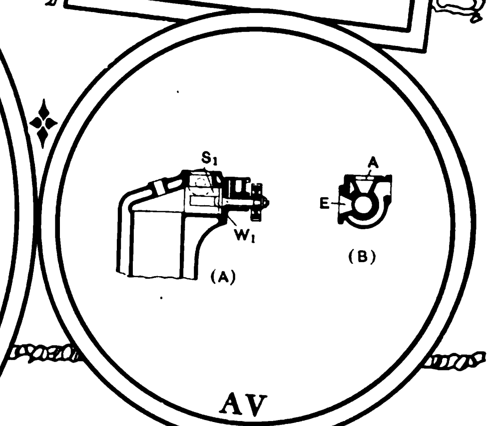












AP—Sectional view of the Crossley motor, showing the valve mechanism and the relation of the valves to the ports

AQ—Showing the method of operating the valves on the Crossley motor with two rotating sleeves in the cylinder head

AR—Transverse sectional view of the Cottereau motor with a split ring valve in the working cylinder

AS—Transverse sectional view of Wridgway motor in which a sphere suitably slotted is employed to control gases. Plan view shows relation of sphere to the cylinder ports

AT—General view of the valve used on the Cottereau motor, showing the port for the entry and exit of the gases and the method of operation

AV—Two sectional views of the Swift motor. A—Cylinder head. B—Valve ports

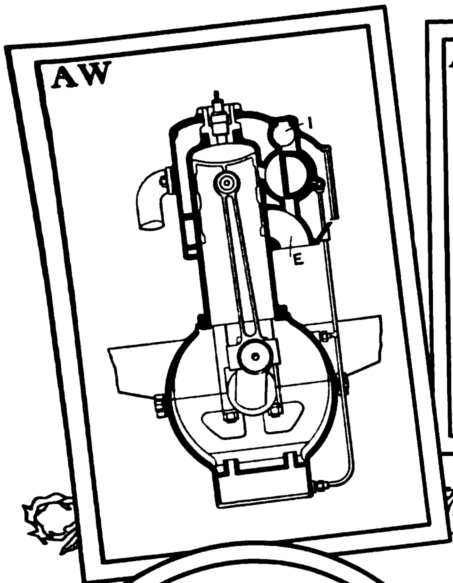
its surface. The tightness of the sleeve is not influenced by the explosive pressure, but this acts upon its back wall W1, pressing the same against the cylinder casting.

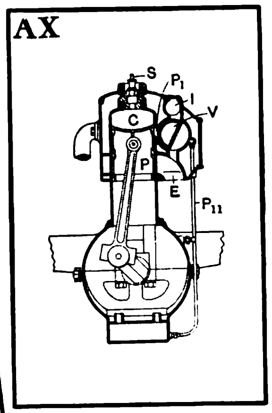
D-Form Corliss-Type Rotating Valve Is Used In the Henriod Motor

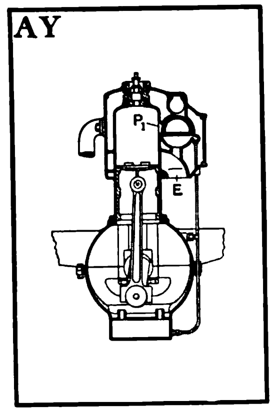
In the four sections of the Henriod motor the relative positions of the rotary valve in relation to the piston are shown. The valve V runs parallel to the cylinder C in which the piston P reciprocates. As will be seen, the water jacketing is well taken care of and the spark plug is placed in the head of the cylinder. Piston P has a concave dish, and, as shown in Fig. AX, the valve V is relieved of the explosion pressure as the piston P covers up the port hole P1, and this takes place during one inch of the stroke, which is four inches in this particular motor. Fig. AW shows the relation of the valve to the piston and the point where the exhaust has closed and the intake is about to open, the exhaust manifold being shown at E and the intake at I. Fig. AX indicates position of the valve on the firing stroke, showing the port P1 covered by the piston. Fig. AY shows the piston at the lower dead center and the exhaust port E about to be placed in communication with the port P1. Fig. AZ shows the port P1 and the port P2 giving free passageway to the exhaust gases that are being expelled by the upward sweep of the piston. The lubrication of the valve V, shown in Fig. AX, is taken care of by the pipe P11, which is in direct communication with the pressure feed system.

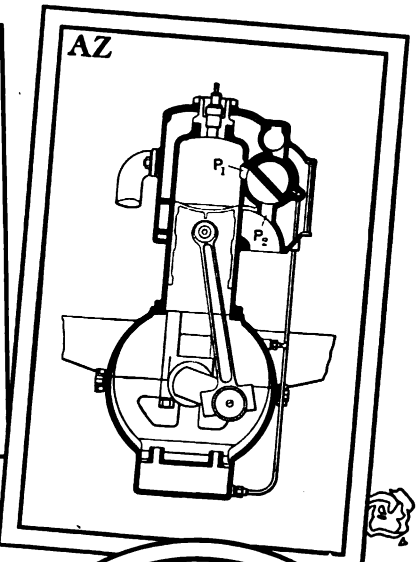
Richards Employs a Reciprocating Piston Inside the Working Cylinder to Operate the Valve Ports

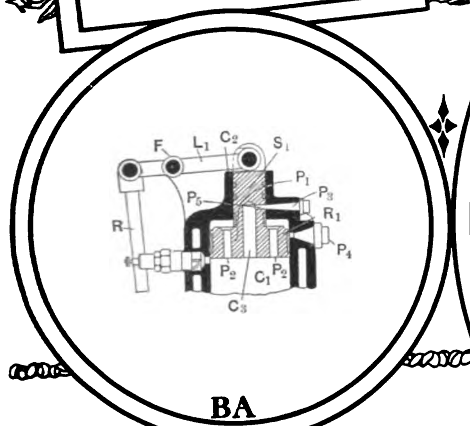
This invention (British patent No. 28,767), registered by J. H. Richards and B. Bellingham, relates to the valve mechanism for controlling the inlet and exhaust gases of a four-stroke cycle type motor. Referring to the sectional view of this motor as shown in Fig. BA, the sliding piston P1 is employed, which is solid or undivided, having passages leading between the upper and lower faces so that it does not exert any binding or braking effect on the cylinder walls. The rod R is operated by means of a cam mechanism, a spring being interposed between the roller and secured to the rod R to maintain the tension of the roller on the cam surface. The sectional view is of the upper end of the engine cylinder C1. The piston valve P1 is fitted with a ring R1 engaging with the walls of the cylinder, and is provided upon its upper side with a central cylindrical stem S1 which passes through and is arranged to slide within the cylinder head C2, the upper end of the said extension S1 projecting above the head and being connected up to the actuating mechanism. Expansion rings are fitted to the trunk extension S1 so as to maintain a gas-tight joint. Passing through piston valve P1 there are a number of passageways P2, while upon the upper face are segments of an annular rib which, when the valve is fully lifted, comes against the under side of the cylinder head. Near the upper end of the cylinder leading to the valve space or chamber is an exhaust port P4, and an admission port P3 is provided in the upper end of the cylinder head, the inner end leading into

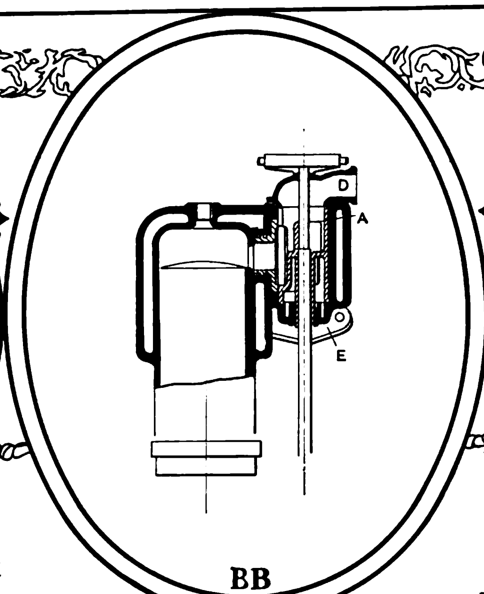


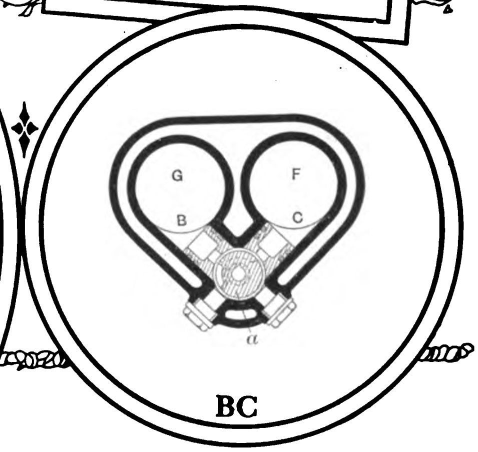












AW—Transverse sectional view of the Henriod rotary valve motor, showing the valve in the midway position with one port about to open

AX—Position of the valve on the Henriod motor during the compression stroke with both ports closed

AY—The piston is near the lowest point of the stroke on the Henriod motor and the valve is about to uncover the exhaust port

AZ—Position of the valve during a part of the exhaust stroke on the Henriod motor. The lubricating pipe for the valve can be seen at the right, leading from the base

BA—Sectional view through a cylinder of the Richards motor, showing how a second piston suitably drilled and slotted controls the gases

BB—Transverse sectional view of the King motor, in which a rotary sleeve valve is employed for each pair of cylinders

BC—Plan section of the King motor, showing the ports in the cylinders together with the rotary valve

the central hole in the latter, within which the valve stem S1 reciprocates. Arranged to co-operate with the inlet port P3 is a port P5 formed in the side of the valve stem which leads into the central chamber C3, passing axially through the stem and piston P1. The lever arm L1 fulcrumed at F to a lug on the cylinder head operates the piston valve. The cam that operates the rod R is so formed as to permit of periods of dwell.

King Motor with Single External Rotary Sleeve for Each Pair of Cylinders

In the King motor, a cross-section of which is shown in Fig. BB, only one rotary sleeve is provided, which serves a pair of cylinders arranged in the manner seen in Fig. BC. The sleeve, which rotates with half the crankshaft speed, is driven by means of a shaft and a set of bevel gears, and the openings B and C in the sleeve owing to their magnitude permit of rapid opening and closing of the cylinder ports, they serving to connect the inlet A and the exhaust passageway E with the respective ports of the cylinder. In Fig. BC is seen the first stage of scavenging for the cylinder F and the beginning of the suction stroke for cylinder G. An oil lead is provided alongside the sleeve.

THE trend of events points to the future better understanding of the radiator problem and to the fact that carbon is formed in the combustion chamber of the motor if the radiator fails to do its part.

Live Axle Makeshift Repair

IT is often found that the V-shaped stay under a live axle will break, and after being repaired in a short time will break again. A careful examination of the axle will disclose the fact that it is out of line and has worn the differential housing so that the axle tubes are loose in this casing.

If the axles and casing are both too thin to be turned down far enough to admit a bushing, the axle tubes may be wedged into the casing by means of strips of thin sheet steel so as to be very tight. The axle is then stiffened by means of a plank which should be 1 1-2 inches in thickness. A suitable wood for the purpose is ash. The top edge of the plank is placed along the bottom of the axle and cut to fit from end to end, the shape of the gearcase being cut from the plank to allow the plank to bear tightly against the casting. The plank is supported and held against the axle by means of four inverted U-shaped straps which hang over the axle. Slots are cut through the plank in the proper positions so as to admit cross pieces which pass through the plank. These cross plates, which are about 3-8 in. in thickness and about 1 1-2 in. in width, are drilled to take the 3-8 in. diameter straps. Bolts and lock nuts are placed on the ends of the straps and drawn tightly home. To strengthen the lower edge of the plank two flat bars of iron, 1 1-4 in width and 1-4 in. thick, may be bent to the shape of the bottom of the plank, which is sawn so as to taper toward the ends. The iron is bolted on with 1-4-in. bolts.

Shortcomings of the Average Body

Stock Bodies Are Often Uncomfortable Contraptions

As cars are sold at the present day the buyer has little opportunity to make provision for his personal comfort, and many an otherwise pleasant tour is turned into a nerve-racking trip by want of forethought in body building and equipment.

WITH the practice of selling cars fully equipped, buyers are compelled to take things just as they find them, and if they have any particular ideas of their own as to the requirements to suit their particular needs, in the majority of cases the body has to be rebuilt in order to accommodate them. There is no reason why a body should not be so built that the running boards could be denuded of tool chests, tire-carriers, and the like. The system in vogue on the Continent of selling the chassis and leaving the coach work in a measure to the buyer to decide has material advantages from the point of view of comfort afterwards; but, nevertheless, it is a good deal more costly to have a special body built than to take one of the stock models that are built by the hundred.

The advent of the fore-door has done much to render the front compartment more comfortable and the body more sightly. In the aim for comfort, some body designers overlook a pleasing aspect, whereas it should be their aim to make a combination of these two most desirable features. In Fig. 1 can be seen the method employed on the Chalmers roadster permitting the driver to enter the car on the right-hand side through a door which is made to open. This is effected by placing the levers sufficiently far forward so that they do not block the passageway. Although coach-builders may be blamed for some of the lack of comfort in the bodies that they turn out, nevertheless, if they have to build a body upon a chassis that is not suited for the purpose, the blame does not rest entirely at their door. It would be a good plan if manufacturers of cars were to take the gear-shift and brake levers into consideration, and make provision whereby the steering pillar could be raised or lowered by an adjusting device. With a fixed steering pillar, or one that necessitates the dismantling of the motor, fitting new brackets, or re-drilling the old ones, cannot be expected to suit everybody that sits behind it. The same applies to the pedals, and it is curious to see how some people will go through contortions and even body discomforts, whereas by lengthening or shortening the pedals, as the case may be, they could be made to suit the requirements of the driver.

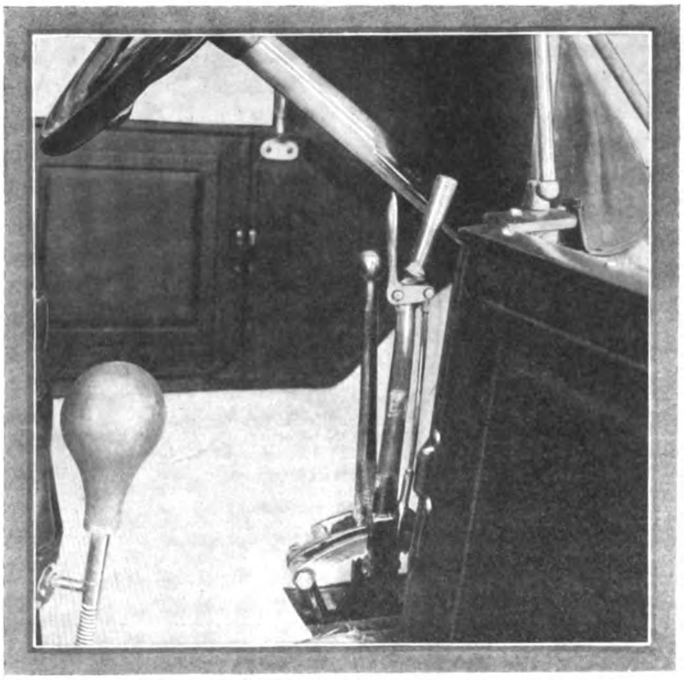


Fig. 1—Showing how side doors are made to open on the Chalmers, with levers placed so that driver can get in without disturbing passenger

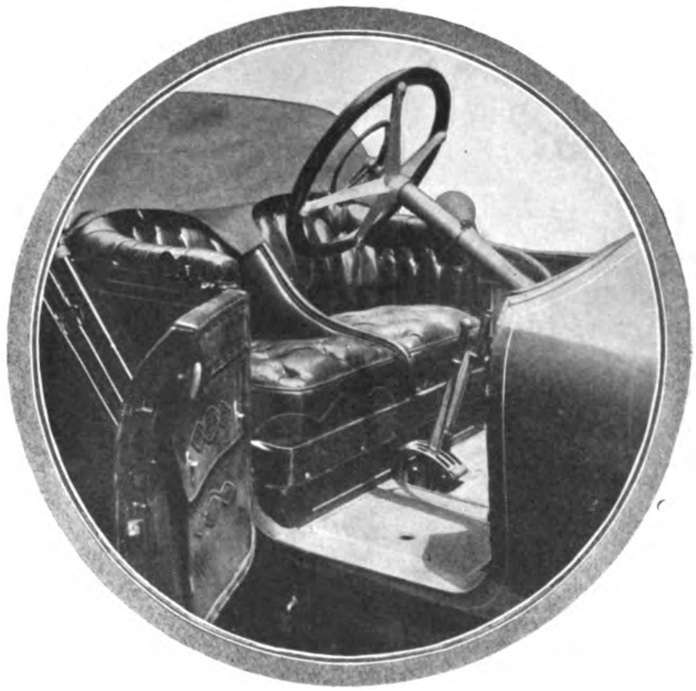

Fig. 3—Entrance to driver's seat made easy on the Overland by placing the gear and brake levers in the center

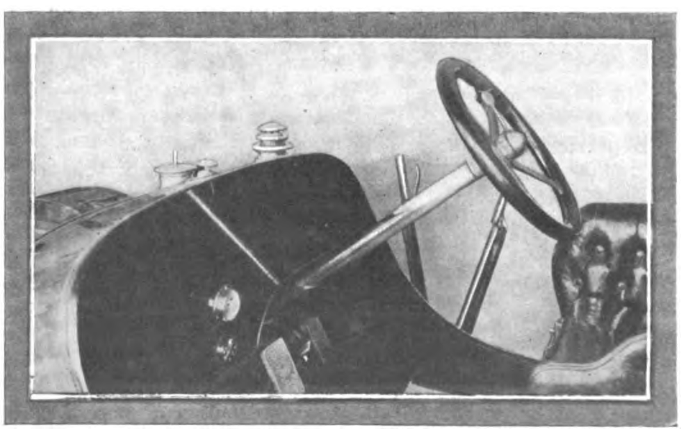

Fig. 2—Cowl of the dashboard used as a gasoline tank, with a recess cut away for the pedals, but the levers are placed very far forward

The method adopted in Fig. 2 of raking the wheel considerably, and fitting the front seats low down, tends to add comfort to a long day's drive, but in this instance when the coach-builder has endeavored to do his part of the work satisfactorily he is thwarted by the chassis-maker in so far as the levers are placed almost out of his reach. This illustration tends to show that there must be co-operation between body designer and chassis-builder. Of course the levers could be linked and bent back near the reach of the driver's hand, but after all is said and done this is only a makeshift and gives the car an unsightly appearance. What is required in this case is that the bracket carrying the levers should be given a rearward incline, and the keys that hold the levers to their shafts be reset. While studying this illustration one good point will be noticed; the dash has been left particularly free. The cowl, which is made fairly wide, has been turned into a receptacle for a capacious gasoline tank, and the side facing the occupants has been neatly finished off with a mahogany covering to which the switch and pressure gauge have been attached. The right side of the dash, as will be seen in the illustration, has been cut away, leaving plenty of leg room for the driver to operate the pedals, and instead of leaving the rubber mat below the driver's feet unprotected to the constant wear a piece of patent leather has been sewn onto this portion.

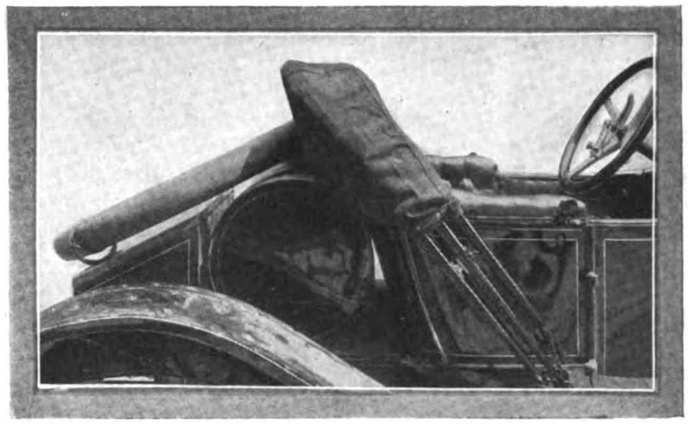

Fig. 5—Arrangement on the rear of the Overland runabout for carrying the gasoline tank, tool box and spare tire. The lowered top also improves the appearance

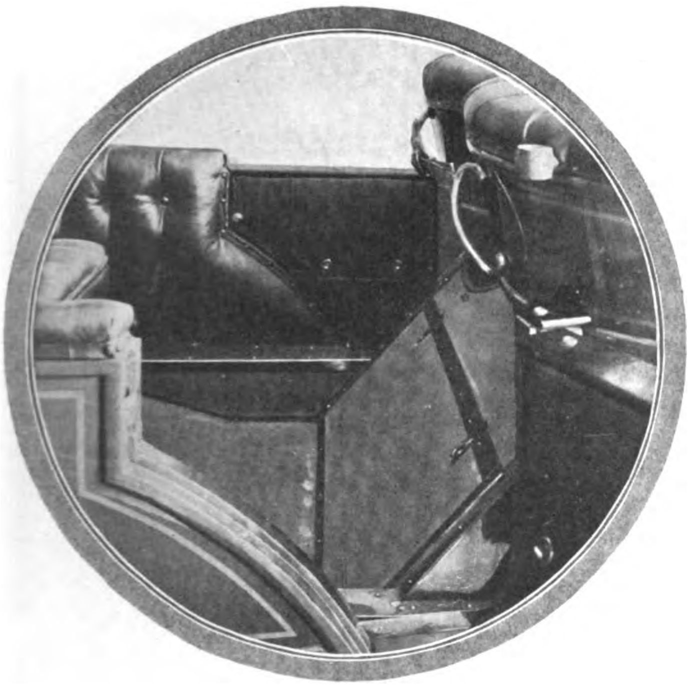

Fig. 4—Tool box and foot rest on the Speedwell car which does away with boxes on the running board and gives comfort to the passengers

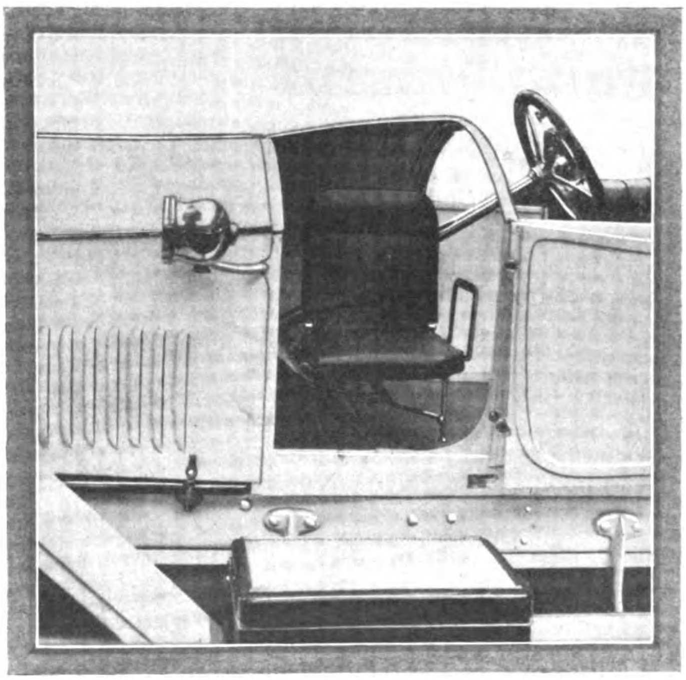

Fig. 6—Method of utilizing the waste space under the large cowl for the extra seat, which can be folded away if not required and the cowl closed

A change that is taking place in chassis design, and one which gives the body builder more scope, is shown in Fig. 3. Here it will be seen that instead of placing the levers so as to be operated on the driver's right hand they are placed centrally, leaving the passageway when the door is open free for the driver to get in and out without disturbing the other passengers.

In the days when horse-drawn carriages were in vogue it was usual to have a driver and footman on the box, but now that the footman has been dispensed with in the case of the automobile and the available seats are occupied by the owner and his friends, such provision as this is a great help for the driver to get out quickly in order to open the door of the rear compartment. Runabout bodies, for the most part, offer great possibilities to the coach-builder, but the manner in which tops are fitted to this type often renders the appearance far from pleasing. The suction created by an automobile in passing through the air usually causes a back-draft with the consequence that unless the back of the car is sufficiently high dust and mud will be thrown on the backs of the passengers. By fitting a second bracket for the top, as shown in Fig. 3, the irons can be dropped, and besides being more sightly the back-draft is obviated. Reference was previously made to the question of eliminating tool-boxes from the side platform steps, and the method adopted by the Speedwell Company, as shown in Fig. 4, is worthy of notice. Considerable attention has been paid heretofore to the driver's seat and to the happy possessors of the front compartment of the car, but, beyond some refinements along the line of fittings and upholstery, the passengers in the rear of the car have been left severely alone. Anyone who has sat on the rear seats of a car has experienced the uncomfortable slipping sensation, not to say insecurity, while driving over bad roads, and this is due in a large measure to the poor foothold afforded. Immediately behind the front seats in this illustration will be noticed an inclined box capable of containing a goodly number of tools and spares, but which, when closed as shown, affords a resting place for the passengers' feet; the purchase thereby obtained adds considerably to the comfort of the occupants. One disadvantage that this brings with it will be noticed by the slightly restricted passageway, but this should be set against the comfort while driving, and, if anything, the advantage is for the latter.

The chauffeur is a necessary evil to some autoists who either do not wish to attend to their own cars or who drive for the

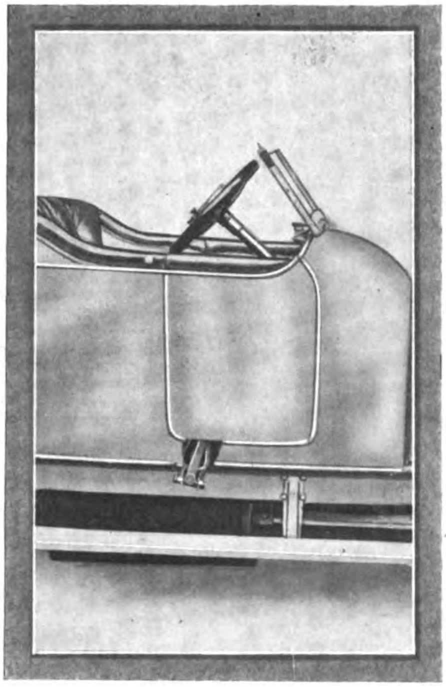

Fig. 7—Another example of utilizing the dash cowl for a gasoline tank, with the filler behind the slanting windshield

sake of driving and have not taken the trouble to master the intricacies of the mechanical parts. Then, again, there is the question of tire trouble and the owner would sooner carry a man to attend to them than do so himself. The question then arises where to put him, and the solution is either that he sit alongside of the driver or on a small dickey on the footboard. In the majority of present-day roadsters the rear of the driver's seat is occupied by a gasoline tank, luggage, and tires, which prevents the dickey being placed in this position. If the two seats are occupied by the driver and a passenger, the dickey has to be resorted to, unless some such provision is made as shown in Fig. 6. The cowl is made in two sections, one half being caused to slide under the other, and the extra seat, which can be folded and stowed away when not in use, is brought into service and the chauffeur provided with a seat in the manner shown. When the extra seat is not in use the appearance of the car is not marred by a permanent fitting, as the cowl is entirely closed in the manner previously indicated and a door is provided to complete the fore-door effect. A separate door, of course, is used to obtain entrance to the driver's seat.

The appearance of the rear of the car as shown in Fig. 5 is not at all displeasing, and the gasoline tank, tool box and spare tire are taken care of in a simple manner. This illustration also shows how this has been made possible by dropping the front ends of the top stays. Previous mention has been made to the feature of carrying the gasoline tank under the cowl of the dash, and Fig. 7 offers another example of this. The filler cap, instead of being placed in the dash proper, has been carried behind the windshield, which latter can be pushed forward while the tank is being filled. This type of front compartment is very comfortable, as the seats are placed as low as possible and the driver's head does not come above the level of the back rest. The levers in this instance are placed very low down and it has been found necessary to break the lines of the body in order to accommodate them. A little forethought on the chassis-builder's part might have obviated this.

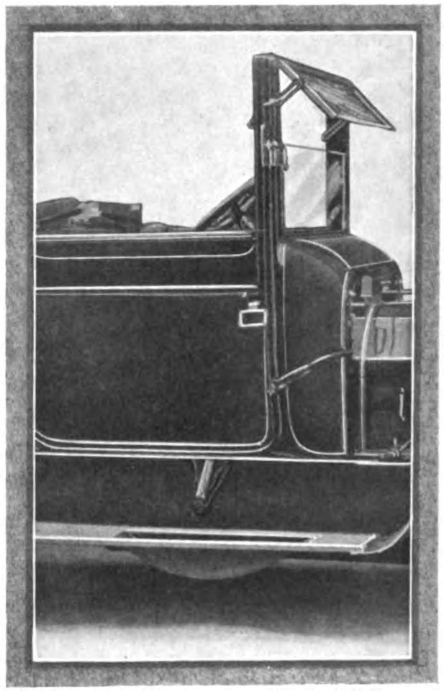

Fig. 8—Dashboard in a closed car, fitted with a glass window to permit the driver to properly see the dash fittings

Now that closed cars are being used more largely, it is necessary to adopt some provision other than electric light to permit the driver to see the gauges that are placed upon the dash-board. In Fig. 8 the top part of the dash has been fitted with a glass window, allowing the light to enter and shine upon the fittings. Provision has been made in this body to permit the driver to tilt half of the glass screen forward in order to obtain a better vision on a rainy day, or to allow a passage of air into the compartment when the body is used as a closed car. Fig. 9 shows how the dashboard cowl can be extended and a windshield placed thereon just above the steering wheel, the type as shown in Fig. 8 being hinged at the top so as to swing outward from the bottom. The extension of the top is carried over the dash and under these circumstances it would be almost impossible for rain to enter. Figs. 10 and 11 show the cowl extended, the sloping bottom half being made either of leather or glass insert and capable of being laid down as shown in Fig. 10 or raised as shown in Fig. 11. It will be noticed in Fig. 11 that there are locking hinges at the top, and using these as hinges the screen can be tilted forward.

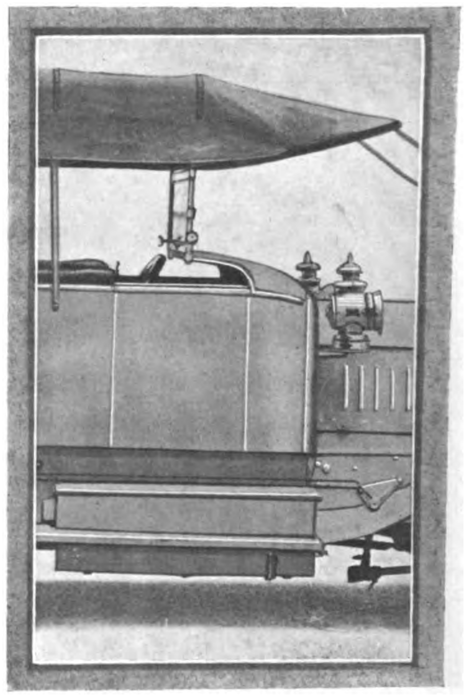

Fig. 9—Cowl extended so as to bring the windshield closer to the driver and the top given an extra extension for better protection

An extended cowl, such as is shown in Fig 12, offers some difficulty in the fitting of windshields, but this has been overcome in the manner shown. Locking devices are fitted to the base of this shield so that it can be used as a wind deflector when placed in the manner as seen in the photograph, or in a vertical position, so that the turn buttons that are screwed thereon can be attached to the extension of the top, thereby excluding all rain.

Gasoline-Electric Passenger Service

After years of experiment and disappointment with different methods of propelling the small passenger vehicle to take the place of the dirty and unsatisfactory small locomotives and cars, the "automotrice" has made a hit abroad, and seems to have come to stay. This is a car operated by electricity which is generated by a gasoline motor.

THE greatly varying conditions in Europe which confront the builder of a passenger vehicle seem, after a long struggle, to have been at last solved to a certain degree by the installation of the gasoline-electric car, generally termed "automotrice." The most notable installations have been made in Hungary, Germany, Holland and France. England and Sweden, after having carefully watched the success of these cars in the countries in which they have already been in operation, have also placed orders for several of them.

The first experiments in the direction of self-propelled cars were made with steam motors. These proved to be very hot and uncomfortable in the summertime; the smoke and dirt present also being very annoying. The next step was in the direction of a gasoline motor-driven car. This was brought about by the great progress in the automobile, and it was expected that the gasoline motor could be adapted to the requirements of short-distance passenger traffic. The latest experiments turned toward the gasoline-electric cars, which, from the results recently achieved, give the idea that the problem has been, to a large degree, solved.

The success of the gasoline-electrics can be attributed to the following: Simplicity, due to the fact that the apparatus has been

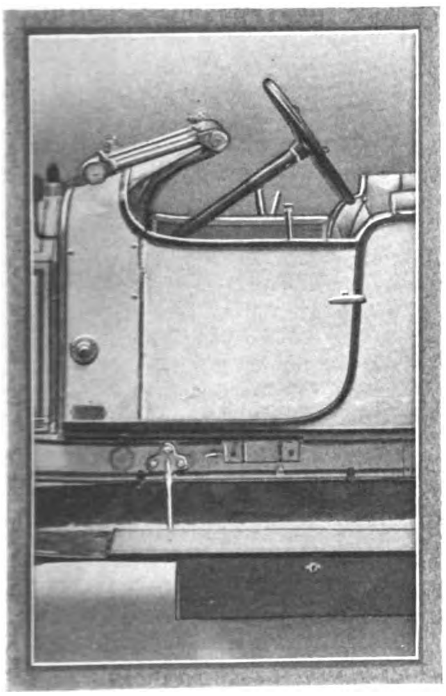

Fig. 10—Extended upswept dash with the windshield folded forward, giving the driver clear and uninterrupted vision

cut down to an elementary form, consisting of a gasoline engine, directly connected generator and secondary motors on the axles of the cars, giving a direct drive to the wheels. Reduction of weight is also a factor in the success of these cars. The modern automotrice, with a seating capacity of 40 passengers, will not weigh more than 20 tons, while an American electric car would weigh about double that amount. The power equipment of the European vehicle would be either a 60 or 90-horsepower generator group which, in a car of this weight, will give it a speed of from 25 to 40 miles per hour on level ground.

The commercial returns of the investment have ben excellent, one line showing $100,000 annual profit.

When Judgment Whispers Don't

DON'T judge a car by its reputation alone; its character should also be taken into consideration.

DON'T forget that the best set of brakes in the world are of little use unless applied at the proper time and with judgment.

DON'T fail to remember that a well-cared-for automobile is a potent illustration of the virtues of reciprocity.

DON'T forget that the monotonous regularity of a well-performing motor may be broken by the judicious application of a poor quality of lubricating oil.

DON'T overfeed the motor—dyspepsia and loud retching noises are bound to follow over-indulgence.

DON'T neglect the hour of preparation that may insure the week of touring delight.

DON'T waste sentiment upon a motor—lubricating oil may be what it needs most.

DON'T discriminate against the motor in your automobile unless you desire to be paid in kind.

DON'T forget that the product of a well-matched team is always good.

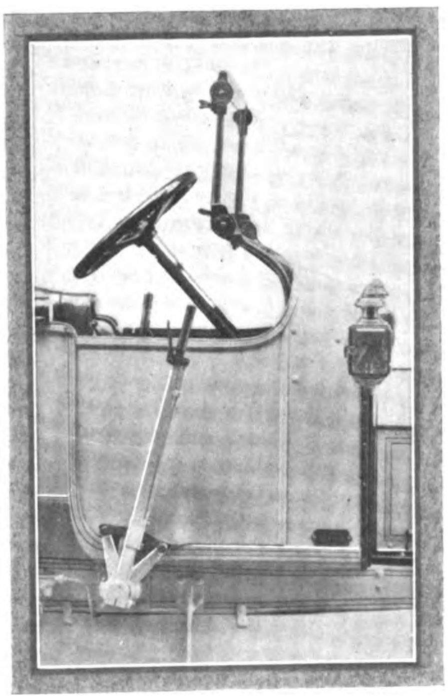

Fig. 11—Dash similar to the preceding with a windshield that offers the driver the option of opening it from the top by swinging the bottom forward

DON'T violate basic principles in building up a plan.

DON'T attempt to demonstrate the straight-line axiom when there is a telegraph pole or a wire fence in the way.

DON'T despise a horse when you can't get your car out of the mire in any other way.

DON'T forget that perfunctory preparations for a tour will surely spoil your pleasure.

DON'T look down upon the pedestrian; he may have tired of automobiling, and is waiting for his new aeroplane to be delivered.

DON'T, if you are a freight automobile salesman, dilate too enthusiastically upon the superiority of your wares over the customer's horse-drawn equipment.

DON'T allow him to hope for results unless he consents to the establishment of a well-equipped service.

DON'T forget that a failure to show results is worse than not to have made the original sale, for you have lost your future market in so far as that client is concerned.

DON'T drive the second nail until the first is clinched.

DON'T take for Gospel all that the glib salesman tells you; the salesman must "know" even if he has to fabricate.

CANADA'S CARRIAGE MAKERS TURN TO THE AUTOMOBILE—To gain a graphic idea of the growth of the automobile industry as it obtains in Canada, one needs but to take a walk among the shops formerly devoted to carriage body building. Judging by the attitude of the men who conduct these industries, it is evident that the manufacture of horse-drawn vehicles no longer affords the mechanic the same opportunity to earn his bread that it did a decade ago.

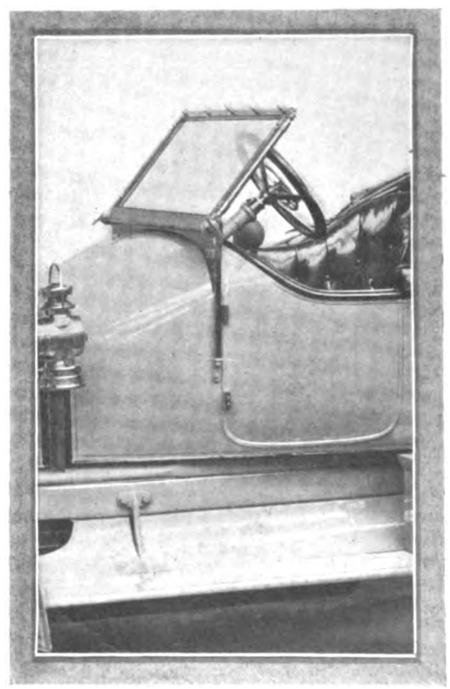

Fig. 12—Method of fitting a top to a curved cowl. The shield is fitted with a locking device whereby the position can be altered at will

Cooling and Efficiency

Suggested Improvement of Present-Day Engines

Without being specific and giving composite data to those who are looking for increased efficiency, the following article, which appeared recently in "La Technique Automobile et Aerienne," points out some of the advantages and disadvantages of present-day motors, and to improve efficiency the suggestion is given that higher compressions will furnish a solution of the problem. In dealing with the advisability of dispensing with the cooling system the author believes in sticking to the evils that we have rather than fly to others that we wot not of.

DESPITE the great amount of work that has already been accomplished, unity among the diverse types of thermic motors is far from being realized. The steam engine, contrary to the predictions that were made on the appearance of the gas motor, continues to merrily carry the handicap of 606 calories lost in vaporization.

This is reduced from time to time by increasing the compression, as well as by superheating, water-jacketing, and above all by the condenser. Its suppleness, security in operation, and easy-starting qualities, together with its reversibility, render it without doubt—at least for some time to come—a necessity for locomotives.

On the sea in the case of large ships the turbine is its only rival. But this type of motor, if it competes with the older type of piston motor, strengthens the position of steam in comparison with industrial motors of the internal combustion type. These latter, with the exception, perhaps, of specially constructed powerful motors utilizing the residual gases of the blast furnace or the coke furnace, are generally employed in installations of medium power. And even for such the steam engine is holding its own, and the recent application of the central exhaust on single-cylinder condensing engines is not favorable to the extension of explosive motors.

In several instances, however, they have a manifest superiority which is incontestable. But for aviation internal combustion motors were not indispensable, for the contrary was shown by the experiments of Ader. But they are expanding rapidly into other fields, such as submarine work, and for fishing boats, and the suggestion has even been made to equip fairly large vessels with them.

But if the two great types of thermic machines have in their own special fields a justifiable vogue, nevertheless there is a competition raging in many others. The motor that will win out in the long run will be the one that has the greatest efficiency, using this term in the broadest sense of the word, and not including in it only the question of consumption of new parts and repairs, but also the expense of running or of difficulty in keeping same in order. The author states that he is one who believes that the future holds great things in store for the explosion type motor, and endeavors to show a small side of the problem that is paramount in the minds of the industry—the search for high efficiency.

It would seem, in looking at the imperfections of the motor of the explosion type, that the greatest of these lies in the cooling problem. It is found that water absorbs some 40 per cent. of the calories that are contained in the combustible. From this alone it is seen that it is impossible to work a piston in a cylinder above a certain temperature without suffering loss of efficiency. This is subject to modification. But supposing that without modifying its general properties one were to construct a motor in which the two following conditions were obtainable, it would be said that such a motor was only theoretical:

(1) that the piston remain airtight and in good working order no matter what temperature it was called upon to work under;

(2) and at these temperatures self-ignition of the mixture was not a thing to fear—

All other properties of this motor being the same as those of an ordinary motor as at present constructed.

It ought to be pointed out in the first place that adiabatism due to the walls is hardly possible of attainment even if the exterior of the cylinder is fitted with a thick layer of heat-retaining material. It does not suffice to attain the adiabatic condition by preventing the heat from passing through the thickness of the cylinder. Another difficulty to be overcome is the prevention of the walls storing heat until a certain moment, to give it back in the next moment—a problem which is more difficult of accomplishment than the first.

Let us compare the phenomena that take place in the motor as above described with those produced in an ordinary type of motor having the same characteristics, but which is cooled. Presuming that an equal amount of combustible mixture is taken in each cycle by both motors, the pressure diagram will be slightly higher in the uncooled motor than in the other on account of the difference in the temperatures. But this advantage, although small, is perhaps completely destroyed by the detrimental action of the walls. These absorb some heat during the expansion stroke or at least at the commencement of it. They give this heat off to the burnt gases during the exhaust stroke; they heat the mixture during the suction and compression strokes—all harmful phenomena which without doubt will compensate for the small amount of gain that will be shown later. This heat that is carried off in the cooling is only utilized in a very small degree by the second type of motor. In addition the heat is carried off by the gases through the exhaust, which leave at a much higher temperature. Therefore the cooling is not a bad application in itself, because if a means were found to dispense with it, all other things being equal, the calories of the combustible could not be utilized to better advantage. It is not a question, therefore, of the losses caused by the imperfections of the mechanical working of the piston, but rather a loss of a cycle, and it is along these lines that improvement should be directed.

For that end one and only one method is available, and that is by augmenting the compression. The more the compression is augmented the lower will be the mean temperature of the gases, consequently less unused calories will be carried off by the water. Diesel takes advantage of this phenomenon and proposes a motor with high compression without cooling. The kerosene motors that he has turned out so far are an experimental proof. These lose to the cooling water per horsepower hour about one-third of what is lost in the same manner by ordinary explosion motors with much lower compressions. Whereas these types rarely ever attain a 25 per cent. efficiency, the Diesel often betters 35 per cent. for large power plants. On the other hand, if the simple augmentation of the compression permits this important loss to be minimized, as we have just seen, it is useless to pass from the cooling to some other manner, because there would not be any economic advantage. It would seem to be a relatively easy matter to imagine some mechanical disposition that would permit a piston to work in a cylinder under high temperatures, and it is proposed to return to this later. But, as we have just seen, the solution of such a problem is void of interest.

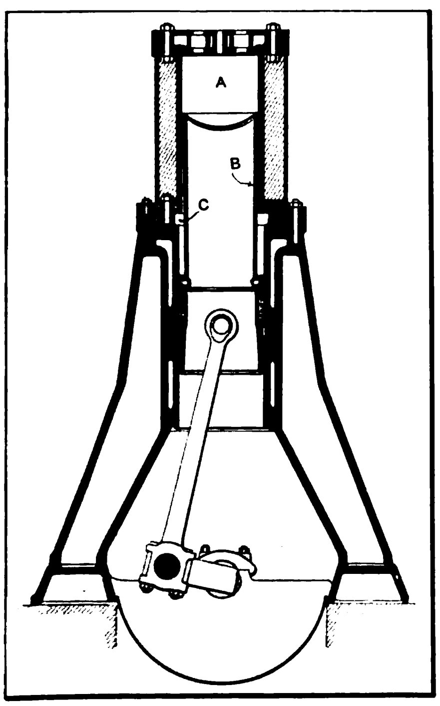
No matter from what side the question is viewed, it will be necessary for those who wish to build internal combustion motors of great efficiency to follow the ordinary practice in the employment of high compressions. It will be impossible to use the "explosion" motor above certain limits, the degrees of which will depend on the weakness of the mixture, on account of self-ignition. Then the Diesel type of four-cycle motor for liquid or pulverized combustibles will be used, or the Gardie type of two-cycle for gaseous combustibles or even for the others.

The Gardie motor is to the gas variety what the Diesel is to the kerosene. It is to be regretted that the trials of this type of motor were not carried out further, as no doubt it would have given excellent results. Unfortunately the few tests that were made were only with compressions that seem very low at the present day. Such a motor is perforce fairly complicated, and is not interesting for that reason.

The growth of compression must have a limit, and in order to understand this one has only to think for a moment of the inconveniences that would be engendered by an exaggeration. All the working parts would have great strains to support and would have to be reinforced. A piston submitted to excessive pressures rapidly renders the cylinder walls oval; it would be difficult to overcome this by lengthening the connecting rod because it would soon become formidable.

If the price of a machine for a given power varies in an inverse ratio with the efficiency; a limit would soon be attained above which there would be little use in going. On the other hand, the interest presented by the increase of efficiency lessens as this increases. An augmentation from 10 to 15 per cent. will furnish an economy on the combustible primarily employed of one-third, whereas if the machine already has a 25 per cent. efficiency and by bringing this up to 30 per cent. one would economize more than one-sixth of the primary combustible. It will be noticed that this is less than in the first case cited, on account of better efficiency, and it shows that the absolute economy realized in passing from 25 to 30 per cent. is not more than one-fifth of what can be obtained in passing from 10 to 15 per cent.

This is why one would stop short in the research for high efficiency much below the figures of the Carnot cycle. And when all motors have attained a sufficiently high efficiency for the purpose for which they are intended, the industrial choice will no longer be guided by matters which seem almost of secondary importance in certain cases, such as simplicity, regularity in running, cost price, durability, and so on, although such considerations have a good deal more importance than some people attach to them. Now to deal with the subject previously referred to, viz., the working of a piston in a cylinder of an uncooled internal combustion motor. According to the author, there should be no difficulty in obtaining such a condition. It would not be possible to retain the type of piston that slides easily in the cylinder. One could employ a piston similar to that shown in the accompanying illustration, with a diameter slightly less than the cylinder, without any point of contact between the two members.



Sectional view of a motor referred to in which a double piston and cylinder are employed in order to obtain a piston that will operate in a cylinder at high temperatures.

By this means we would have a second piston and a second cylinder forming part of the main cylinder and joined thereto. It works at low temperatures because between the hot part of the motor A and the lubricated piston there is an annular body of gas B which will prevent the heat from being transmitted. It remains to provide that these gases shall not be in constant motion, and this can be arranged by calculating the different diameters and the volume in the space C so that the pressures at A and C shall remain practically constant. Cold air could be injected at C which would prevent the piston as well as the airtight cylinder from heating.

This principle has been employed by different inventors, among whom may be mentioned Gardée. It may be noticed that a large number of inventors set themselves to the task of solving oftentimes arduous problems without perceiving that there will be little utility gained thereby. The preceding example is among this class; nevertheless it might be worthy of consideration in the case of pulverized combustibles. But that time has not yet arrived.

Changes in Thermal Efficiency

The products of the exhaust form the greatest clue to the thermal efficiency of the motor. These products change under different load conditions and for this reason the thermal efficiencies vary with the load.

FOR a given motor there will be a certain load at which the combustion in the cylinder will be most complete and the exhaust will contain the minimum amount of combustible material. The greatest heat value will be obtained from the fuel when the greatest amount of carbon monoxide has been burned to carbon dioxide and the greatest amount of hydrogen has been consumed. Hence the presence of an excess amount of carbon monoxide and free hydrogen in the exhaust shows that the motor is working at a low thermal efficiency.

Taking an average case it will be seen that under full load the amount of carbon monoxide present will be 3.31 per cent. of the total volume of all the exhaust gases and the hydrogen 1.19 per cent., while with part load the carbon monoxide was 6.9 per cent. and the hydrogen 2.4 per cent. The free oxygen in both cases was very nearly the same, figuring on a percentage basis showing that under all conditions an excess of oxygen above the theoretical amount necessary to combine with the fuel is required. It is impossible under the conditions we are at present working to secure what might be called a perfect exhaust, that is, an exhaust in which there will be no trace of uncombined fuel, but there is a field here for the designer to raise the thermal efficiency of the modern engine by a partial removal of this source of loss. The other heat losses seem to be a necessity since we cannot dispense with a cooling agent of some sort, nor can we have a bearing in which there is not some loss due to the heat of friction. There is a load condition, however, under which the loss due to unburned gases in the exhaust will be a minimum and the thermal efficiency a maximum. The conclusion to be drawn from the fact that working under a reduced load is working with reduced efficiency points out the bad economy of overpowered plants.

SOME of the German tire manufacturers give a guarantee on tires "for 10,000 kilometers, to be run within twelve months from the date of delivery," under conditions which restrict the heft of loads.

What Some Subscribers Want to Know

Removing and Replacing Piston Rings

Editor THE AUTOMOBILE:

[2,761]—I intend to take the piston rings from my motor and clean them. Before starting to work, however, I would like to have full and detailed information as to how to go about removing the rings and returning them to their proper positions in the piston. If you could supply me with the desired information I should be very much obliged. I wish to start upon the work at once and would appreciate an early reply through your columns or by mail. A. W. SCHEDE.

Islip, N. Y.

There are several good methods in vogue to remove the piston rings without doing them any damage. One of the best and most practical ways is to take a piece of stiff copper wire flattened at one end and insert it beneath the ring at the cut. The ring is then pried up by means of the wire until it is lifted clear of the groove. A piece of brass about one-half inch in width and two inches in length is slipped beneath the ring, thus forming a bridge across the groove. The accompanying cut, Fig. 1, shows the first strip of brass inserted. Other strips are inserted in the same manner all around the ring, which can then be slipped off the end of the piston.

The rings are replaced in the same manner, the order of procedure, of course, being directly opposite to that of the removal of the rings, care being taken to put the rings back into their proper positions and not to bend them too far, as they are brittle and easily broken.

Trying to Blow Up the Muffler

Editor THE AUTOMOBILE:

[2,762]—As I am a constant reader of your paper I am taking the liberty to

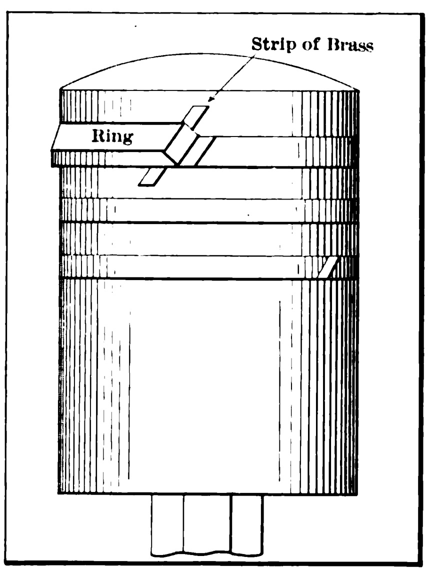


Fig. 1—Showing strip of brass inserted under piston ring in order to slip the ring off the piston

ask your advice on the best way to go about curing the trouble to which my motor is greatly addicted. Every once in a while a series of explosions will take place in the exhaust pipe and muffler as if the engine were doing its best to put the muffler out of commission. I should like to know what the causes of these muffler explosions are and if they are dangerous? K. M. KARCHER.

Portsmouth, N. H.

Explosions in the muffler are in every case due to the presence of unburned gases which have passed through the exhaust pipe owing to misfires in one or more cylinders. The unburned gases pass through the exhaust line into the muffler and are ignited by incandescent particles of carbon or metal or by the heat of the exhaust of the next explosion in the cylinder. These explosions are not as a rule dangerous as far as bursting the piping is concerned, but in an enclosed garage

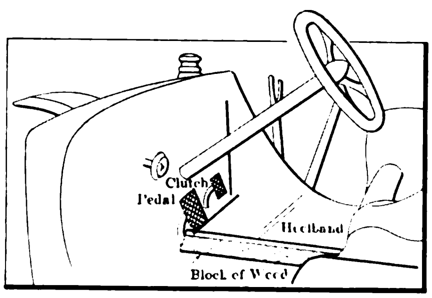

Fig. 2—Method of blocking back pedal while repairing the clutch

where there is gasoline vapor in the air, they may be the cause of starting a serious fire.

A Trip to the Repairman Necessary

Editor THE AUTOMOBILE:

[2,763]—I am very much bothered by the cooling water boiling in the radiator and by back firing while running slowly. Would you kindly tell me if these have any bearing on each other and how they may be prevented. OLD SUBSCRIBER.

Bath, Me.

There is no doubt something wrong in the water circulating system which is responsible for all the trouble. Through not being sufficiently cooled the combustion chamber becomes over-heated and causes pre-ignition, and the backfiring is directly traceable to this.

In Trouble with a Biting Cone Clutch

Editor THE AUTOMOBILE:

[2,764]—I am having a great deal of trouble with the clutch on my car. When

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their automobile troubles, stating them briefly, on one side of the paper only, giving as clear a diagnosis as possible in each case, and a sketch, even though it may be rough, for the purpose of aiding the Editor to understand the nature of the difficulty. Each letter will be answered in these columns in the order of its receipt. The name and address of the subscriber must be given, as evidence of good faith.

I close the clutch gradually it will suddenly seize or bite. It is a cone friction clutch, leather-faced, and has given trouble for some time, although before that it worked perfectly well under all conditions. I would be greatly obliged for any information you could give me as to what the cause of this difficulty may be and how it can be best remedied.

Denver, Col. CHAS. JENKINS.

The clutch pedal should be blocked back as shown in Fig. 2, so that it can be easily examined and the work done to good advantage. If dry, the leather should be soaked with castor oil or neat's foot oil, distributed evenly over the surface. Work the clutch pedal back and forth a few times after the oil has been applied and then block it open and leave it in this condition for about a day.

If the clutch is very oily a good grade of fuller's earth with all grit removed may be employed to absorb it.

Making Preparations for a Long Tour

Editor THE AUTOMOBILE:

[2,765]—I have two Cole model H roadsters, year 1910, 4 x 4 engine. The Cole people state that they have no instruction book covering this type of car and I understand that they have ceased making it. Therefore, I beg to ask of you the following information:

The gears driving the magneto are at the front end of the engine in a case by themselves. This compartment is separated from the crankcase by a felt lining which I can make reasonably tight. Please advise if it is well to fill this compartment full of non-flowing oil or grease or should the regular light cylinder oil be used? There is not much lost motion in these gears, but they make a little noise.

The oiling system of the Cole, as you know, consists of a reservoir in the bottom of the crankcase from which the oil is pumped into two pans. The cranks then take it up. There is a petcock in this pump

What Other Subscribers Have to Say

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their personal experiences for publication in these columns for the worthy purpose of aiding brother automobilists who may be in need of just the information that this process will afford. Communications should be brief, on one side of the paper only, and clearly put, including a rough sketch when it is possible to do so, and the name and address of the writer should be given as evidence of good faith.

which I do not know the use of. It seems to be placed there for the purpose of determining if the pump is working properly. No oil comes out whether it is turned on or off. It may be possible that when this cock is opened air will be admitted to the pump, thereby lessening the flow of oil. Therefore the petcock may be for the purpose of regulating the amount of oil drawn up from the supply. Kindly advise if this is so.

This car is equipped with a leather-faced cone clutch. Please advise proper treatment and oil to use on this clutch.

The transmission gears are in a casing, oil-tight. They are the usual sliding gear type. This case does not leak oil into the clutch compartment, therefore please advise whether light oil or heavy grease is the best to use.

One of the front wheels has been dished by striking something at high speed. The rim normally is flared outward, but since this accident the entire rim is dished inward. Please advise how this may be repaired.

I am preparing this car for a 1,000-mile tour and would greatly appreciate the information. H. R. VAN DEVENTER.

Sumter, S. C.

The gearcase should be packed with a good quality non-fluid oil. The petcock on the crankcase is for overflow in case the oil level is too high, and the reason that you have not had a flow from the cock is probably owing to the fact that the oil level in the crankcase has not been above normal.

The leather-faced cone clutch should be washed with kerosene and castor or neat's foot oil applied. The transmission is packed in a mixture of oil and grease.

If the wheel is much "out of true" perpendicularly, get a new steering knuckle; if horizontally, the adjustment may be made by taking up on the tie rod. For horizontal adjustment the distance between the two wheels at the front and back should tally; for vertical, jack the car up and spin the wheel. If there is an excessive "wobble," the steering knuckle should be renewed. The best thing to do is to let a competent wheelwright examine the wheel.

Not Necessary to Tear the Car Apart

Editor THE AUTOMOBILE:

[2,766]—Would it be asking too much of your engineers to solve a problem for me? I have a small Olds runabout, model "R," single cylinder, made in 1903. If you have anyone who is familiar with this type could they tell me how to put a new wrist pin and bushing in the motor without having to tear the whole car down?

Washington, D. C. J. L. HINES.

Remove the body from the car, take off the front end of the crankcase, unfasten the connecting rod from the crankshaft and draw out the piston. The repairs can then be easily made.

Charging Storage Batteries from Light Circuit

Editor THE AUTOMOBILE:

[2,767]—Will you please give a diagram and instruction for charging storage batteries from an electric-light circuit which is continuous. T. W. L.

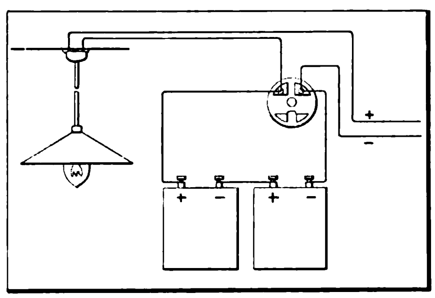

Fig. 3—Wiring diagram showing method of charging storage battery from electric light circuit

Trenton, N. J.

From the switch that controls the lights run two wires as indicated in Fig. 3. After testing which is positive and which is negative, mark the wires in some suitable manner for future use. In order to carry out this test obtain a weak solution of acid or salt water, and after baring the ends of the wires place them in the solution so that they do not touch and it will be seen that bubbles flow from the negative wire. The wires can then be connected to the battery, but care should be taken that the switch is in the off position.

Gear Shift Lever Works Loose

Editor THE AUTOMOBILE:

[2,768]—While driving recently and changing speed the gear shift lever of my car became loose on the shaft, and although it was not bad enough to prevent my getting home, nevertheless I do not feel confident in driving the car until I have it fixed. The shaft is cylindrical and the end of the shaft that passes over the tube is not a very good fit, the two being held together my means of set screws. I should be obliged if you could give me a sketch of a better method of fixing these parts so that my present trouble will not occur again. ARTHUR T.

Philadelphia.

There is very little advantage gained in having this shaft made of tubing and we suggest that the present shaft be replaced by a solid shaft with the end to which the lever is attached finished off in a square in the manner shown in Fig. 4. If the lever is filed in the manner shown and firmly locked with a bolt and nut you need never fear that the lever will shift or work loose. The shaft will have to be slotted in order to accommodate the bolt, but this will strengthen matters and is another means of preventing rotation.

Desires French Automobile Literature

Editor THE AUTOMOBILE:

[2,769]—As I am a reader of your paper I take the liberty to ask a few questions. Where or how may I secure some catalogues of the best known French one-cylinder automobiles or some French and English automobile magazines? I would like to get a catalogue of the one-cylinder racing type Mercedes. C. T. FREDERICK.

Norwalk, Ohio.

The catalogues of the different cars may be had by addressing the manufacturers, who will gladly supply them. The Mercedes car is made in Germany and these people do not manufacture a type such as you describe. An English magazine is the "Autocar," published in Coventry, England, and a French magazine, which may contain the names of the manufacturers desired, is "La Vie Automobile," published in Paris, France.

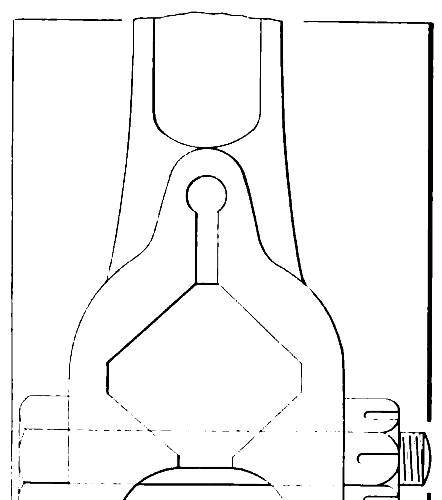

Fig. 4—Method of attaching gear or brake lever so that it will not slip on the shaft

Meeting Recurring Troubles

Presenting a Series of the Most Probable Cases

A series of co-related short stories, accompanied by diagrams and characteristic illustrations, indicating the nature of the troubles that are most likely to happen to automobiles, discussing their causes and effects, all for the purpose of arriving at a remedy. It is the aim, for the most part, to show how these troubles may be permanently remedied, and as a secondary enterprise it is indicated how the automobilist can make a temporary repair, thereby enabling him to defer the making of a permanent repair until a convenient time arrives.

MAGNETO REPAIRING A DIFFICULT UNDERTAKING FOR THE AMATEUR—For the average automobilist who undertakes to repair his own magneto failure is spelled in large letters just about the time he starts on the undertaking. Aimless tinkering never has repaired a deranged magneto, but it has hopelessly ruined many.

If an ordinary bar magnet is placed on a table the magnetic lines of force are constantly flowing from the north pole of the magnet to the south pole. These lines of magnetic force vary in intensity according to the distance from the magnet, and follow the lines shown in the accompanying illustration (Fig. 1). Electric force is generated when the magnetic flow from pole to pole in the magnet is interrupted, and this is the first principle of the magneto. The ordinary magneto consists of two permanent magnet poles arranged in the form of a horseshoe, the ends of the legs of the horseshoe being the two poles of the magnet. The magnetic current runs between these two poles across the gap which separates them. In this gap is placed the armature as illustrated in Fig. 2, where N is the north pole and S the south pole, the armature coil being shown between the two poles. The armature coil is wound about this core and the ends of the wire terminate in the commutator of the magneto.

If a wire is placed between the two poles of the magnet and rotated as is depicted in Fig 3, a current of electricity will be induced in the wire which will have a direction of flow directly opposite to the flow of the magnetic current. As the wire rotates the current will start to flow through the wire in the direction shown by the arrows in the cut. When the wire has turned through one-half of a complete revolution the part which was near the north pole of the magnet will now be near the south pole and the current in the wire, since it is opposite always in direction to the magnetic flow, will be reversed. Since this current is reversed on each revolution it stands to reason that there must be some neutral point just before the reversal where there will be no current passing through the coil. This point is at the spot where the coil is horizontal. The flow of the current may be set out diagramatically as in Fig. 4, the horizontal line being the zero line of no current and the sine curve showing the fluctuations of the current with the change in position of the armature. Three positions of the coil are shown in Figs. 5, 6, 7. These are the positions of maximum current, mean current and no current.

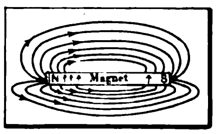

Fig. 1—Illustrating the flow of the magnetic current through a bar magnet

It can be seen that if the core had 2 axes instead of one these current impulses would be more frequent, or, rather, since the windings would be independent, the impulses would overlap each other and give a smoother flow.

The brushes on the armature pick up the current from the coil and carry it to the binding posts of the magneto, whence it is carried by the wiring scheme of the car and distributed to the various points in the system.

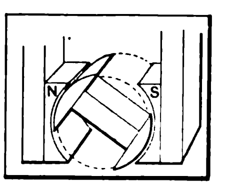

Fig. 2—Position of the armature between the magnets of the magneto, showing direction of rotation

FUEL DIVISION USUALLY TOO COARSE.—In the coarseness of the fuel division lie the chief failures of the typical carbureter. This has been proven again and again by a great many experimenters. Those who have constructed transparent mixing chambers for the observance of nozzle action have invariably found that the fuel left the nozzles as a solid stream or in heavy globules and irregular "chunks," not as a fine spray or mist, as it is supposed to do. Improved design and workmanship on the nozzle or needle valve parts will almost entirely overcome this poor action, with an increase in power output and fuel economy; but any nozzle form used will give a wet and sloppy discharge with low engine demands, even though a true spray may be delivered with increased demands.

Whatever form is given the nozzle, the effectiveness with which it can break up the fuel varies as the difference between the pressures at its two ends, and, as this pressure difference varies throughout the speed range of the engine, the fineness will also vary. At high-speed engine demands the spray will be better and finer than at low; but this is absolutely necessary, since the time allowance for vaporization is less and the quantity of mixture formed is greater.

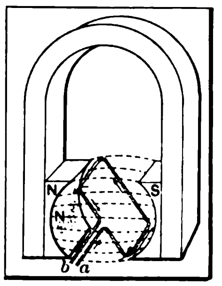

Fig. 3—Showing how the electric current is induced in a magneto coil

The nozzle of average performance will, at medium engine demands, deliver a thin, conical sheet of liquid. This liquid cone is torn away at its edge and carried on by the air column. Some of the fuel torn away is in small enough particles to be considered as spray or mist, and may be taken as contributing directly to the vapor content of the mixture; but the greater part sooner or later strikes some part of the containing walls, from which it is later picked up in the form of globules. These globules are continually picked up and thrown out by the air stream in its progress to the cylinders, until some of them are sufficiently small to become permanently entrained or have been completely vaporized.

Bends in the manifold passages aggravate the expulsion of the liquid globules, but they also permit of fuel once thrown out being readily picked up again. The persistence of rectilinear motion comes into play and throws out the heavier globules at the turns, they being again picked up by a following portion of the air column. This action is repeated at each turn of the mixture lead.

In the foregoing it may seem that the vaporization accomplished by pressure reduction has been placed on a par with that brought about by the heat supply available in the air and passage walls. It is not meant that such an impression be taken. The rate of transfer of heat from the air and walls to the liquid will, of course, be the higher the greater the temperature difference; the lowering of the pressure lowers the temperature of the liquid through partial vaporization, and thus increases the temperature difference. Thus, while vaporization could not go on at a proper rate without such a heat supply, the lowered pressure under which vaporization takes place is an important adjunct, second only to the heat supply.

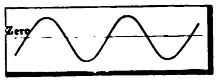

Fig. 4—Diagram showing the fluctuations of an alternating current

DISTINCTION IN VAPORIZATION OF HYDROCARBONS.—Vaporization due to pressure reduction is distinguished from vaporization caused by the supplying of heat. In the former action vaporization can become only partially complete, however far the process of reduction is carried, since the part of the liquid which vaporizes does so through the abstraction of heat from the remainder, which becomes constantly colder, until finally the temperature of the liquid is so low that vaporization ceases until heat is supplied from some outside source. Where vaporization is brought about entirely by heat from some outside source the degree to which it may be carried depends wholly upon the amount of heat supplied, since the temperature of the liquid is being constantly raised to or maintained at the proper point.

In the carbureting device under consideration neither of the above processes is carried to the limit, nor goes forward alone and unmodified. They are called into action simultaneously. The reduced pressure due to motor suction causes vaporization with a lowering of the temperature, and the heat of the air tends to cause vaporization through a transfer of heat from itself to the liquid. Thus it appears that each of these vaporizing actions assists the other—the air supplying heat to the liquid as it is cooled by vaporization under reduced pressure, and the reduction in temperature due to pressure reduction facilitating the transfer of heat from the air to the liquid.

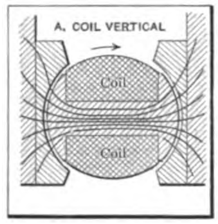

Fig. 5—Magnetic flow with coil vertical. Electrical current at a maximum

Within the temperature and pressure ranges available, the liquid must present, relatively, an enormous surface to the air if vaporization is to be sufficiently rapid. To this end the passage through which the liquid flows is so formed that the liquid is broken up into a spray by the velocity of its effluxion due to the difference between the pressures existing at the two ends of the passage.

In any one carbureter the perfection of vaporization is proportioned to the fineness with which the liquid is broken up at the nozzle. The shortness of the time within which vaporization must be completed is what causes the above factor of fineness of division to enter. Since the heat transfer between the air and the liquid, or the passage walls and the liquid, is effected chiefly through the agencies of convection and conduction—the former implying a rapid agitation and relative motion between the particles of the two substances, and the latter the exposure by the liquid of the greatest possible surface areas—it is readily seen that the finer the fuel division at the nozzle the more rapid and complete will be the vaporization and the greater the homogeneity of the final mixture.

HEATING USUALLY NECESSARY TO VAPORIZE GASOLINE.—If the nozzle and the conditions under which it operates are such that a true mist-like spray is delivered into the air column, no recourse need be had to air or wall heating devices providing the temperature of the air is 60° F. or higher. But, since such conditions very rarely obtain in practice, the expedient of heated air or jacketed mixing chamber walls must often be resorted to.

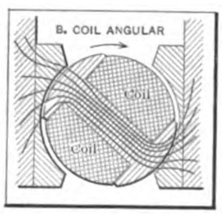

Fig. 6—Magngetic flow with coil oblique. Mean electric potentiality

Because all liquid hydrocarbon fuels are variable and unstable, both in their chemical compositions and physical characteristics, it is very difficult to formulate their actions or determine the best conditions under which to utilize them. Experimental data are placed at an equal disadvantage with mathematical and theoretical analyses in that the exactitude of either method is impaired by the non-uniformity of the substance. However, serviceable figures are entirely within reason; and as such the writer submits the following:

The hydrocarbon known as motor gasoline, specific gravity between .70 and .73, is a mixture of individual substances, each combining carbon (C) and hydrogen (H) in varying proportions. A small percentage of oxygen (O) is often present (never to exceed 3.5 per cent.), but, because of its smallness and sometimes total absence, it will be neglected. The several substances composing gasoline are all of the methane series, the chemical formula for which is expressed C_nH_{2n+2}. This means that for the entire series, which comprises some eighteen substances, each combines C and H in the proportion of twice as many atoms plus two of H as there are atoms of C.

The first member of the series present in gasoline, pentane, C_5H_{12}, has a specific gravity of .626; the last member, decane, $C_{10}H_{22}$, has a specific gravity of .736. The other members between these two have specific gravities ranging between the two values given and corresponding to their increasing molecular weights. The second member of the series, hexane, C_6H_{14}, is the representative constituent of gasoline, being present in greater quantities than any of the others. Traces of pentane or the members beyond nonane, C_9H_{20}, specific gravity .723, are seldom found in gasoline. Thus, hexane, though much lighter and more readily vaporized than the several heavier members occurring with it, should be used as the basis for any calculations. This use is justified by the high vapor pressure of hexane, as will be explained later.

LOSS OF POWER ABOVE 1800 REVOLUTIONS PER MINUTE.—A motor does not necessarily lose power over 1800 revolutions per minute, as there are several motors that give maximum power at speeds well over 2000 revolutions, and some over 2500 revolutions per minute. The maximum speed of an engine is governed by the setting of the valves and the size of the valve seat and outlet ports; as an example, one of the small cars with a 4-inch bore had three exhaust valves to its one cylinder. On engine speed curves of some motors the falling off of power indicated by the falling line is due to the fact that the speed is too great to allow the charges to be either properly gotten to the cylinders, weakness of mixture, or back pressure of the exhaust. It is supposed that the ignition is correct, although, while it is possible to obtain instruments to fire at, say, 3000 revolutions per minute, some do not give satisfactory results above a certain speed, and this can only be determined by trying out several different makes.

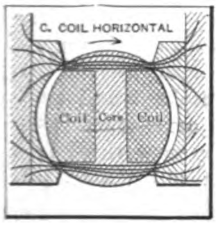

Fig. 7—Magnetic flow with coil horizontal. Zero electric current

DIFFERENCE BETWEEN 2-CYCLE AND 4-CYCLE ENGINES.—In the 4-cycle motor there is one power stroke in each four strokes; there are two strokes per revolution of the crankshaft; valves are used to regulate the inflow and exhaust. In the 2-cycle motor there is a power stroke for each two strokes, and ports are so placed as to admit the mixture and permit exhaust on each down stroke of the piston.

TOOLS FOR REPAIR IN PRIVATE GARAGE.—To the man who likes to keep his own repair shop as well as to run his own car a well-equipped garage is a necessity. Several of the tools to be found in a garage in which the machines are repaired as well as stored are shown in the accompanying illustrations. A small anvil, while not as generally used as the great usefulness of the tool would seem to indicate, will be found on many occasions to be of great use. The anvil is designed to fill the position of a base plate where any hammering on hard metal is to be done. Besides being a mere foundation plate its shape enables it to be used for a bending slab in cases where it is desired to put either a sharp corner on a piece of metal or to fit a part in place by changing the curvature.

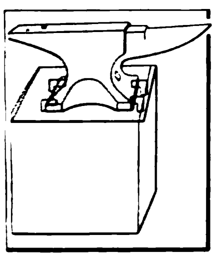

Fig. 8—Usual type of anvil mounted on heavy block and clamped tightly to base to reduce vibration to a minimum

The uses of a vise are so many that it will probably be the first thing that the owner of a machine will find himself in need of if he contemplates doing his own repairing. It is indispensable even for temporary repairs. It would probably be well to have a small and a large vise for different classes of work in a garage that aims to be well equipped for repair work. In connection with the vise a useful part is a pipe bushing which may be inserted when it is desired to thread the pipe or to work it into the desired shape or length. This bushing is fitted with teeth which hold the pipe and do not dent it. The vise can be tilted to any angle at which it is convenient to work, so that when combined with the pipe bushing a very complete and handy tool is given.

A tool which is often used in connection with a vise and connected directly thereto is a drill press. There are two ways in which this tool may be fitted in the repair shop—either by attaching directly to the vise or by having a separate drill press mounted on a base of its own. For the use of a private garage the former is very satisfactory indeed, as it takes up but little room and is large enough for any ordinary use. The part to be drilled is placed in the vise and so adjusted that the drill will strike the desired part of the metal which is being worked. An anvil is often combined with the drill press and the vise and in this way a very useful and compact combination may be had. The larger drill presses may be fed at different speeds, and in this way are adaptable to the metal which is being worked and the thickness of the same. The accompanying illustrations (Figs. 8, 9, 10, 11, 12) show these tools as they are generally arranged.

REMOVING CARBON FROM CYLINDERS BY USE OF KEROSENE.—To remove carbon by injection of kerosene in the cylinders is at the best a makeshift method of removing this objectionable foreign matter. A method that has given satisfaction is as follows, if the valves are not placed in the head of the cylinder:

Turn the engine so that the pistons are on a dead level, and pour through the pet cocks or valve plugs sufficient kerosene to cover the pistons about 1½ inches and allow it to remain in the cylinder all night. A large quantity by the morning will have found its way past the rings into the base chamber. Now take out the exhaust valves and exhaust manifold and turn the engine several times to allow any remaining kerosene to be expelled; turn the engine so that the piston is in position. If you have no such implement, make or purchase a carbon-removing tool, and through the exhaust valve plug or outlet port, if it is placed conveniently, rake out the carbon, which will be soft. The next operation is most important, and it is upon the care with which this is done that the success of the whole operation depends. It will be understood that the inlet valve has not been touched. Take the inlet valve plug out, and what it was impossible to reach from the exhaust side should be pushed toward the latter. Wash out with kerosene from the inlet plug to the exhaust by means of a syringe, and finally with a mixture of kerosene and gasoline, half and half, clean out with some fresh rag, but always see that the inlet valve of the cylinder that is being worked upon is closed. It is advisable when the pet cock is placed in the head of the cylinder to remove same and pass a wire down it, as the orifice often becomes clogged with carbon, and although the piston and cylinder are clean the carbon in the cock becomes incandescent and causes pre-ignition. It is preferable to pour the kerosene into the cylinder direct rather than to take it in by way of the induction pipe.

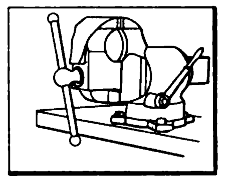

Fig. 9.—Illustrating vise mounted on work bench

As regards the lubricating oil, the base chamber should be emptied and fresh oil inserted before running the engine and it will be advisable to insert a small quantity of lubricating oil in the cylinder as well. This can be done through the valve covers, first allowing the piston to go below halfway down, and by this means pouring the oil on the walls instead of on the piston head.

Inserting a small quantity of kerosene through the pet cocks after every 300 miles should help to keep the engine clean. Some piston heads are turned rough, and will pick up carbon quickly. If this is so in your case, much trouble can be avoided by taking them out and having them polished smooth.

ALTERING THE COMPRESSION OF A MOTOR.—When it is desired to increase the compression the most general method is to attach a plate to the head of the piston. This, however, has the distinct disadvantage, especially for a single-cylinder motor, of upsetting the equilibrium. To overcome this it is necessary to touch up the flywheels, which generally carry counterweights. For a four-cylinder motor the inconvenience is less, except in cases where the motor is balanced cylinder by cylinder. There is still the disadvantage of an increase in the weight of the reciprocating parts which is likely to reduce the number of revolutions per minute. A more mechanical method is to machine a special piston with a dome-shaped head. This, however, is a costly procedure. A cheaper method is to make a new and longer connecting rod. If the compression has only to be slightly increased a clever smith can lengthen the connecting rod by heat treatment. This, however, is a delicate operation. Compression can be slightly increased by machining the valve plugs until they penetrate further into the cylinder. The angles should be rounded off in order to prevent pre-ignition, and naturally enough space should be left to allow of the normal lift of the valves. A method often employed is to plane the lower face of the cylinders, or the upper face of the crankcase, thus bringing the head of the piston nearer the top of the cylinder.

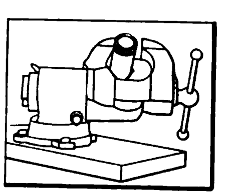

Fig. 10—Showing an ordinary vise with a pipe-holding bushing inserted

Compression may be decreased by the use of dome-shaped valve plugs; by changing the piston for one with an incurved head, or by putting a plate between the bottom of the cylinder and the crankcase. Although compression can be increased by placing a metal plate on the top of the piston, the contrary cannot be done to decrease compression, the piston generally being so thin that any planing of its surface would rob it of necessary strength. It is not advisable to change the connecting rod, for there will be danger of the lower part of the piston touching the top of the crankcase. If the metal is taken off the piston to overcome this the balance of the motor will be destroyed.

FORESIGHT NECESSARY IN PURCHASING TOOLS.—It is not very hard to fill the garage and automobile full of useless tools, yet it is a thing which can be prevented with the use of a little foresight. Taking the matter of wrenches, for instance, a double-ended wrench may be purchased which, if the specifications given to the dealer are correct, will cut in two the number of wrenches carried. It is a very common occurrence to find a machine carrying wrenches, one end of which will fit a bolt located on a part which needs occasional adjusting while there will not be a nut on the car which can be turned by the other end of the wrench. The cut shown herewith (Fig. 13) illustrates a common form of straight wrench with which the average automobilist is no doubt very familiar, since it forms part of the equipment of nearly every car. To set out upon a trip, however short, with an inaccessible nut upon the car is to invite unnecessary delay, but the tool supply should be so designed as to reach everything in reason and yet be as compact and light as possible. It is not desirable to carry an S wrench where a straight wrench or a 15-degree wrench will do the work, as it takes up more room and is no more satisfactory in the way of additional leverage. A very handy thing to have in the garage in connection with the larger wrenches is a short length of pipe which will fit over the wrench. This is only of use, however, where single-ended wrenches are used.

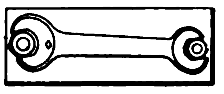

Fig. 13 — Illustrating an ordinary form of wrench, generally a part of the equipment of the car

COMPOSITION OF PRODUCER GAS.—The average gas from anthracite coal has a thermal value of about 135 British thermal units per cubic foot, and the various constituents by volume are: Carbon dioxide, CO_2, 6 per cent. Carbon monoxide, CO, 24 per cent. Hydrogen, H, 15 per cent. Nitrogen, N, 55 per cent. Also methane, CH_4, trace. Oxygen, O, trace. Producers may be made in quite compact form and the fuel required per hundred miles of travel is not so much that it would more than serve as ballast for the tractor.

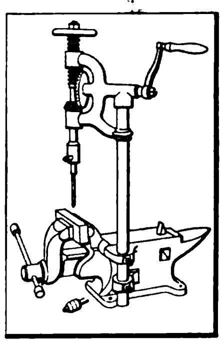

Fig. 11 — Drill press, vise and anvil mounted all in one, making a compact set of tools

THE REAL CARBURETER. — The accepted type of carbureter, taken together with its distributing manifold, forms a surface carbureter usually of quite small surface. The manifold walls form the real carbureter, and the device called the carbureter furnishes the fuel to that surface, from which any proper vapor that may exist in the final mixture is carried by the passing mixture of air.

By "typical carbureter" is meant a device in which liquid fuel is brought into contact with a moving column of air by the same pressure depression which causes the air to flow, *i.e.*, it is drawn through a passage by the motor suction simultaneously with the influx of the air with which it mixes to form the explosive mixture.

In the "typical" device, fuel is carried by flowing air from the open end of a passage located in a region of pressure lower than that of the atmosphere to which the other end is open. Lowered pressure without a correspondingly lowered temperature tends to cause vaporization. It is undoubtedly true that vaporization starts at this point as soon as the fuel has fairly left the nozzle. The intensity of this action depends upon the extent to which the pressure is lowered. The pressure reduction about the nozzle may be taken at .5 pounds per square inch, which value increases through the manifold to the valves until it reaches a value of 6 to 8 pounds with some six-cylinder engines.

Short Stories of Current Interest

Unraveling the Puzzling Situations

It is pointed out that the greatest puzzle probably lies in the fact that good examples are scarcely ever taken advantage of in a timely way, whereas bad examples seem to have a free pass into everything and go unchallenged until the purchaser no longer indicates a desire to support the issue.

IN the building of automobiles, as in the making of other machines, there are certain practices that are sanctioned by mechanicians of experience, and there are certain other practices that have failed to obtain the sanction of authority. Take, for illustration, the use of tapered pins to the exclusion of keys in the joining of rotative members or the members that have to resist torsion; it is not a sanctioned practice, nor can it be, due to the fact that no reliance can be placed upon taper pins under such conditions. In the face of this fact there are designers who harbor the impression that if one taper pin in the absence of a key is a bad thing to use two taper pins should be considered satisfactory. This way of thinking certainly offends logic, and in nine cases out of ten if logic departs the sweet-running qualities of any automobile made in its absence will take wings and migrate to a more agreeable situation. In the meantime there are considerable numbers of automobiles that have their rotative members joined by means of keys with taper pins so placed as to prevent the members from floating away from each other, but even this plan is frequently insecure, due to the fact that the keys loosen up during the course of time and the taper pins are then sheared off, making a nasty mess out of the situation, if nothing worse.

It Is Extremely Difficult to Understand Why Taper Fits Are Abhorred in Many Quarters

Of the available ways for fastening hubs and other like members on shafts and spindles, taper fits, in the absence of flanges, are the most secure, and parallel fits are not only the hardest to make but they are also the most insecure. The probabilities are that many operators in machine shops are so lacking in skill that a taper fit and the method of its production is beyond their understanding. A little study on the part of those who are unfamiliar with the niceties of taper fits will lead them promptly to the conclusion that there is no more difficulty attached to the machining and grinding of tapers than there is to be encountered in the machining and grinding of parallel surfaces.

If a taper fit is to be made and it is desired to press a hub after it is suitably tapered onto the taper of its mating shaft, the average man balks because he does not understand how to caliper the taper and obtain the desired accuracy. In the meantime, if the taper is made on a basis of 3-16 of one inch to the foot, a little computation will show that a variation of one-thousandth of one inch in the diameter of the taper is equivalent to a movement of 1-16 of one inch of the tapered hub upon the taper of the shaft.

Taper fits are easy to make because the limits of tolerance may be fixed upon a liberal basis, and they are easy to measure because there is a definite relation between any change that may be made in the diameter of the taper and the distance that the members will fetch up on each other due to changing diameter. As an illustration of the limits of tolerance that may be permitted when taper fits are indulged in, it is enough to say that for a two-inch shaft, if a press fit is desired, the limits of tolerance may be from 0.006 to 0.007 of an inch, and if the taper is finished on a grinding machine the operator who would have difficulty in keeping within these limits of tolerance can scarcely be looked upon as a fit talent to employ in work of this character. It will of course be remembered that the limits of tolerance that can be indulged in under fitting conditions of practice are a variable depending upon the diameter of the taper, and to illustrate this point attention is called to the allowable limits of tolerance if the taper is eight inches in diameter instead of two inches in diameter. In the latter case the limits of tolerance may be from 0.012 to 0.013 of an inch. For other diameters the limits of tolerance are changed in proportion to the taper dimensions.

Authorities Differ as to Tolerance Limits

In the face of the fact that the questions of tolerance have been discussed for many years, it still remains to be said that no two draftsmen seem to agree with each other, and even among the engineers of quality there is a wide difference in opinion respecting this important matter. One company under the direction of a eminent engineer worked upon this phase of machine building for 30 years, and at the expiration of this time the engineer in question was able to say: "Despite the fact that I have perfected a tabulation of limits of tolerance, taking 30 years to do so, I have never known of any engineer who was willing to risk his reputation by copying the practice that I have thus introduced into the plant over which I preside, and this is in the face of the fact that success has attended my effort." This was not a case involving a desire on the part of this engineer to inflict his ideas upon his brother engineers, but in looking around and observing the performance of machines in general as they come from many plants it was easy enough to see that a large measure of the troubles experienced during the construction period and later in service came from poor fits, and it is conceded by almost every engineer of experience that the great question is to limit the errors that machinists made so that the parts will mate with each other, and the real limit to fix for these errors is founded upon the idea that absolute perfection in the making of parts is an utter impossibility and that "neat" fits must rank as a theory, so that the underlying principle that guides the maker of a machine is based upon "error" and the remaining question is, How much shall the error be?

There are other considerations attending the fixing of the limits of tolerance in the mating of the members that go into an automobile; whether or not the limits are to be plus or minus or plus and minus must be worked out depending upon the influences of the several situations, but the fundamental principle underlying this part of the problem is based upon the "tendency." If, in machining a part, the tendency is to make it undersize the limits of tolerance should be plus; if the tendency is in the direction of an oversize it would then be fair to oppose this tendency by making the limits of tolerance minus. If the facilities are such that the limits of tolerance might be approximated with much certainty, the limits of tolerance may then be on a basis of plus or minus, splitting the limits in half. In the assembling of parts that are not made all in the same plant the limits of tolerance for the parts that have to be made in the plants should be so contrived that they will favorably react in view of the tendencies for error as they are likely to obtain in the parts that are purchased outside.

Some Facts as to Skidding

A careful manipulation of the steering wheel can often be made to overcome a very dangerous attempt to skid on the part of either the rear or front wheels. Or the skidding itself can be used to prevent the more dangerous side-slip of the car.

EITHER the front or rear wheels are liable to slip sideways if the driver attempts to alter the direction of travel suddenly on a greasy road. Rear or driving wheels when driving are more likely to lose their grip on the road than those which are rolling freely. A spinning wheel or one which is locked will often lose its individual direction of travel and become simply a point of contact on the road. From this it will be seen that side slip is usually experienced with the rear wheels and depends on the application of the brakes and the care in driving, and that it need not necessarily result from taking a turn too rapidly or too sharply. This can be shown by driving a car along a greasy road and applying the brakes with sufficient force to lock the rear wheels. The car will immediately tend to turn end-for-end upon the road and even if the road is not greasy a sort of side slipping is set up, which can be corrected by the steering gear, in causing the front of the car to move sideways in unison with or to a greater extent than the rear wheels. If the rear tires cannot obtain any grip on the road, as they are being dragged over its surface the rear of the car is apt to swing around too quickly for the driver to check such a tendency in the brief time available. Side slips of this character can only be checked by either releasing the brakes and thus freeing the wheels or by causing the front wheels to keep the car parallel with the road as soon as the first signs of slip become apparent, since once the rear of the car has swung around to any extent the driver is powerless to bring it in position again by the manipulation of the steering gear. The wheels need not be actually locked in order to bring this about; all that is needed is for them to lose their grip on the road and this occurs when they revolve at a slower peripheral speed than that of the car or when driven at a higher speed than that at which the car is moving.

Dilution Arrests Combustion—Four parts of nitrogen are drawn into the cylinders of an internal combustion motor with each part of oxygen. This nitrogen is not only useless in increasing the effects of the burning, but, on the contrary, it is a positive deterrent, since it dilutes the oxygen to such an extent as to neutralize much of its desirable effect. If the proportion of the nitrogen could be reduced, the burning would be correspondingly more rapid, with the consequent more rapid expansion of the gases formed, which would result in more powerful impulses being delivered to the piston. One method of reducing the proportion of nitrogen is to increase the proportion of oxygen. This has been done many times by mixing certain substances with the gasoline. A substance, to be of value in this connection, should have the following properties: it must contain a fair proportion of available oxygen; it must decompose readily into its constituents; it must be soluble in gasoline; when burned in a closed space it must not leave a liquid or solid residue, and the products formed by burning it must have no injurious action on the metal of which the engine cylinders are made.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

WRITING of the "state of the art" cannot be undertaken at this time without observing that many of the things that are done automobilewise are too crude to be commended; they must be dragged from their hiding places and cast into the pit of condemnation. In THE AUTOMOBILE for this week are reproductions from photographs showing a defective starting crank and the lacerated hand of the gentleman who undertook to start the motor. It is a queer place to locate knife-blades or the equivalent, which is what it amounts to when the profile of the handle of the starting crank is bounded by sharpened edges, and, remembering that infection of the most virulent sort is likely to be planted upon the handle of a starting crank by some person unawares, it merely remains for the owner of the automobile to have his hand lacerated in the cranking process when he will catch the infection and become a victim of the crude mind that thinks it is building automobiles when in all fairness a true estimate of any such product is not to be described in sanctioned language of any tongue.

* * *

AMONG the improvements that have yet to be made in the building of automobiles, a testing equipment which will locate the inharmonious location of the units to each other is necessary, and few indeed are the automobilists who are in a position to testify to the acumen of designers from this point of view. It is all very well to design and construct a good motor and to make it pass a dynamometer test before it goes into the chassis, and it is a fine thing to rig up an instrument for determining the abstract capability of the live rear axle, and another device to find such troubles as may reside in the transmission gear. But when these individual tests are conducted to completion and the units so tested are planted in the chassis frame there are a hundred reasons why they may not work in harmony with each other, and, unfortunately, it is the purchaser of the automobile so made who has to cope with the resultant disorders.

* * *

EVERY builder of automobiles will contend that a road test will develop any lack of harmony that may be present in a car after the tested units are assembled and the automobile is sent out upon the road in the hands of the tester. Looking at this situation from another angle makes it possible to point out that the chief engineer and the corps of experts who are so fond of telling what they do are really subordinate to the tester, under such conditions. The chief engineer is only responsible for the design, construction and testing of the individual units, and the "tester" must be given credit for fixing the relations that result in harmony of performance, if by any chance this desirable condition creeps into the aggregation, but if the great designers of the units are willing to admit that the tester measures far short of their capabilities the wonder is that they would be willing to assign to him the task of harmonizing the relations of the units and placing at the disposal of the buyer of the car a silent and flexible performer.

* * *

FURTHER evidence of great activity in the field of motor designing continues to appear in the pages of THE AUTOMOBILE from time to time, and it is almost a moral certainty that the patrons of the industry will become somewhat confused in their ideas if they attempt to choose between these types of motors, or if they serve as the "jury" in the process of arriving at conclusions, rendering a snap-shot decision. Almost every example of piston and slide-valve motors that is now being brought out in the guise of something new and wonderful has been tried in one way or another heretofore, and the only question is, Are the men of to-day so much more skilled in the art that they can gain success in its fullest measure on the very battle ground that brought abject failure to the designers of yesterday? That the art has advanced many measures in the course of a few years is quite too true to merit further discussion, but there are limits beyond which skill in its most refined form, supported by ingenuity in all its ramifications, will fail to penetrate. The patrons of the automobile industry can well afford to lay back in the tonneau seat of a well-made automobile of to-day, listen to the purr of a fine-spun motor, even of the poppet-valve type, and await with equanimity the proof that is now lacking of the newer facts as they bear upon utility, so that when the proper time comes they may compare the products of the several schools of design on a basis of equity and see for themselves which is the best for their needs.

Special Fire Board Working Hard

Committee Considering Specifications

Technical body of the Fire Department is compiling a set of specifications to be followed by the manufacturers of automobiles and fire apparatus in competing for the contract to motorize the New York department. There is $700,000 available for the purchase of fire equipment at present and much more may be added to that sum. Makeshifts and patch-work are to be at a discount in filling this contract and the whole effort of the department will be directed toward securing the best results.

WORKING full union hours, the special board named by Fire Commissioner Johnson to motorize the New York fire department is about the busiest committee in the municipal government of New York City. Under the direction of Deputy Commissioner Farley, the board is holding daily sessions at headquarters. Chief Kenlon, of the department, who was named for that position Tuesday noon, Chief John P. Howe and Captain Demarest are the colleagues of the Brooklyn Deputy Commissioner.

Commissioner Johnson is impressed with the idea of improving the service of the department and has instructed the committee to use the utmost diligence in deliberating upon the questions that come before them. He believes that makeshifts are uneconomical and that the perfect fire-fighting apparatus should be a complete whole rather than an assemblage of an automobile and one of the various bodies useful in the work of the department.

In the past sets of specifications for both automobile and fire department bodies have been prepared without plans and drawings and bids have been asked from manufacturers. Some of the apparatus submitted has been good as an automobile and more of it has been good as fire-apparatus, but experience has been plentiful to show that much of the mechanism tested has not proved to be satisfactory as automobile-fire apparatus.

Where specifications have been offered, the bidding has not been sufficiently general to afford the widest choice. The manufacturers of automobiles sometimes have been required to make unusual alterations in their stock models in order to come within the terms of the specifications and, of course, were obliged to rely to a greater or less extent upon the manufacturers of fire apparatus or some of their equipment. The makers of fire apparatus naturally have an advantage in the bidding for bodies, but this is counteracted by the fact that they are not manufacturers of automobiles in a broad sense.

The situation as it has now been developed is that the fire department is looking for apparatus driven by gasoline engines that shall be symmetrical in service, utility and appearance.

It is pointed out that only a small mileage is required of motor fire apparatus in the course of a year. This mileage must be accomplished at high speed and with the utmost certainty. While it is known that wear and tear on an automobile increase as the square of the velocity, the fact remains that fire apparatus has much labor lavished upon it in its periods of rest.

For instance in some of the outlying stations there are few calls in the course of a year, one in a month being a liberal estimate. Now, during all the time except for the few hours or minutes in which the engine is fighting the flames, it stands in its house, the central object of the care and attention of a whole company. Thus it is a simple matter to maintain an automobile fire engine in the highest notch of efficiency and the fire department in buying such engines does so in the belief that they will last for many years.

The trouble met with in the past has been that numerous makers are able to comply with the measurement requirements and that few of their products have been able to meet the service tests. It is the main object of the board to compile such a set of specifications that when the apparatus is submitted it will cover the ground of the practical tests. Deputy Commissioner Farley has formulated a report covering this point and in the course of a few days it will go to the commissioner for action.

It is the intention of the department to conduct an automobile school for the purpose of training expert drivers and mechanics.

Garden to House Its Last Show

According to official announcement the automobile show which will be held in Madison Square Garden from January 6 to 20, 1912, will be the last ever to be held in that historic structure. The reason for this state of affairs is not that there will be no more automobile shows of the size reached by recent shows in the Garden, but because the Garden itself is about to be razed to make room for a gigantic office building.

But the show will be held in January and it is predicted by those who will be in charge of it that it will exceed in size and importance anything in the way of an automobile show ever staged in that building.

It will be a two-part show as was that of 1911. The pleasure vehicles will hold forth from January 6 to 13 and the trucks will be on exhibition from January 15 to 20. The same exhibition committee as last year's will be in charge, comprising: Col. George Pope, chairman; Charles C. Clifton, Alfred Reeves and Merle L. Downs, secretary.

The only way the show of 1912 will differ from that of 1911 will be in its contemplated size. Application blanks for space will soon be issued and allotments will be made shortly.

Whiteside Heads Stevens-Duryea

CHICOPEE FALLS, MASS., July 31—At a meeting of the stockholders of the Stevens-Duryea Company, July 29, W. H. Whiteside was elected a director of the company. There was also a meeting of the board of directors held, at which Mr. Whiteside was elected president of the company to fill the vacancy caused by the resignation of Irving H. Page. Mr. Page was at the same meeting elected chairman of the board of directors and treasurer of the company.

Fair Card at

Mercer Wins Four

Remy Brassard changes holders, but remains in same control. Small fields and lack of sharp competition in races are overlooked by big and enthusiastic audience at mid-summer meeting of the Quaker City Motor Club at Point Breeze track. Stock car events find no place on program. Track record is cut about a second in the mile trial. Opel car makes its bow to American public in races.

PHILADELPHIA, July 29—Approximately 10,000 enthusiasts witnessed the running of the card of races at Point Breeze track this afternoon, the occasion being the annual mid-summer meeting of the Quaker City Motor Club. The Remy Brassard, which was won by the Blitzen Benz (Burman) at Brighton Beach, July 4, was transferred to the Mercedes (Knipper). The ownership of the trophy and prize, however, was not altered, as both cars and both drivers are controlled by the same interests.

The first event of the day was a ten-mile race in which three cars were entered, and developed into a procession soon after the start, a Buick (Brennan) opening a wide gap over its opponents, an Abbott-Detroit, W. P. Padula, driver, and a Metz, piloted by Harry Baker. At the conclusion of the 6th lap the Buick was leading by half a mile, a lead that was further increased as the race progressed, winning in hollow style.

The one-mile exhibition for the Point Breeze circular dirt track record was next carded. After a preliminary tuning-up spin around, Burman signaled that he was ready and the Blitzen Benz completed the circuit in 58 4-5 seconds.

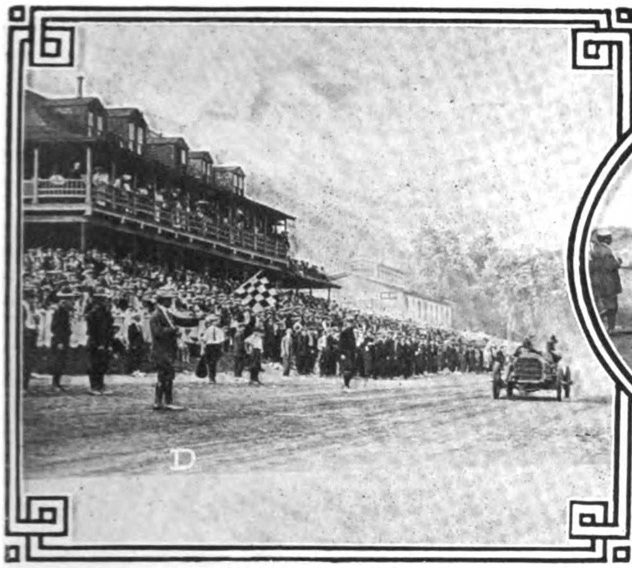
In the second event, after the second mile, the Mercer (Ringler) had all his own way. It, too, was a 10-mile race and drew four entries. During the course of the race the winner lapped both the Staver-Chicago, and Klinekar, which finished second and third respectively. The time made was the best of the day for a ten-mile event, 11 minutes 17 2-5 seconds.

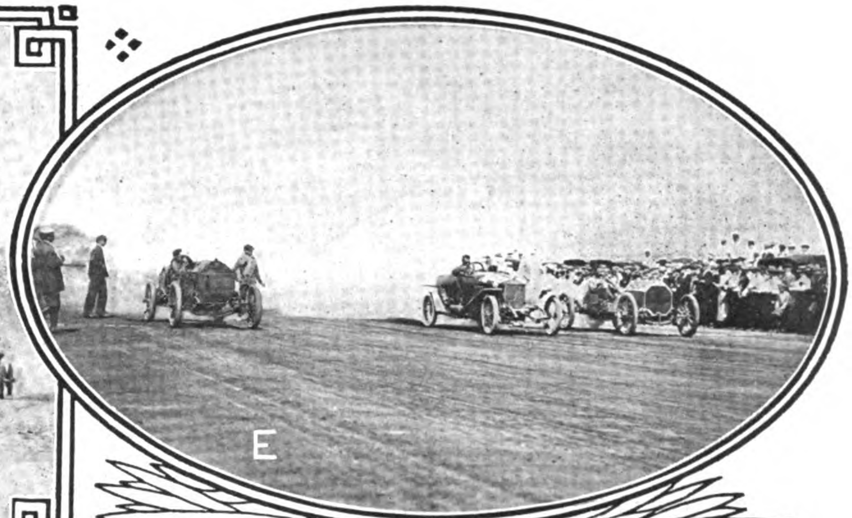
The third race saw the introduction of a freak machine in the shape of a cigar, even to the band encircling it. It was an Opel car, driven by Richter, and had as opponents a Jackson car driven by Harry Cobe and a Klinekar. The last-named car threw a tire on the fifth lap and the race developed into a two-car affair, the foreigner winning in 12 minutes 19 4-5 seconds.

Next run off was a substituted special race between five cars. Right at the jump the Mercer (Hughes) developed engine trouble and was forced to retire from the track. In the meantime Mercer (Ringler) opened up a big lead and the other contestants, Du Closne in a Staver-Chicago, Winkler in a Klinekar and Brennan in a Buick kept plugging away, and the spectators were surprised when Hughes reappeared and essayed the apparently hopeless task of catching up, finishing second.

In the contest for the Remy Grand Brassard and Trophy, Burman and Knipper, the former piloting a 110-horsepower Benz and the latter a Mercedes, cut out a record-breaking pace for the first two miles, at the end of which the Opel (Richter), the only other contender, was trailing half a lap in the rear. The Benz and Mercedes passed the judges' stand almost simultaneously in the second and third laps. Nearing the homestretch on the fourth mile, Burman was seen to slow down and finally stop altogether, his chance gone by reason of a broken feed pipe on the Benz.

The 10-mile handicap was won by the Mercer (Ringler) in





D—Mercer, Ringler driving, winning the ten-mile handicap

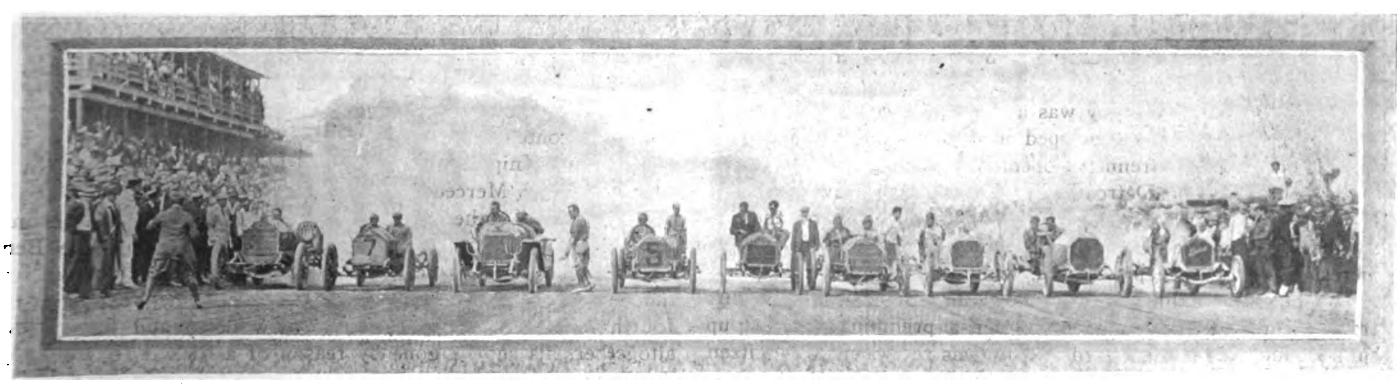
Twenty-Five Mile Combination Race

5	Mercer	Hughes	1	27.24%
4	Mercer	Ringler	2	.....



Line-up in Event No. 7—Buick, Klinekar, Klinekar, Mercer, Metz, Mercer, Opel, Abbott-Detroit, Jackson

Big Fields in Elgin Races

Stock Car Contests Draw Many Entries

Course for National Stock Championship events has been carefully improved and prepared for the four races that will be held August 25-26. The homestretch has been widened, grades cut down and turns made safe in anticipation of the greatest exhibition of its kind ever held. The average width of the course has been increased at least fifty per cent. over last year and as at present arranged, three cars can move through the stretch on even terms.

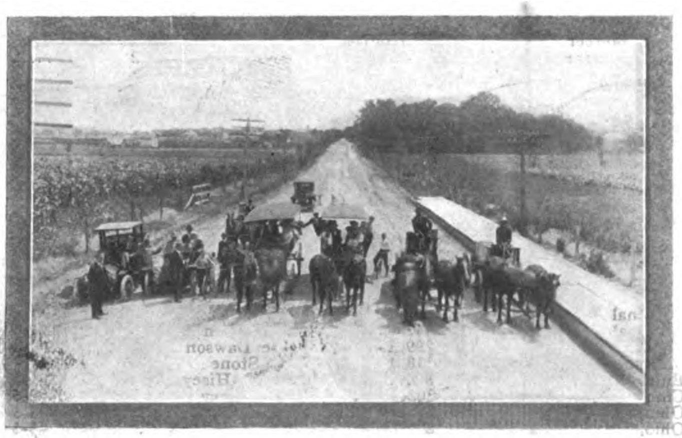
CHICAGO, July 31—With twenty-three entries already made in the four big road races that will be run off at Elgin, August 25-26, the prospects are favorable for holding the national stock car championship races under highly improved circumstances.

The course is 8 miles 2,499 feet around and has been prepared for the races with much care. Elgin has spent $4,000 on the homestretch, which has been widened from 16 feet to 54 feet. Britten's hill has been cut down to a considerable extent and the gravel resulting from the cutting operation has been used in the work on the stretch.

Udina turn at the southwest corner of the circuit has been entirely remodeled. Last year it was a dangerous curve but now it looks as if a car could make it almost at full speed. By cutting into the field on the inside, the road at this point has been widened to 100 feet, an easy swing which gives the drivers plenty of elbow room. The telegraph poles have been moved back from the road and every precaution taken to make the turn safe.

The west leg of the course was a country lane a year ago but now it is one of the best parts of the course. It is a mile in length. The McQueen turn at the northwest corner of the course which will swing the races into the west leg going south also has been improved. Instead of cutting into the bank much the work has been done on the outside.

The east and north legs also are in rare condition. Starting at Hornbeek's the east leg is only a short dash to McLean's corner. At the latter point the owner of the property has given permission for the course to cut across his lawn in order to make a wider turn at that place. This will swing the racers into the backstretch which angles into the northwest and which last year was the best part of the circuit. It has been improved if anything and in many places is wider than before. The foundation of this road is good and it required little work to put it into condition for the race.



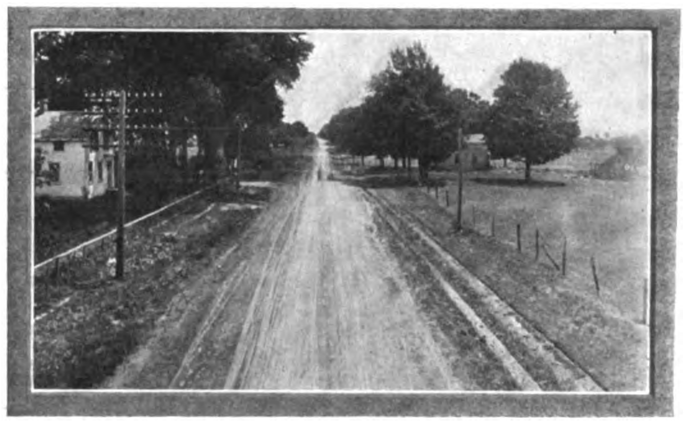
The homestretch in front of the grand stand will be 54 feet wide, insuring ample room for three cars abreast

As the course is at present it will average 24 feet in width for the entire circuit whereas in 1910 it barely showed 16. The turns have all been given attention and the only one that has not been widened is at Hornbeek's. There the outer edges of the four corners have been so improved that the turn is much safer.

At present the Elginites are engaged in oiling the course. Up to yesterday 24,000 gallons of oil had been put on and there yet remain 50,000 gallons before the work will be completed. Last year only 44,000 gallons of oil were used and yet the course was dustless. Getting such a start this time, the oil will be permanently set before the circuit is turned over for practice.

The work of constructing the grandstand has not started as yet, but this will not delay matters any. The stand this year is to be 650 feet in length and capable of seating 6,600 people. The boxes will be placed at the top of the stand and will be covered.

On the inside of the course at the tape will be located the judges' stand, the press stand, a covered stand for invited guests, the hospital tent and the official cars. The scoreboards will be placed on top of the press stand which is 60 feet in length and capable of accommodating 200 newspaper men. In addition to the main score board there will be others placed around the circuit, the farmers having stipulated in their contract with the Elgin association that there be a scoreboard each mile of the course.



Magnificent level straightaway on the backstretch where fast time will be made

The races will start at 11 instead of 10 o'clock. Where the course was closed at 9 o'clock last year, this time the spectators will have until 10.40 to get to their places. Occupants of parking spaces will have until 10:30 to get to their locations.

The honorary referee will be George E. Hunter, of Elgin, representative of the Elgin Watch Company, which gave the Elgin National trophy. The referee will be David Beecroft, president of the Chicago Motor Club. Honorary judges include: R. P. Hopper, Carter H. Harrison, mayor of Chicago; George Tiedeman, mayor of Savannah, Ga.; Harvey Granger, president Savannah Automobile Club; C. H. Hurlburd, president

Elgin Watch Company; W. E. Metzger, president National Association of Automobile Manufacturers; S. A. Miles, general manager National Association of Automobile Manufacturers; Charles Clifton, president Automobile Board of Trade; Carl G. Fisher, president Indianapolis Motor Speedway Company; Asa Candler, president Atlanta Automobile Speedway Company; Hugh Chalmers. Detroit.

The active judges will be: N. H. Van Sicklen, Sr., Chicago Motor Club; Everett C. Brown, president Amateur Athletic Union; T. J. Hyman, Chicago Automobile Club; Allen S. Ray, Chicago Automobile Club; W. Rufus Abbott, president Chicago Athletic Association; Walter Egermann, Aurora Automobile Club; H. B. Hemens, president Elgin Automobile Road Race Association; W. C. Thorne, Chicago Athletic Association; Thomas J. Hay, Chicago Motor Club; Henry Paulman, Chicago Motor Club; James E. Plew, president Aero Club of Illinois;

The turn at Udina, formerly the worst on the course, has been widened to 80 feet

Harold McCormick, vice-president Aero Club of Illinois; J. K. Stewart, Chicago Motor Club; Frank W. Wentworth, Chicago Athletic Association.

In recognition of the generosity of the Aurora Automobile Club in donating the cup for the 161-230 class on the first day it has been decided to call that trophy the Aurora cup instead of the Fox River.

Up to Monday there had been twenty-three nominations made for the four races, the last ones to register being two Simplexes, two Velies, an Abbott-Detroit and a Pope-Hartford. The list to date is as follows:

Elgin National (Under 600 inches)—Lozier, two Nationals, three Alcos, two Simplexes, and Pope-Hartford.

Illinois Cup (451-600 class)—Two Nationals, two Velies.

Kane County Cup (231-300 class)—Three Falcars, three Staver-Chicagos, two Coles, three Colbys and Corbin.

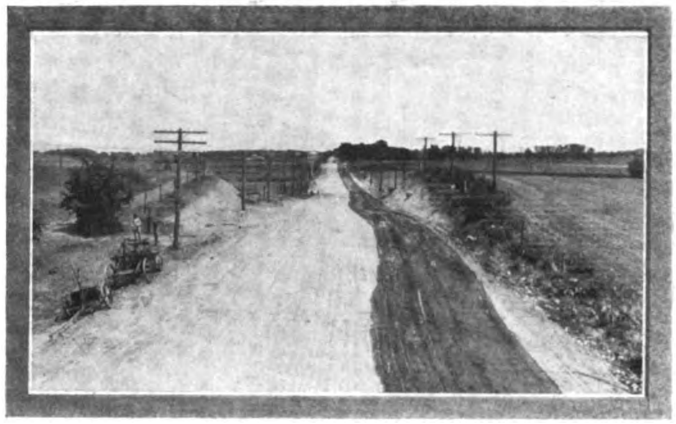
Aurora Cup (161-230 class)—Abbott-Detroit.

Dead Horse Hill Climb August 12

WORCESTER, MASS., July 31—First among the hill climbing contests in the East this year will be the annual event of the Worcester Automobile Club on Dead Horse hill, August 12. Entries are coming in early for the climb and the latest contestants to be enrolled are two Simplex cars which will be handled by a pair of skillful amateur drivers. So far the list is well advanced and the event promises well-balanced fields and keen competition.

The hill is being given a thorough preparation for the climb and the club members believe it will be in better shape this year than ever before. The record for the hill is held by a Stanley Steam Car driven by Baldwin in 1908 and stands at 54 seconds. A Fiat holds the gasoline record in 58 seconds.

The hill is exactly one mile long and is perfectly straight. It starts on the flat and dips slightly immediately after crossing



Showing how Britton's Hill has been cut down. Note the beginning of the oiling process on the right

the line. From the end of the dip it rises sharply in a series of heartbreaking jumps to the summit.

Owing to the fact that this year hill-climbs are rather rare everywhere in the country, the Worcester event is attracting much attention. Last year the meeting was one of the best run off and the program contained a series of stock car contests that developed some interesting climbs.

Nationals Win at Cincinnati Climb

CINCINNATI, O., July 31—Safe, sane and sensible was the automobile hill climb in this city yesterday afternoon. It was directed by the Cincinnati Automobile Dealers' Association and not a mishap marred the afternoon's sport. The Stanley Hill course was 2,340 feet and had a grade of 11 per cent. and all events had flying starts.

First honors went to the National cars, winning three firsts. The Cino and Ohio, Cincinnati products, gave a splendid account of themselves.

The summary:

Car.	Piston Disp.	Driver.	Time.
	Class C. Non-Stock

Routing Good Road Tourists

T. C. A. Selects Path to Richmond

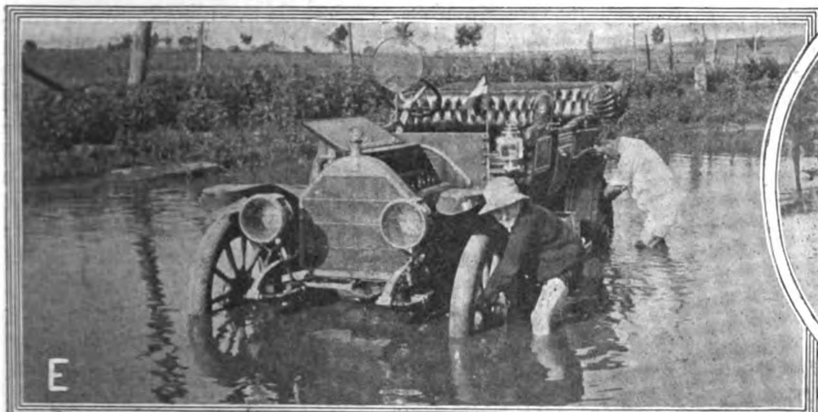
Three cars carrying the pathfinders of the T. C. A. were engaged in the recent trip from Washington to Richmond, where the national convention in the interest of good roads will be held next Fall. The trip is graphically described and the preliminary work for the convention is outlined. Distinguished party accompanies the pathfinders, foreshadowing the great importance of the convention and the interest that it is attracting already.

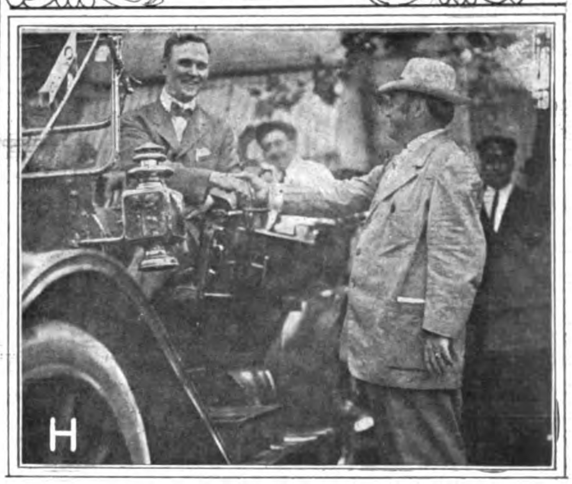
WASHINGTON, D. C., July 31—Unquestionably, good roads are of first importance from an automobile viewpoint, and when the pathfinders of the Touring Club of America blazed a trail to Richmond last week they started in motion a vast machinery which is destined to result in benefit to the motoring public.

The party which consisted of three cars left the southeastern branch of the Touring Club of America in the Colorado building, at 10.30 a. m. on Monday, Vice-President Sherman being on hand to bid them godspeed. Mr. Sherman is an enthusiastic motorist and the honorary chairman of the advisory board of this branch of the T. C. A. In the first car, a Velie Forty, Charles E. Miller sat at the wheel with H. E. Duckstein of the Washington *Post,* Howard Fisk of the Washington *Star* and S. S. Grogan of the Washington *Herald*. In the second car, a Packard thirty, Lee A. Folger of the Gordon Motor Company was at the wheel, and Henry MacNair, editor of the *Automobile Blue Book,* sat on the front seat.

In the rear were Hon. Paul D. Sargent, acting director of public roads and Capt. P. St. Julien Wilson, Virginia State highway commissioner. The third car was manned by Fred H. Elliott, secretary Touring Club of America; Harry Ward, automobile editor Washington *Times,* and J. E. Pennybacker, secretary American Association for Highway Improvement.

The middle route was chosen for the trip to Richmond, via Fairfax, Warrenton, Culpeper, Orange and Louisa. While sixty miles longer than the old telegraph road which goes through Fredericksburg, it is very much superior and more easily traversed. The run to Fairfax was made in an hour, where a two-hour stop was made and speeches indulged in. The party also visited the county clerk's office where the original will of George Washington is on exhibition. The party got away from Fairfax shortly after one o'clock and followed the old Middleburg pike, arriving at Warrenton at 4.30, where a funeral interfered with the meeting which was scheduled at that place. The roads





E—Jonah Run, true to its name, gave the travelers trouble
F—Plowing ditches with a tractor near Bealeton, Va.
G—The road improves as one nears Richmond
H—Vice-President Sherman offers congratulations to the pathfinders

up to Warrenton were fairly good although there were a number of water-bars and much bad going along the old turnpike where the driveway had been made to one side of the road.

After being entertained at Warrenton by members of the Fauquier Club, the party started on the road to White Sulphur Springs, passing the magnificent estate of the late E. H. Harriman. A thunderstorm had preceded the party and the roads were very heavy so that poor progress was made.

As the party was nearing Culpeper on the worst part of the roads yet encountered, a horse belonging to E. Lester Jones became slightly frightened and Mr. Jones turned his horse to one side of the road to allow the car to pass. The horse pranced considerably but made no effort to run away. Notwithstanding this, Mr. Jones telephoned to the sheriff to hold the driver of the car until he could come in. A fine of $25 was imposed for speeding, although all witnesses agreed—including Mr. Jones himself—that it would be impossible to go more than six or eight miles per hour over the road, the speed limit in Virginia being 20 miles on straight roads.

The night was spent at Culpeper and early next morning a start was made via Woodberry Forest School on a fine macadam road into Orange. Here another meeting was called by Commissioner Wilson, and one of the supervisors went with the party to Gordonsville, where they visited a convict camp and watched the process of road construction. The next stop was Louisa where luncheon was served, consisting of Virginia fried chicken with all the attendant delicacies. At three o'clock the journey was resumed, passing through several small villages on the way to Richmond. Twenty miles out the delegation was met by motor enthusiasts of the Southern capital and members of the Richmond Automobile Club who escorted the pathfinding party to the Hotel Jefferson. A representative of the Atlanta Chamber of Commerce met the party at the hotel, having in view the object of securing the convention for Atlanta next year.

The return trip left the Jefferson Wednesday morning at 11 o'clock, stopping at Louisa for luncheon. The route was retraced as far as Orange, but beyond Orange, instead of going through the grounds of the Woodberry High School, the regular road was followed which had but one turn and over which better time could be made, especially where there are a large number of cars, as the road through the school grounds is very narrow and winding. Culpeper was reached about 6 o'clock and the town was found to be overrun by soldiers of the State militia who were encamped just outside the village.

From Culpeper it was decided to follow the Southern Railroad to Remington. On this stretch about seven miles of macadam was encountered, the only untoward incident being the fording of Jonah Run which was greatly swollen by heavy rains on the night before so that water came up into the carbureter and stopped the pilot car. It was necessary for the occupants to remove their nether garments and push the car out to a point where the carbureter could be drained and again put in action. At Bealeton a road runs directly to Warrenton which is undoubtedly the best way to make the trip and the way which the cars will be routed in October.

However, having in view the exploration of the shorter route the cars proceeded along the route to Calverton, Catlet, Nokesville and Bristol to Manassas, where a number of Union and Confederate veterans were hobnobbing together in commemoration of the fiftieth anniversary of the memorable battle of Bull Run.

From Fairfax the cars went over a new piece of macadam to Vienna and thence into Falls Church, across aqueduct bridge into Washington, which was reached at 4.10 p. m. Thursday.

Reflections of the French Grand Prix

The latest news to hand from France has it that mechanical troubles put more drivers out of the running than did the tires, as was first thought. The heat was terrific for cars to run the mileage required and no doubt this was responsible in a certain measure for part of the troubles.

ALL credit is due to Hemery on the Fiat for his victory in the French Grand Prix, as the car was a stock car, from external appearances, and in an interview after the race Hemery stated that he and his mechanic had to stop quite frequently to reverse the spring shackles, which were designed to receive the weight of a touring body to hold them down. The outstanding feature of the day was the consistent running of the small Bugatti rated a 7 horsepower with a Monobloc motor of 2 1-2 by 4.3 bore and stroke. The small car held on tenaciously to the last and was only prevented from finishing owing to the fact that the roads were thrown open to traffic at 4 o'clock, there being two other cars still in the running, a Rolland Pilain and a Cote.

The following is the list of cars that were put out of the race and the cause of the trouble: Porthos, cracked cylinder; Cottin, broken steering gear; Rolland Pilain, broken front axle; Corre (Fournier), broken front axle; Cote, broken change speed lever; Cote broken radiator; Excelsior, spark plugs stuck in steel cap; Rolland Pillain, broken front axle; De Dietrich, broken differential; Gabriel, magneto trouble.

The illustrations show the method of banking the turns so that a driver will have a chance of keeping on the road even if he were to take the turn wide. The car driven by Fournier was four years old, while the Deitrich, driven by Duray, has stood the racket for five years.

In all fourteen cars faced the starter, and when it is remembered that only four were running at the finish, and most of the others had been put out by mechanical troubles, it is an object lesson that manufacturers had better stand down rather than run cars that have not been tested.

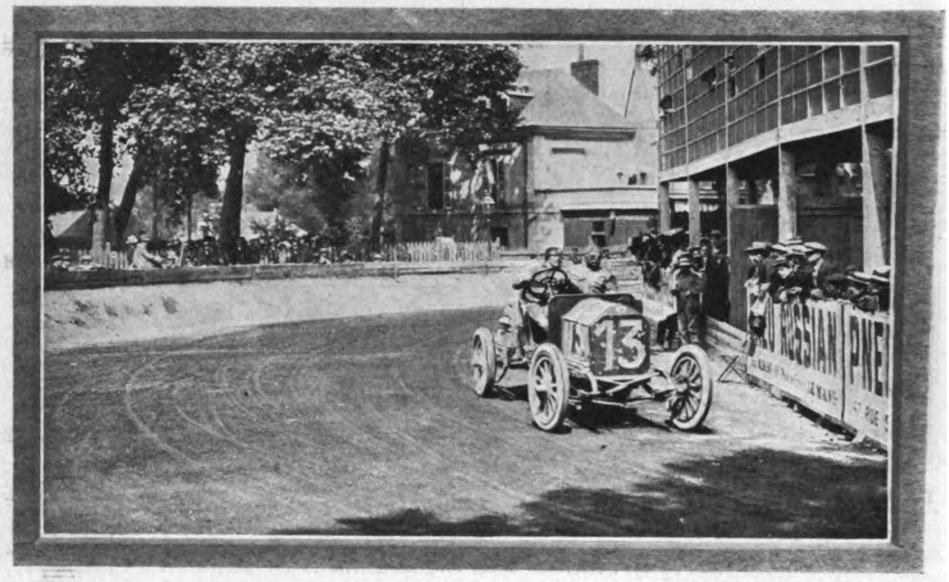


Fig. 1—Hemery in Fiat rounding the turn at the grand stand. The outside banking will be noticed

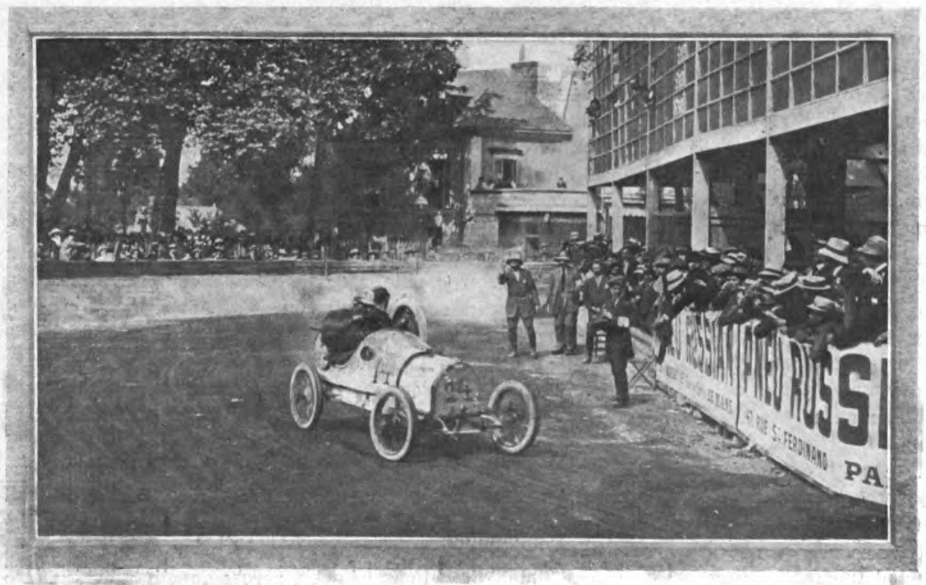

Fig. 2—The 7-horsepower Bugatti receiving the plaudits of the spectators for the fine performance it put up

Protests Winner of Wisconsin Tour

MILWAUKEE, WIS., July 31—The protest of the Jonas Automobile Company, Milwaukee, against the awarding of the *Sentinel* and the *Evening Wisconsin* trophies in the second annual Wisconsin reliability tour to any car but No. 1 Cadillac, has been denied by Referee Michael S. Sheridan on the ground that the protest was entered after the expiration of the 24-hour limit after the posting of the official score at the headquarters. The Jonas company has now appealed to the contest committee.

The official score gives the *Sentinel* cup, a sweepstakes, to the Imperial No. 8 and the *Evening Wisconsin* cup, for best score in the roadster class, to the Ford No. 6. The Imperial also wins the *Journal* cup for touring cars.

The protest was based on the allegation that the first examination of the Cadillac returned this car with a perfect score, giving it first place in the entire tour. It seems that the technical committee of the W. S. A. A. examined the Cadillac, No. 1, and after completing work on this car released it from the official garage, which was the Auditorium. Immediately other contestants demanded that a Contest Board man be present at the examination and the Cadillac was called back and re-examined when F. E. Edwards arrived in Milwaukee.

The Jonas company claims the Cadillac was marked perfect at the first examination and that the three points imposed when Mr. Edwards arrived might have been due to damage sustained by the car while out of the official garage. In addition the company claims the committee had no right to release the car and then recall it.

Premier Fleet on Last Stage

RENO, NEV., July 31—Still ten cars strong, the flotilla of Premier automobiles owned and driven by amateurs on a pleasure jaunt across the continent from Atlantic City, N. J., to San Francisco and Los Angeles, is on the home stretch. The party will essay the climb of the Sierra Nevada mountains, probably in the vicinity of Truckee, the intention being to proceed to San Francisco by the northern route.

Diller, Neb., Helps Form Club

OMAHA, July 31—The southern counties in Nebraska are especially interested in good roads and in automobile clubs. D. E. Watkins, secretary of the Nebraska Automobile Club, made a tour through these counties, last week, organizing automobile clubs. The little town of Diller, whose five hundred inhabitants have stirred up such an interest in good roads in southern Nabraska, still has the same keen spirit. A meeting was held at Fairbury, Monday night, and fifteen automobiles drove the fifteen miles to Fairbury from Diller. There was a large attendance at the meeting, and the club was formed with fifty-one charter members. The following officers were elected: J. W. McDonnell, Fairbury, president; L. M. Nelson, Fairbury, vice-president; W. M. Lewis, Fairbury, secretary and treasurer. A director was elected from each township in the county to oversee the roads of that township.

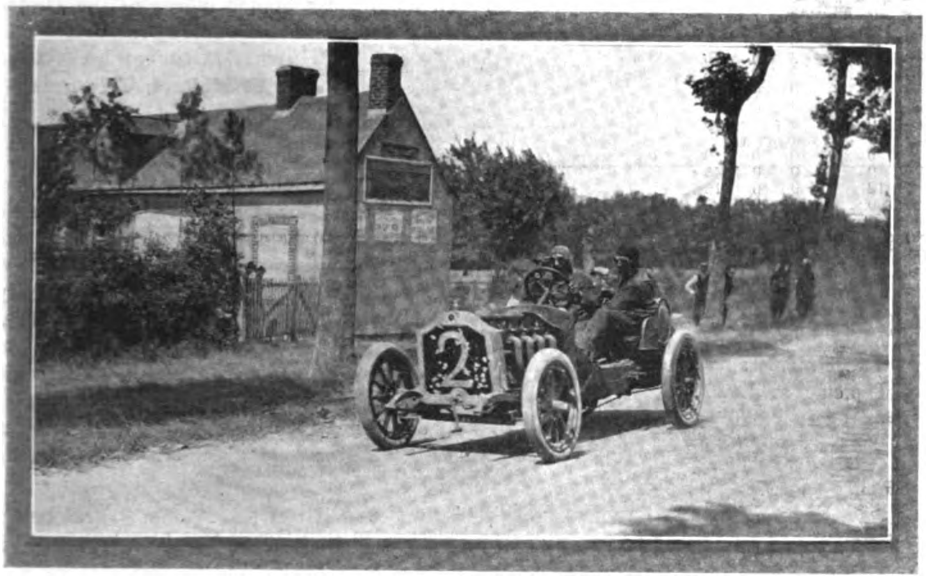

Fig. 3—Maurice Fournier, snapped a few minutes before his fatal accident, due to the breaking of the front axle

Syracuse Club Host to Orphans

SYRACUSE, N. Y., July 31—One hundred and seventy-eight of the children of The Onondaga Orphans' Home were guests of the Automobile Club of Syracuse, Thursday of last week, on a motor car ride about the city and to the Onondaga Indian Reservation, concluding with an outing on the farm of Edward I. Rice, at Dorwin Springs.

Fifty cars were loaned by members of the club, and there were several cars sent in excess of the demand.

All but a dozen children enjoyed the outing. These youngsters, who were suffering from whooping cough, were promised a joy ride of their own as soon as they shall have recovered.

Barnes to Sell Steel Castings

Claire L. Barnes & Company has completed arrangements whereby it becomes direct factory representative, selling the entire output of the Fort Pitt Steel Casting Co., McKeesport, Pa., makers of small steel castings exclusively, from a direct steel process.

Minnesota Winners: Marmon; Flanders

With clean road scores after a grueling drive across the mountains to Helena, the Marmon touring car and two Flanders runabouts were awarded the honors in the registered classes in the annual tour of the Minnesota State A. A. All the contestants in the unregistered division were given clean scores. The affair proved to be an unqualified success.

HELENA, MONT., July 29—According to the announcement of Referee Dutton to-day, the Marmon driven by B. Fawkes, and two of the three Flanders, Nos. 12 and 14, were clean in the regular competition in the Minneapolis-Helena automobile run that has ended here, after a tour of nine days.

The Minneapolis *Journal* trophy was awarded to the Marmon in the Touring car class, while No. 12 Flanders was given the Phillips trophy in the runabout class, with the Gregg trophy going to the No. 14 Flanders as second prize. The Colby, which had 5 points against it, was given the Warner trophy as second prize in the touring car class.

It still is undecided which of the four cars will get the special Minnesota State Automobile Association trophy which was put up for competition among the cars which had not been registered as stock with the Contest Board. All four of these—a Pierce-Arrow, a Packard and two Kisselkars—are eligible, for each had a perfect score.

The contest was run under grade 3 of the A. A. A. rules, penalizations being only for work and time and with no technical examinations at the end of the run. Had there been one it almost is certain none of the cars that participated would have been perfect.

The tour was unique in that it was accompanied by a special train on the Great Northern Railroad, furnished by President Louis Hill, which was used by the tourists for a hotel, meals being eaten aboard by the motor travelers. Another feature of the run was the good roads angle. A prize, the Hill trophy, was offered the Montana county having the best roads. By vote of contestants this was given to Lewis and Clark county.

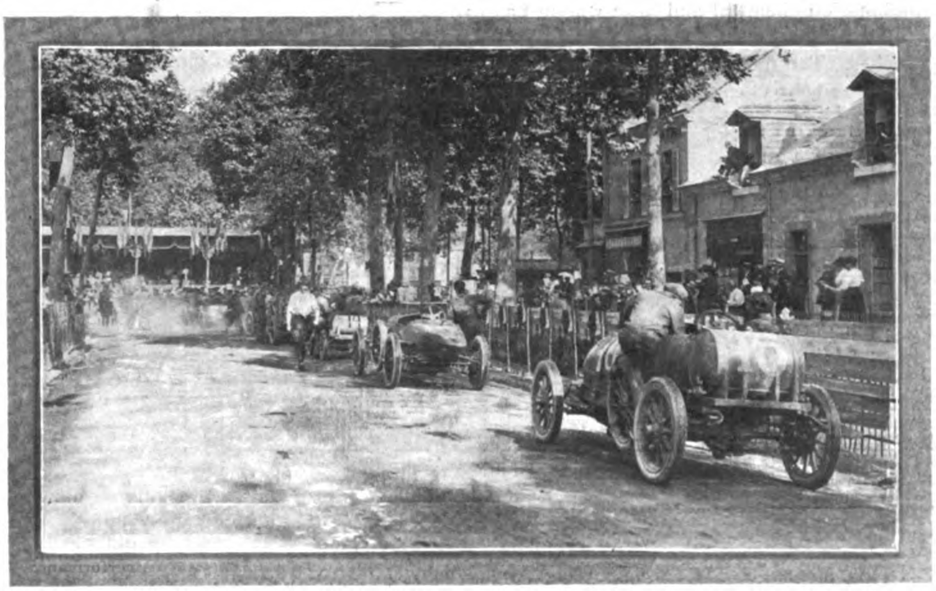

Fig. 4—General view at the start, incidentally showing one of the bad turns and the handful of spectators

Four of the cars in the tour, accompanied by one from Helena, continued from here to Glacier National Park, 250 miles farther in the heart of the Rockies, as guests of Louis Hill, president of the Great Northern. A run will be made by motor to Kalispell, a 2-day trip, then follows a 3-day journey on horses through the park. The cars in this trip are the Brictson Pierce-Arrow, which acted as press car on the tour; C. P. Merwin's Corbin, the pacemaker; Louis Hill's Packard and Walter Berkey's Packard. The party is accompanied by the special train. The summary:

No.	Car and driver.	1st day	2nd day	3rd day	4th day	5th day	6th day	7th day	8th day	9th day	Total

Franklin Workers Enjoy Picnic

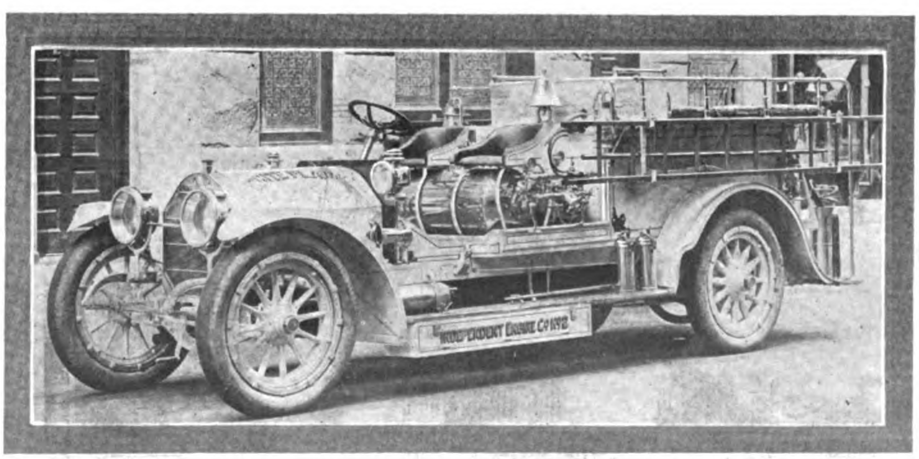
SYRACUSE, N. Y. July 31—The employees of The H. H. Franklin Manufacturing Company held their anuual picnic at Long Branch to-day, 4,000 persons being present. The resort is a few miles from Syracuse and reached by trolley. A feature was a concert given by a band of twenty pieces. There were various athletic events. It was the largest-attended picnic the Franklin forces have ever held.

Locomobile Fire Wagon for White Plains

While the tendency to displace horse-drawn fire apparatus by motor-driven vehicles is very pronounced in the large cities of the land it is even stronger in the suburban localities and in the smaller cities.

The following towns near New York have contracted for motor fire apparatus, some of which is being delivered now and some of which has been installed: Passaic, Paterson, Newark, Bronxville, Irvington and White Plains. In the latter place a Locomobile combination chemical and hose wagon has just been delivered.

The new wagon is rated as 40-horsepower, four cylinders, 5 by 6 inches. Ten men can ride on it and there is room for 1,000 feet of hose and two chemical tanks with ladders and other equipment.



Locomobile combination fire wagon in service at White Plains, which was recently delivered to that town

U. M. Parts From Component Companies

The dissolution of business relations of the United Manufacturers as a sales organization with four of its chief elements has been officially announced, following a series of conferences, the last of which took place Tuesday, Aug. 1.

The full text of the announcement is as follows:

"The United Manufacturers, as a sales organization, has discontinued the sale of the products of—

"Weed Chain Tire Grip Co., Bridgeport, Conn.

"The Jones Speedometer, New Rochelle, N. Y.

"N. Y. & N. J. Lubricant Co., 165 B'way, New York City.

"C. A. Metzger, Inc., 239 W. 56th Street, New York City.

"The desire to avoid the appearance of a combination in restraint of trade is the purpose of this step.

"The above manufacturers will continue the distribution of their products through the former branch offices of the United Manufacturers, in charge of their branch managers.

"UNITED MANUFACTURERS,
"G. C. Holmes, Treasurer."

Jersey Trade Seeks Open Door

NEWARK, N. J., Aug. 3—The New Jersey Automobile Trade Association, which has hitherto held itself aloof from the wrangles incidental to the administration of the present New Jersey automobile law, has come out squarely against the policy of J. B. R. Smith, Commissioner of Motor Vehicles, and in a series of resolutions, requested him to recede from a position which the association believes is inimical not only to the best interests of automobiling, but of the State of New Jersey at large. The resolutions which were unanimously passed at a meeting of the Trade Association held a few days ago, are as follows:

"Resolved, That in view of the fact that New York State has for all past years since automobiling began (this present year excepted) permitted all residents of New Jersey to enter and use her hundreds of miles of improved roads with the same freedom as her own citizens, provided only that they were duly registered in their own State, notwithstanding that New Jersey has compelled her (New York's) residents to submit to many indignities and to pay a tax; and the further fact that New York stands ready now to grant the free use of her roads to citizens of New Jersey should New Jersey grant her citizens the same privileges, it is the unanimous opinion of the New Jersey Automobile Trade Association that the action of the Commissioner of Motor Vehicles, J. B. R. Smith, in withdrawing from residents of New York the slight privilege which our State law concedes them now, shows a feeling of resentment which one State of the Union should not show to another, and is, in our opinion, very bad judgment; and it is further

"Resolved, That the general principle of serving notice on residents of New York, Pennsylvania and Delaware in effect that they are not welcome to our State is going to do the manufacturing, hotel, real estate and all other business interests of New Jersey untold injury which will take years to make up for, in addition to giving our State a reputation for narrowness of which she is not deserving.

"It is further resolved, That a set of these resolutions be forwarded to Commissioner J. B. R. Smith with the request that he immediately reconsider his action."

The New Jersey Automobile Trade Association, which is composed of the leading dealers of the State, stands committed to the policy set forth, and it is understood, will wage a vigorous campaign for the re-establishment of the eight-day touring privileges to non-resident motorists such as the New Jersey law provides, but which Commissioner Smith has abrogated in the case of certain States.

Heads Croxton Sales Dept.

Geo. S. Patterson, formerly branch manager of the Thomas B. Jefferies Company, and later with The White Company, has been elected general sales manager of the new Croxton Motor Company, of Cleveland, Ohio, and will take full charge of the sales of this company which will manufacture taxicabs, pleasure cars and trucks.

Glidden to Be Good Roads Tour

Owing to the lack of sufficient entries the postponed Glidden tour of 1911 has been abandoned and in its place the tour of 1911 will take place in October and be run over the route of the National Highway, extending from New York to Jacksonville via Atlanta.

Returning to the original idea of the donor of the trophy, the tour, appealing particularly to owners, will be conducted under regulations demanding reliability and regularity, without reference to rigid technical restrictions.

From the Atlanta Chamber of Commerce and the Jacksonville Board of Trade came representatives who were prepared to negotiate a definite proposition. Atlanta was represented by Edwin P. Ansley and Major John S. Cohen. H. B. Race spoke for Jacksonville.

The 1911 Tour will be conducted under Grade IV of the A. A. A. Reliability Rules, with practicable daily running schedules, possible of accomplishment by any tourist.

The cars will be stamped in their essential parts, there will be no observers and the only penalty assessed will be for lateness at controls. A nominal entry fee of $25 will be charged and present indications point to a large entry list of individual owners.

A $200 cash prize will be offered for the best performance in each of the seven price divisions.

Any owner of a stock car shall be eligible to enter.

Entry blanks and full conditions will be issued immediately.

Saurer Truck Reaches New York

Marked with travel stains but otherwise apparently in good shape the transcontinental Saurer truck came to an end of its long journey Wednesday afternoon in New York.

The truck was run down to the City Hall and then up Fifth avenue and came to rest at its garage on Fifty-fifth street. The Motor Truck Club acted as escort for the big car. The car left Denver for New York via San Francisco on March 1 carrying a load of three tons and worked its way across the continental divide and up the Pacific coast. Thence it started eastward and climbed the mountains; forded the rivers and crossed the deserts to the Mississippi valley, completing the last 1,000 miles by easy stages.

Senator Company Ready to Start

PITTSBURGH, July 31—The Senator Motor Car Company, capital $200,000, has completed its organization as follows: President, C. E. Vance, of the Consolidated Manufacturing Company and the Anchor Packing Company, of Philadelphia; treasurer, P. T. Coburn, who was formerly advertising manager of the Westinghouse Electric & Manufacturing Company, of Pittsburgh; secretary and manager, A. F. Schmidt, formerly with the Penn Motor Car Company, of Pittsburgh. The directors are John F. Edmunds, of the Anchor Packing Company, of Philadelphia; Dr. E. R. Walters, head of the Department of Health, of Pittsburgh, and G. C. Campbell, of Pittsburgh.

The company has established offices in the Jenkins Arcade Building on Liberty avenue. It is going to locate on Pennsylvania avenue, North Side, and is fitting up two buildings 80 x 400 and 300 x 400 for its use. It will manufacture four distinct types of cars; a two-seated roadster of 40 horsepower to sell for $1,250 and up; a light delivery truck of 35 horsepower capacity, 1,500 pounds, to sell for $1,000; a heavy delivery truck, capacity three to five tons and of 60 horsepower; a four-seated touring car to sell for $1,800. The roadster will have a 116-inch wheelbase and a 34-inch wheel with 4-inch tires. It will have a straight line drive, low center of gravity, thus distributing the vibration between the axles. A feature of the car will be the straight pulls on the brakes. The company expects to build 1,000 of these roadsters next year.

New "Six" Makes Its Début

MILWAUKEE, July 31—Carl Lipman, president of the Lipman Manufacturing Co., Beloit, Wis., centrifugal pumps, etc., has brought out a six-cylinder touring car built according to his own specifications and for the most part in his own shops. It is highly probable that Mr. Lipman will organize a company to manufacture the car at Beloit. The six cylinders are cast in pairs and a feature of their construction is the fact that the cylinder dome is removable, to permit of ready access to the combustion chamber and the valve mechanism in order to make inspection easy.

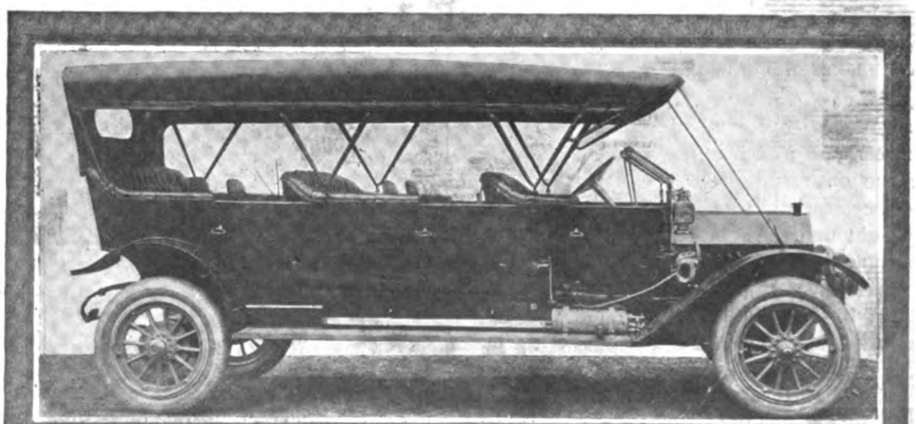
Ignition is by high-tension magneto, cooling by a Lipman centrifugal pump, and the car is supplied with a self-starting device of Mr. Lipman's own invention. The car is fitted with annular bearings throughout. It weighs about 2,400 pounds as put up by Lipman with a toy tonneau, 122-inch wheelbase and 36-inch wheels.

Weed Chain Patent Upheld

CHICAGO, July 27—By decision of the Circuit Court of Appeals in the northern district of Illinois, what is familiarly known as the Parsons patent covering the right to manufacture anti-skid chains for motor car wheels was to-day upheld and the decision of this court made in January, 1911, reversed. The decision was reached by Judges Grosscup, Baker and Kohlsaat, circuit judges, and is the finding in the case of Patent Excelsior or Supply Co. and Motor Appliances Co. vs. Weed Chain Tire Grip Co., Harry D. Weed and Parsons Non-Skid Company, Limited.

General Motors Truck Company

LANSING, MICH., July 31—The General Motors Company, of which the Olds Motor Works is a constituent part, has announced the formation of a selling and service company, under the name of General Motors Truck Company, to market its entire product of commercial cars. The formation of the separate company has been effected to concentrate the efforts of the manufacturing and the selling ends of the business on their respective lines.



Twelve-passenger torpedo recently shipped by Atlas Motor Car Company for summer resort work

Seen in the Show Window

EXTRA seats which fold out of the way when not in use certainly make for comfort, except when they invite some indiscreet acquaintance to force his personality upon the polite owner of the car; but this is only the exception proving the rule, and if the automobilist desires to equip his machine with extra seats, it will be the course of economy to get high-class goods, even though they may be a little high priced. Quality is the principal claim made for the patent Luxury folding seats (BI), the framework of which is made of drop-forged steel, making possible a rugged and compact construction, while artistic design and finish furnish the good looks. These seats are the product of the Graves & Congdon Company, Amesbury, Mass.

REMEMBERING that the cooling water as it flows from the radiator to the engine cylinder jackets is moved through the office of a pump, and that this latter puts the water under pressure, it is easily understood that all water hose must be absolutely waterproof, and connections very tight lest some water be lost. This would not only result in the water being spilled all over the power plant, but the motor not being cooled to a sufficient measure would be damaged by the process. To avoid leaky connections hose is generally pressed against a pipe with some wire, but besides the fact that this is not a reliable method, the hose will suffer and in time will be cut by the wire. A pump connection using a similar principle in a refined sort of way is seen at (BJ), it being the Nielsen's. It is attached by pulling back the ring pressed by a spring against its seat which is cut into six sections. Thereafter the end of the hose is slipped over these sections and held in place and the ring pushed into place by the pressure of the spring. The Auto Equipment Manufacturing Company, of 18 Pearl street, Newton, Mass., market this device.

STORAGE batteries, so widely used for lighting automobiles and igniting the gasoline-air mixture, differ principally on account of the method of how the active material is placed in the plates, a good construction resulting in an increase of efficiency rather than one of capacity per weight unit. At the same time, a high efficiency is indicative of a relatively long battery life, proving that one virtue is always in another virtue's company. The illustration (BK) shows the Bison Sparker, a battery comprising three six-volt cells which will last through 40 ampere-hours, and the advantages mentioned above are claimed to be present in this make of battery. At all events, the illustration gives an idea of the compact and strong construction of the battery which is made by the Bison Storage Battery Company, of 38 Riley street, Buffalo, N. Y.

MEASUREMENTS are now made compact and precise, owing to the vast experience of the manufacturers of the meters and instruments used for the purpose, and while the first of these products necessarily had to be of medium size, since it then was not possible to combine the features of miniature and precision, capable instruments are now manufactured, these being of sufficiently small size to be carried in one's vest pocket. In Fig. (BL) we illustrate the Read-Rite, which is a volt-ammeter and made by the Read-Rite Meter Works at 18 Main street, Buffalo, N. Y. The plug connecting the meter with the electric line to be tested can be taken out of its socket and kept separately.

ELECTRIC accumulators cannot be charged directly from a high-tension main since too high a voltage would do damage to the cells. It is for this reason that some kind of resistance must be used and placed in the circuit to reduce the voltage, and of these resistances, lamps are the most popular, though not the handiest. A small and effective resistance is the battery-charging rheostat illustrated at (BM) containing no wires or grid which might be burned out by the process of charging, and it may be mounted either on a wall or switchboard. The working parts being well insulated are not affected by moisture which therefore does not disturb the successful operation of the rheostat. It is sold by Howard M. Eldred, of 818 Pabst Building, Milwaukee, Wis.

EVERY automobilist will admit that he likes to have the time before him when driving, but not every one will indulge in the expense of buying a specially constructed timepiece to be permanently attached to the car. Automobile operators will be interested in the realization of a very practical scheme by which it is possible to attach one's watch instantly and safely to the steering wheel of the car, without fear that it will be thrown off by the movements of the machine. The winding post of the watch slips into the notch of the time clutch (BN), and the whole thing is supported by the two bent-up pieces of metal. The clutch is screwed on to a nave of the steering wheel; it is furnished in nickel, polished brass or gun metal finish by its makers, the Sterling Manufacturing Company, Inc., Staunton, Va.

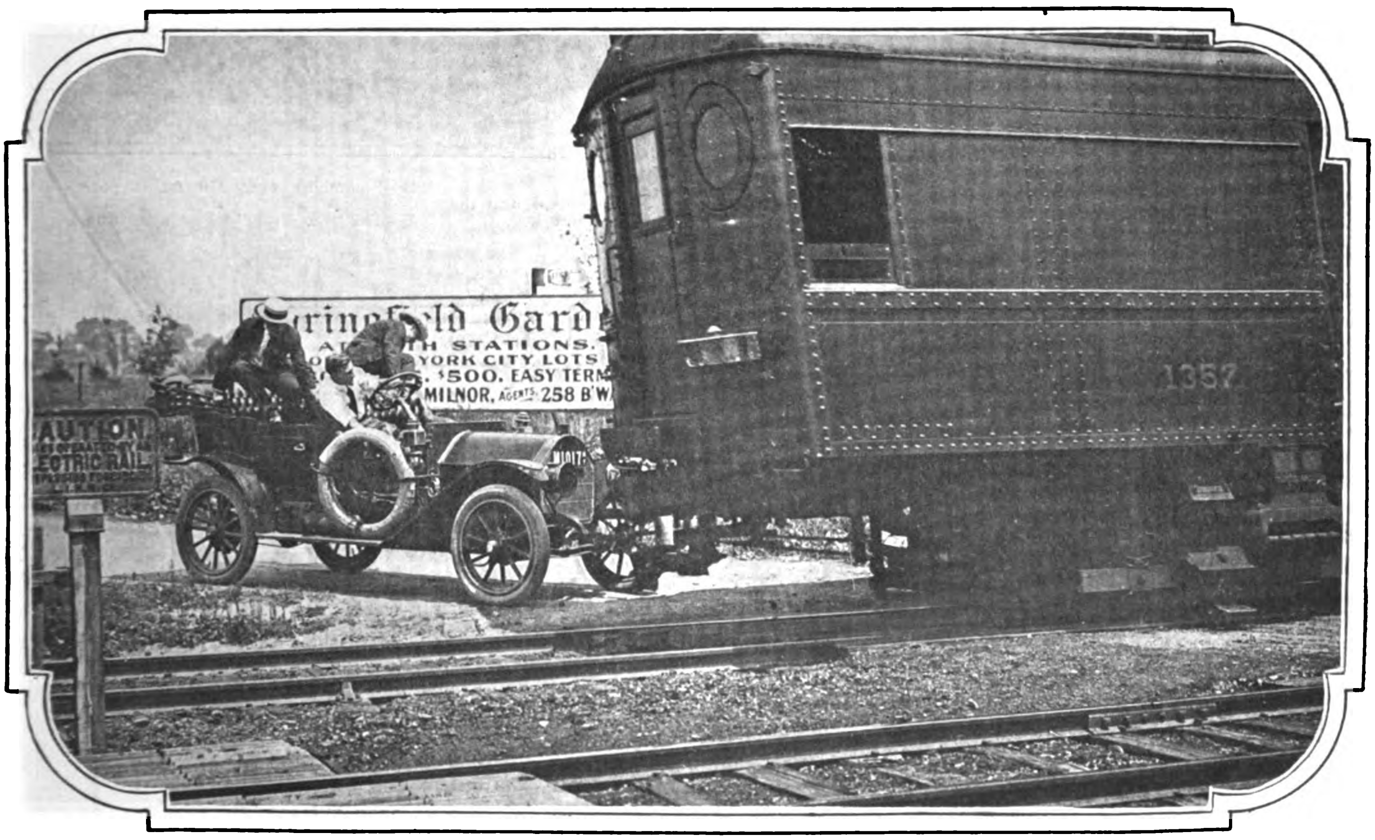
VOL. XXV NEW YORK—THURSDAY, AUGUST 10, 1911—CHICAGO No. 6

THE AUTOMOBILE

Grade Crossings a Prime Nuisance

Take 87 Lives in About Ten Weeks' Time

Besides being uneconomic from the viewpoint of railroad operation, grade crossings have proved themselves to be a fearsome danger to all kinds of traffic, particularly automobiling. The daily press recounts a fatality or more nearly every day, all of which are sinfully unnecessary. By delaying traffic the grade crossings take something from the pleasure of riding in an automobile or carriage, and consequently put a damper on realty values in the sections affected.

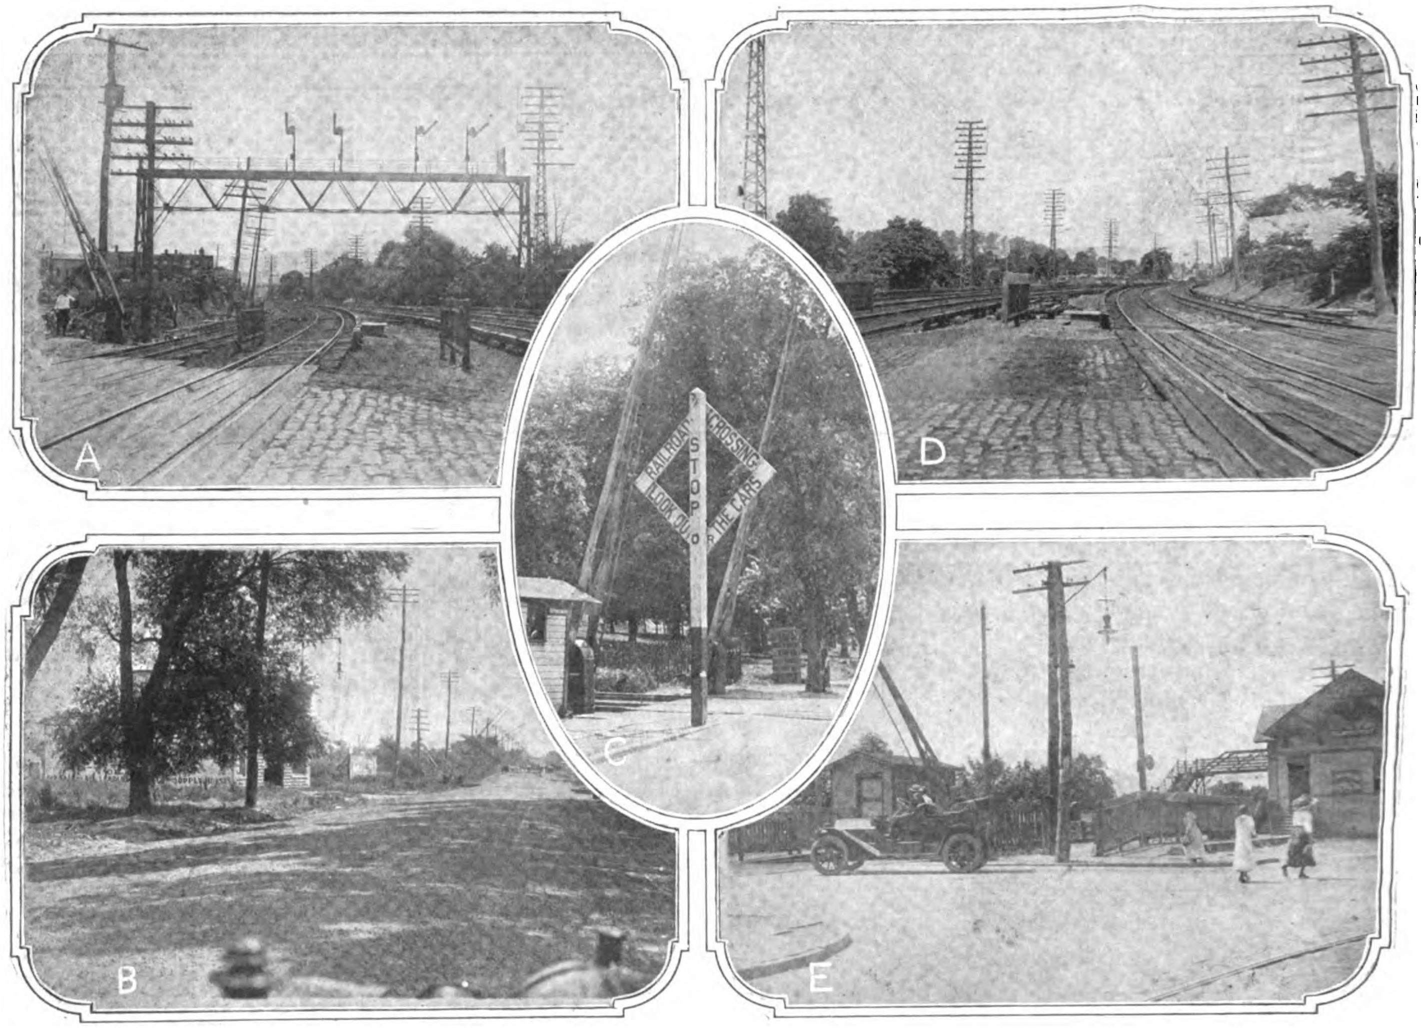


"THE UNDERTAKER," A CROSSING NEAR SPRINGFIELD UNPROTECTED BY GATES

SINCE the middle of last May there have been twenty-two legal executions in capital cases in the United States. As all the persons killed by the law were previously convicted and presumably deserved their fate, there was only the usual amount of criticism for the system of punishment that makes legal killings a part of society's machinery. But during the same period there were eighty-seven persons riding in automobiles and carriages who were slaughtered by railway trains at grade crossings. They were not criminals and presumably, at least, did not deserve their fate and yet, nevertheless, they are just as dead as the murderers who were hanged or shocked to death.

As a matter of fact, the victims of the grade crossings were very largely persons of culture, refinement and wealth, and to a notable degree represented the best elements in society. They met death in New York, Pennsylvania, New Jersey and a dozen other States. The destroyer sprang at them without warning and crushed and mangled them without mercy. Too late to be of service, the safety devices of the locomotives shrieked their futile warnings and the wailing whistles and grinding snarl of the brakes proved only to be a horrible death knell for the victims.

Since May 15 last eighty-seven persons have been sacrificed on



A—Upper curve leading to "Yawning Death" crossing Thompson avenue, Winfield
B—The "Silent Tomb" crossing of Thompson avenue

C—Showing poor placing of warning sign at the "Rat Trap" in Elmhurst

D—Something over 350 trains pass this point daily
E—The "Rat Trap," where a backing train might cause disaster

the useless altar of the grade crossing. Some were bankers, some lawyers, some business men, some society women, some gentle mothers and some innocent children. Death on the grade crossing plays no favorites and respects no rules, and instead of being useful members of their various communities the victims are now reduced to the ultimate clay.

The grade crossing is an anachronism. It belongs to another time. It never was anything but a peril that was countenanced in the past so that the progress of swift transit might be furthered. To-day there is as little excuse for it as there will be for cavalry in the next great military campaign.

Not one word can be said in favor of retaining a single crossing at grade of any traveled highway in the United States by any railroad. Such crossings add to the cost of operating the railroad property. They make necessary the employment of a host of inferior labor on a job that requires supreme judgment, or in its absence, cataclysm.

With no grade crossings, the railroads could make better time at less expense and if there had been no grade crossings in the United States on May 15 eighty-seven men, women and children now resting under the sod would still be living.

The history of the grade crossing is the history of the railroad up to about the beginning of this century. Prior to that time there had been many improvements urged and agitated, but little of real accomplishment had been done in the line of eliminating them except in the centers of densest population. Even at such points there were numerous crossings that came to be known as death traps, slaughter house curve, the graveyard and by other sinister names. Public opinion has forced the elimination of many of these, but even to-day there are literally hundreds of such crossings still in existence in the largest cities, and some of the eighty-seven lives that have paid the penalty since May 15 were lost upon them.

To the credit of the railroads it may be stated that in the big towns, at least, a determined effort has been made to safeguard the lives of citizens. Gates and gatemen have been established and where the crossing is approached by a curve from either side, signalmen in a few instances have been provided. Warning signals have been installed in many dangerous places and signs telling of danger are to be met with frequently.

All these things have been done and still eighty-seven lives have been taken from passengers in automobiles and carriages in a little more than ten weeks.

There are two factors in the present system of "protection" of grade crossings. First the mechanical and automatic warnings and guards and second the human agencies that work with the machines and independent of them. Of the first it may be said that they work splendidly as long as nothing is the matter with them, but they are subject to accident and frailty and natural wear and tear and in addition they sometimes fail to work at all without any known cause.

As far as the flagmen and gatemen are concerned, they are only men after all and are neither immortal, infallible or invulnerable. When a brakeman loses a leg in the line of duty he is automatically placed on the eligible list for gateman at a grade crossing. When an engineer is crushed out of shape and disabled he is sometimes made watchman at a crossing. Frequently the veterans who have served long and honorably in the operating departments of railroads, but who have been so unfortunate as to outlive their usefulness in those capacities, are pensioned off by being allowed to guard the lives of men, women and children at some dangerous grade crossing.

Old age is no crime, neither can a man be blamed for accepting employment after being disabled for his regular work, but the question stands out sharply: Why are such men used to guard the most precious thing in the world—human life?

Let us suppose a case something like this: A grade crossing of six railroad tracks traversing a main traveled artery of commerce. Suppose that this crossing is approached on a curve that prevents drivers of automobiles or carriages from seeing for themselves that the way is clear or the contrary. If there is a flagman stationed on the curve to warn the gateman of the approach of a train, in addition to the other safeguards of an automatic nature, the chances are that thousands of signals may be given with exactness by one or both of the systems, but eventually, a puff of wind will extinguish a lantern, a drop of rain or a pellet of hail striking a man in the eye will put him out of commission for a moment and if at that instant a train is whirling down upon the crossing and if the insulation of the safety signal device should happen to be worn, or the wire grounded in the wrong loop, or any of a thousand different mishaps should intervene, then death looms large for those using the crossing.

The element of frailty in the personal equation cannot be overlooked and just as long as there are grade crossings guarded by frail human beings, just so long will there be terrifying slaughter resulting from the perversity of human nature.

There is nothing that seems to be quite so useless as to try to improve the protection of grade crossings. Whenever a great effort is made to protect a certain crossing, like the one on Thompson avenue at Winfield, it means that the danger of slaughter at that particular point is tremendous. There is no doubt that it is protected as thoroughly as any in New York City and yet it is reasonably called "Yawning Death" and numbers its dead by the score and its cripples by the hundreds.

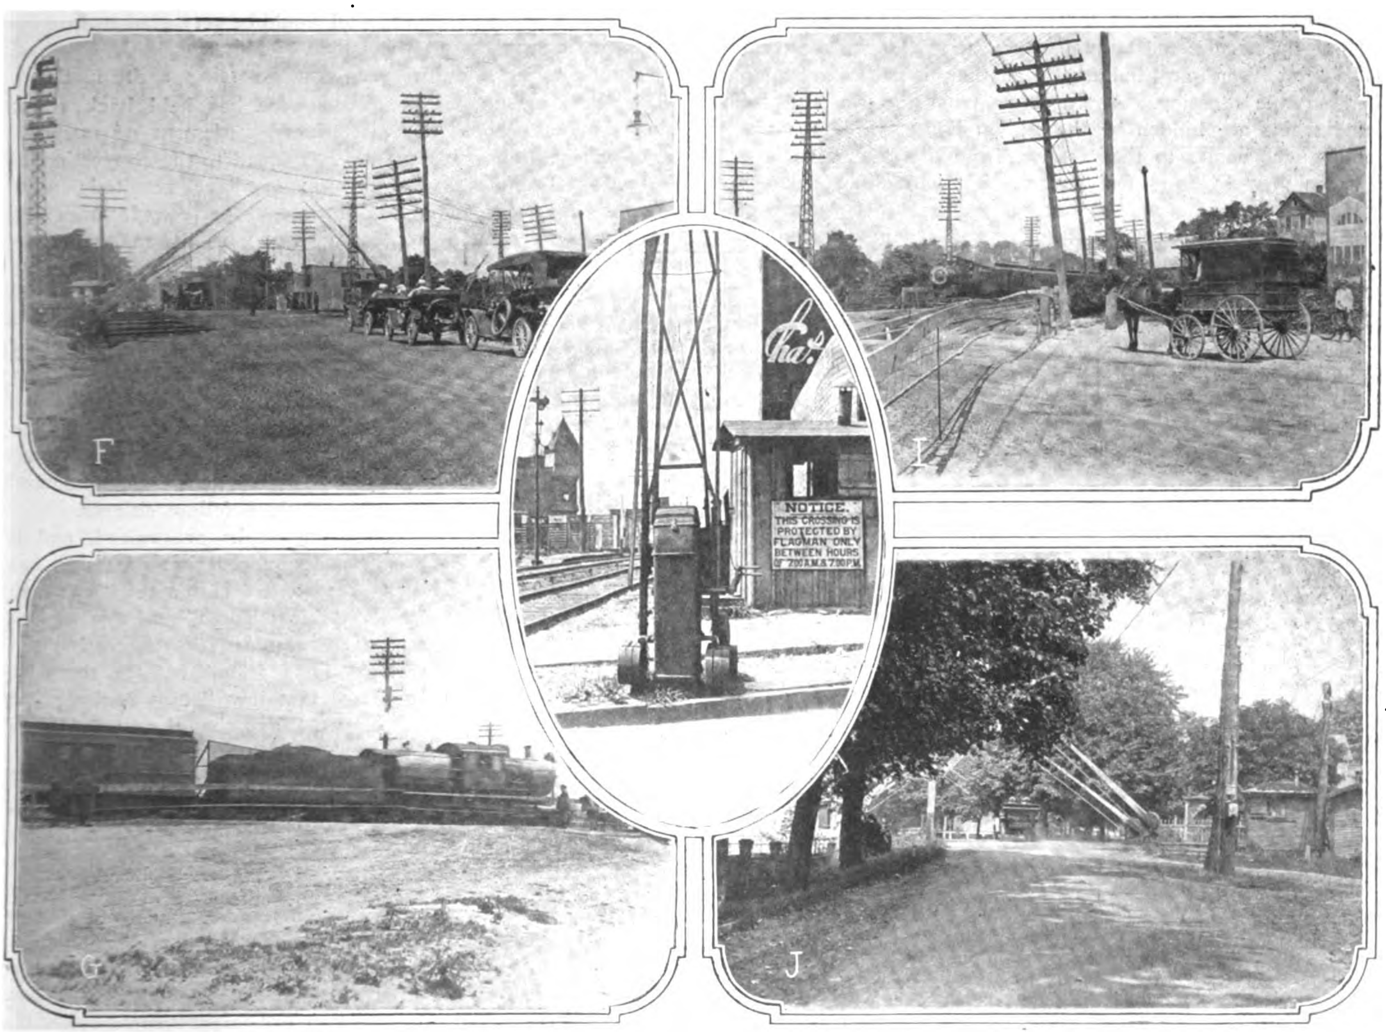
All present efforts to protect grade crossings are futile and as they represent the height of human care and ingenuity, it would seem as if nothing further could be done in that line. It would appear that any additional effort to perfect the system of protecting grade crossings is quite as unreasonable from every human aspect as would be the abandonment of existing and prospective subways and rapid transit and the extension of the present horse-drawn surface cars in New York City.

The answer to the problem is to eliminate the crossings, root and branch.

Such procedure is expensive in first cost, but on the part of the railways it must prove economical. Vastly better time will be possible. Vastly less expense will be attached to such operation. But even if it should prove to be a dead loss to the railroads, it would be far better to have the grades eliminated than that the present tremendous death toll should be exacted for even one year more.

The Central Railroad of New Jersey ran down and crushed an estimable party the other day and the Pennsylvania chopped a big touring car to bits and killed four prominent persons near Pittsburg last week, and the daily press recounts a tragedy of the grade crossing somewhere nearly every day, sometimes half a dozen of them.

Consequently, the special attention paid to the crossings of the Long Island Railroad are not intended as a special criticism of



F—Automobiles and other traffic have to wait on passing trains
G—One danger is where a slow and a fast train travel in the same direction

H—"The Hospital," a grewsomely named crossing on Eastern Boulevard

I—With the gates down at the Thompson Avenue grade crossing
J—"Gates Ajar," a tree-lined grade crossing that has a record

that particular railroad company. In fact, they are probably well up to the average in the matter of safety. The accompanying illustrations, photographed recently at several of the Long Island grade crossings, were taken by the staff photographer of THE AUTOMOBILE, mostly from a Velie touring car furnished for the occasion by the Garland Automobile Company.

The main traveled highway leading from the Queensboro Bridge to the interior of Long Island is Thompson avenue. It is the most convenient route to the north, center and south of the island, and at such events as the Vanderbilt Cup race or other big national functions staged near Garden City it is thronged with thousands on thousands of automobiles. Only a short distance out the road crosses the main line of the Long Island railway and the place is known locally as "Yawning Death." There are four tracks, two east and two west bound, separated by about 20 feet of roadway paved with cobblestones. There are gates, gatemen, signal bells, flagmen up the track on each side at the curves and yet its death list is appalling.

Entirely aside from the fact that it is one of the most popular haunts of The Reaper, the crossing is an unmitigated nuisance. Half the automobile commuters living on Long Island are obliged to pass "Yawning Death" at least twice each day and as something over 350 trains shoot over this crossing every weekday, the delays occasioned by shut gates have proved a deterring influence to the general use of the automobile.

Many a man would own a car and use it in commuting if there was no such thing as "Yawning Death" to spoil his temper, make him late for dinner or perchance snuff out his life.

A little further along is another crossing known as the "Silent Tomb." This also has a bloody history, being particularly treacherous at night. "Silent Tomb" is protected by gates, but west bound trains are concealed from view by the beautiful trees that line the avenue and buildings that stand close to the tracks.

The "Rat Trap" at Elmhurst is another magnificent example of the grade crossing. Approaching from the west, all east bound trains are hidden by the station house, while the automobilist who comes to the crossing from the other side is cut off from view by trees and houses. The chief danger at this crossing in daytime would develop if from some untoward circumstance the gates should not be lowered when the train happened to be backing across the street. At the time the representatives of THE AUTOMOBILE visited the "Rat Trap" a train did back down across the street, but the gateman lowered the barrier in plenty of time.

The "Hospital," as the crossing on Eastern Boulevard is called locally, is as dangerous a grade crossing as there is in New York. The tracks shoot out from behind the buildings and, according to the posted warning, gates are not in commission from 7 o'clock in the morning until 7 o'clock at night. Mothers in the vicinity are accustomed to warn their children in starting out to school: "Now be careful or 'The Hospital' will get you." The record of "The Hospital" is not bloodless.

"Gates Ajar" is the name of another crossing near Elmhurst. The name probably does not refer to the fact that the protective gates are raised when no trains are in sight. The residents of the vicinity in all likelihood imposed the name from some similarity they found between the crossing and the well-known and appropriate funeral floral piece.

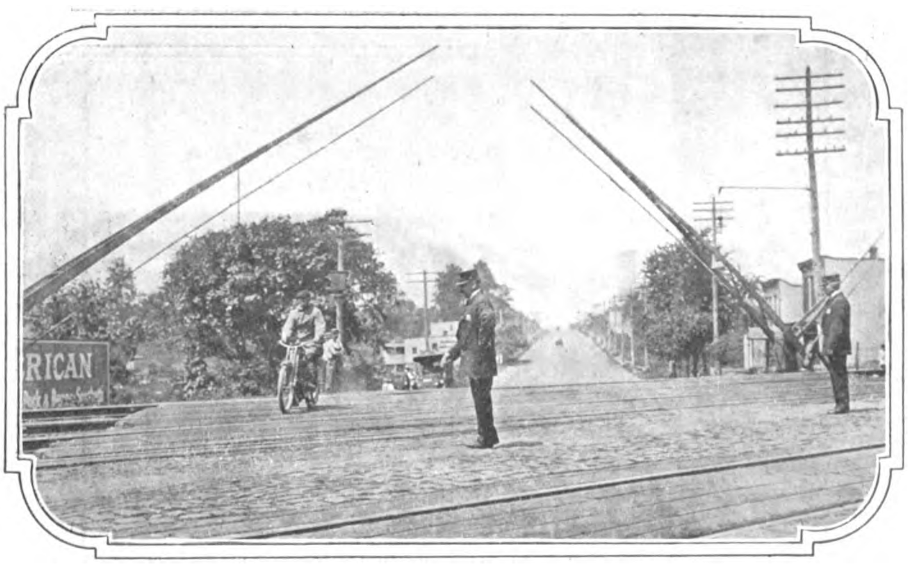
But the most dangerous of the lot is the crossing of Palmer avenue, near Springfield, by the beach branch of the railroad. This road is now the most heavily traveled by commuters and tourists, owing to the fact that the regular route over the Merrick road is undergoing radical repairs.

At the point shown in the accompanying photogaph and which is called "The Undertaker," there are no gates, or at least there were none the day the inspection was made. "The Undertaker" enjoys a few advantages, despite the danger that resides in lack of gate protection. The tracks are visible for quite a distance to the north and are only concealed from view to the automobilists approaching from the east. The motive power used on this branch is mostly electricity and the silent trains give absolutely no warning.

The six crossings, "Yawning Death," the "Silent Tomb," the "Rat Trap," the "Hospital," "Gates Ajar" and "The Undertaker," all have known records. In fact, the residents of the district presided over by "Yawning Death" state with all sorts of emphasis that the slaughter officially charged against that crossing is only a small part of the actual total casualties. But when all has been said, these crossings are only typical of grade crossings everywhere. The railroad would be very glad to lose the whole six overnight and the public would be equally relieved. The same may be said for every grade crossing in the land.

The fact that the crossings do exist has held back realty values in Queensboro; has discouraged settlement of many of the open places and consequently has added to the congestion of Manhattan Island. Numerous killings have resulted; more numerous injurings and destruction of property and under this head must be reckoned the loss of revenue to the railroad company by reason of slow operation as well as the actual loss represented by additional operating expenses. But besides all these things, anything that tends to make the use of the automobile perilous or that which detracts from the pleasure and benefit of automobile operation, reacts as a deterrent influence upon the automobile business.

In this way the makers of automobiles are interested in the grade crossing problem, quite aside from their natural human instincts of horror at the slaughter and maiming of their fellow citizens.



Looking west from Winfield crossing

When the tracks are raised, and it has been announced that provision has been made to eliminate "Yawning Death," "Silent Tomb" and one or two others, the greatest obstacle to the welfare of Long Island will be removed. It is said that it will cost $2,500,000 to do this work and that the city will pay $600,000 as its part.

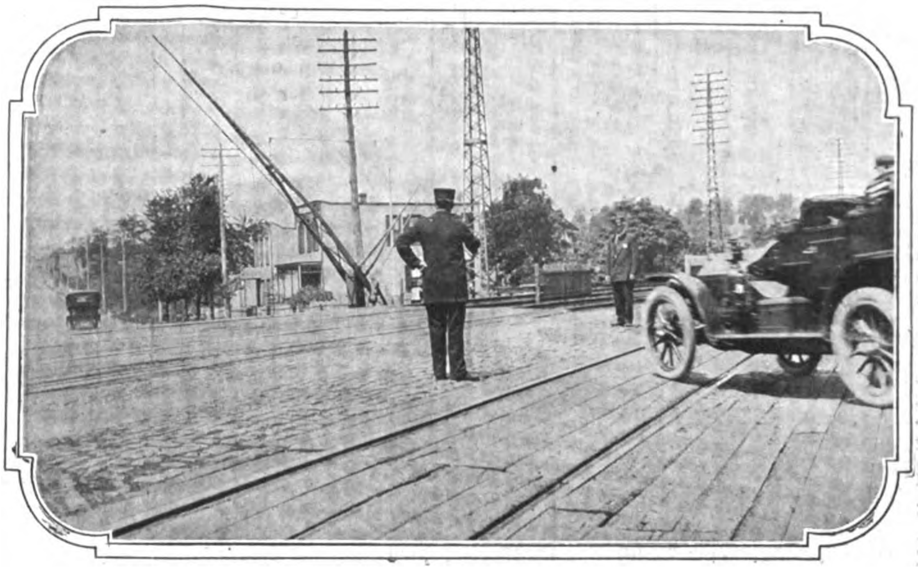
The legal price of a human life used to be $5,000, but it has been raised somewhat lately. Supposing that only ten lives a year, appraised at $10,000 each, are saved by this expenditure, the amount of saving would be $100,000 or 4 per cent. upon the investment. This is at least savings' bank interest on the bonds that would be issued and in addition to that rather comfortable sum the railroad would be adding materially to its gross earnings from operation and decreasing its operative costs by reason of the better condition of its right-of-way. Neither of these items takes into consideration the saving to individuals in property, automobiles, carriages, baby-buggies, etc., that will not be destroyed on the grade crossings.

Thus, besides being dangerous, the grade crossings are uneconomic and their purpose would be better served by elevating the traffic of the railroads and depressing the surface of the streets, or the contrary as the circumstances of the particular case may warrant.

President Peters of the Long Island Railroad was quoted as saying immediately after a recent multiple killing at Winfield that the railroad could do nothing more and that the only solution of the problem was to eliminate the grade crossings.

He knows as well as any railroad man that the limit of human effort has been made to protect life at this crossing, and when he says that nothing further can be done it simply means that the crossings must be eliminated as quickly as possible.

Carelessness might account for a few of these accidents, recklessness on the part of drivers has been blamed for some, but deep down and beyond there is the crossing itself—sufficient unto itself to account for the bulk of the slaughter.



Scene of recent fatal accident

Items from Foreign Lands

What the English are doing in the matters of the testing of road materials, Sunday opening of automobile supply stations, keeping learners off the busier roads, etc.—Statistics show a decrease of horses in the French capital.

IMPORTANT tests of twenty-three different kinds of road materials are being carried out jointly by Kent County Council and the Road Board on the main London and Maidstone road, between New Eltham and Sidcup. Trial lengths are being laid with various materials, the work is conducted under the supervision of the Advisory Engineering Commission of the Road Board.

English automobilists are making strenuous efforts to influence the Government to insert a clause in the proposed Shops Bill (the Parliamentary Act to regulate Sunday openings) which will permit dealers in automobiles and motorcycle accessories to sell parts, gasoline, lubricants and so forth to motorists who travel on Sunday.

The secretary of the North-Eastern Automobile Association (England) has addressed a letter to the press with regard to learners of motor car driving on the public highways. The association also extended copies of the letter to garage proprietors and motor-car agents in the North of England, requesting them to discountenance as far as possible the giving of lessons to learners on busy roads. It points out that danger can practically be eliminated if care is exercised in the selection of straight and little-used roads for the purpose of giving lessons.

Statistics which have just been published in Paris, France, show that there has been a decrease of 24,210 horses there within the last ten years. In 1901 there were 96,698 horses in the city, as compared with 72,488 at the beginning of July, 1911. One omnibus company has 6,500 horses less than it possessed in 1901, while in some of the city wards there has been a falling off in number of horses to fully 50 per cent.

"On to Richmond" by Automobile

Description of Best Routes to Virginia's Capital

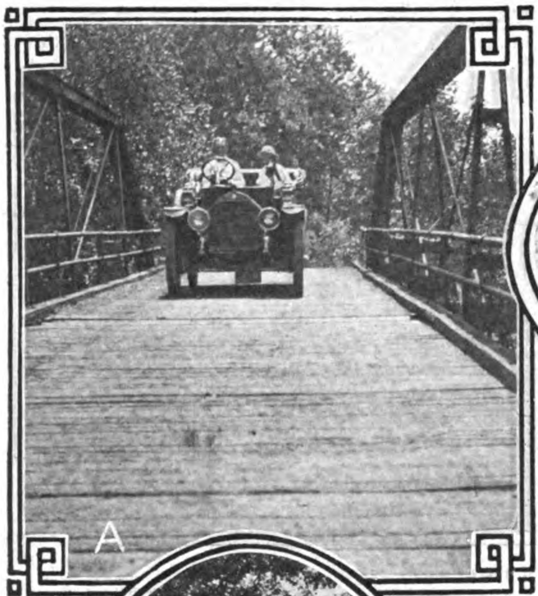
Next November there will be held in Richmond, Va., the most important Good Roads Congress of the year. This gathering will doubtless attract many automobilists from the Northern cities. The following description (reinforced by photographs and an accurate map), which was prepared from the records of the pathfinders of the Touring Club of America, who explored the section in the search for the most feasible routes to the famous capital of the Confederacy, will therefore be most timely.

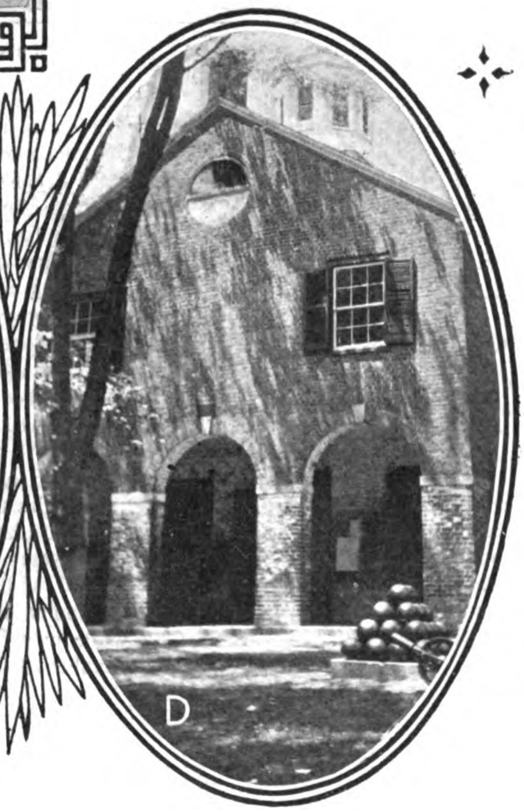
TOURISTS who contemplate making the run to Richmond in November on the occasion of the Good Roads Convention in that city, will find that there are two distinct routes to that historic city, both of which are replete with scenic and historic interest.

Naturally the first itinerary that suggests itself is via Philadelphia, Baltimore and Washington. This, of course, is the shorter and is the route followed by the pathfinder cars of the Touring Club of America on their recent journey southward. The roads across Virginia on this trip, however, are so bad that doubtless the weary tourist will be glad of any other option on the return trip.

While 87 miles farther, the return trip via Staunton, Hagerstown, Harrisburg and Easton may be made in less time because no large cities are passed through and the roads on the average are much superior.

From New York City several distinctly good macadam routes lead to New Brunswick, N. J. The most direct route, however, is that via Newark and Elizabeth, a distance of 25.3 miles. Elizabeth is a residential and manufacturing city. So is New Brunswick, being largely interested in rubber and harness. It holds also one of the termini of the Delaware and Raritan Canal, which runs to Bordentown, on the Delaware, and originally cost $4,-





A—Bridge over Bull Run, near the famous battlefield (See route variation on the map)

B—Orange Court House, showing one of the soldiers' monuments for which this section is famous

C—Monument Avenue, Richmond, with the equestrian statue of General Robert E. Lee

D—Fairfax Court House—George Washington's will is recorded in the office of the County Clerk

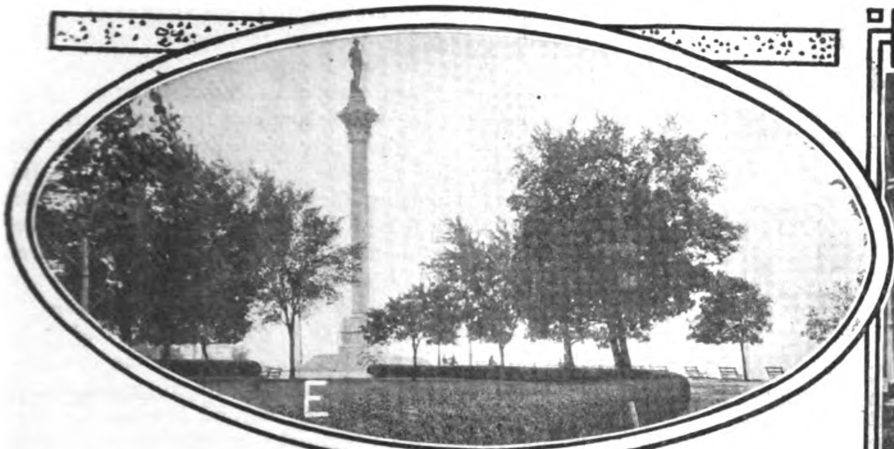
500,000. On the banks of the Raritan, New Brunswick is perhaps best known as the seat of Rutgers College. Like much of the neighboring territory, the buildings of the college were burnt by the British during the Revolution, but during the present century it has advanced considerably, adding a model farm of 100 acres and the State College for the Promotion of Agriculture and the Mechanic Arts.

Leaving New Brunswick on fine State roads, the motorist passes through Monmouth Junction and Kingston into Princeton, the home of Princeton University and one of the chief historic towns of the country. Its name dates from 1724, although the vicinity was settled fifteen years before the end of the seventeenth century. It was then Prince's Town, and is still according to enthusiastic inmates of the university. William Penn is responsible for giving impetus to the settlement there by introducing a number of Quaker families, whose little stone meeting house with its graveyard near at hand may still be seen. But for real genuine luster one seeks out the university. Its Nassau Hall was used as barracks by British soldiers, then as a stable and again as their fortress. Twice the Legislature of the State held its sessions in Nassau, and the Continental Congress fled there to escape the attack of mutinous soldiers in the City of Brotherly Love. The battlefield of Princeton is about a mile and a quarter from the village proper, on the old road to Trenton, known as Mercer street. Here the patriot army met and defeated the British regular troops.

Trenton has many historic points of interest, besides a leadership in the manufacture of pottery and fire clay and the command of the market gardening which supplies New York and Philadelphia. The Quaker City, 35 miles beyond on the best route via Langhorne and Bustleton, is noted for its lukewarm hotel interest in touring motorists and for its Independence Hall, also its City Hall, the largest building in the world, covering 4 1-2 acres, exclusive of the court and costing upward of twenty millions of dollars.

From City Hall the route to Baltimore and Washington lies west on Market street over the Schuylkill and out to Darby over some neglected streets. When the smooth road is reached finally, there is that disagreeable experience of the mile-apart toll-gates reaching to Wilmington, where the traveler crosses the historic Brandywine, near which was established, at the old Swedes' Church, the first Swedish colony in America. From Wilmington, magnificent macadam stretches to Newark, where Delaware, more progressive than Pennsylvania or Maryland, permits the traveler to enter untaxed. On account of the poor condition of the direct road from Newark to Perryville, the following detour (taken from the *Automobile Blue Book*) is recommended: From three-corners at railroad station, Newark, run straight ahead across tracks on direct road through Appleton, Fair Hill, Blue Ball into Calvert. Bear slightly right at five corners and take left fork into Rising Sun. Thence via Battle Swamp into Perryville.

The inevitable toll road leads into Baltimore, the metropolis of Maryland, stretching along the pleasant hills which border a deep estuary of the Patapsco River, 14 miles from Chesapeake



E—Libby Hill Park, one of Richmond's breathing spots, with Soldiers' and Sailors' Monument

F—A glimpse of Bull Run—the fighting raged furiously back and forth across the shallow stream

G—Convicts working on the roads just outside of Gordonsville, Va.

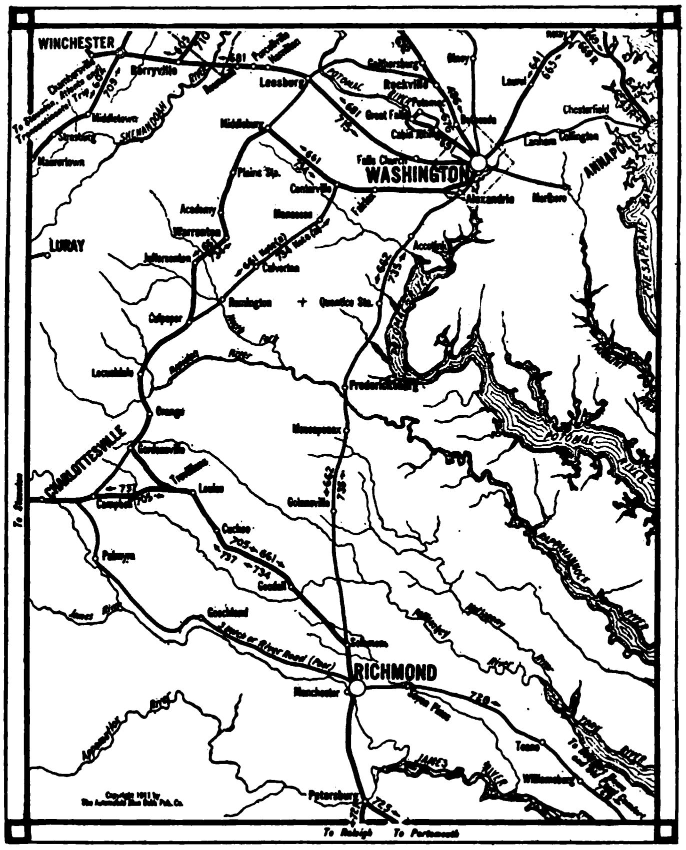
H—Monument at Louisa Court House commemorating the deeds of the Confederate soldiers in the late war

Bay. A stream called Jones Falls divides the city into two parts. Fires more than wars have been the cause of Baltimore's disasters, particularly the great fire of 1904, devastating an area of business property amounting to 150 acres. Johns Hopkins University, renowned for its high standards in medical training, lies along West Monument street. Baltimore is often called the "Monument City," because of numerous testimonials to great men or great deeds of the past, and it has numerous public pleasure grounds, the finest of which is the 700-acre tract called Druid Hill Park.

North on Charles street from Washington Monument in Baltimore one takes the best available trunk route to Washington, D. C., 44 miles away, by striking Edmondson avenue and following the picturesque "Rolling Road" into Relay. So odd a name is due to this place having been the station where changes of horses were made on the first railroad built in this country. At Bladensburg is an old tavern, reached after five miles of jouncy road at Beltsville. Thence the route turns right into Maryland avenue, passing through the beautiful Capitol grounds into Washington.

The pathfinders of the Touring Club of America, by careful study and covering two of the routes between Washington and Richmond, have laid out the following trip, which is entirely practicable although having some very rough stretches. This trip follows a very direct route to Fairfax Court House, which is of peculiar historical interest on account of its having been the place where Washington's will was probated in the year 1800, in which year the present court house was built. The original will is preserved in the Hall of Records in a glass case. There also one may see an original letter from Henry Clay and another from Patrick Henry. The old records date from 1742, but the marriage and birth records were destroyed by the Union soldiers. In front of the Court House is a monument commemorating the killing of the first soldier in the Civil War June 1, 1861.

The route now follows the old Middleburg Turnpike, travel over which is, to say the least, an uncomfortable experience. The pike is composed of crushed field stones whose sharp angles remain unsoftened under the hand of time. On the hills vehicles have turned off the pike and their tracks have cut into the road so that now these side roads will permit the passage of only one vehicle and they must be entered with caution. At that they are preferable to the bumpy surface of the old pike. At Aldie, 39 miles out, a better road is reached which leads through Middleburg, a pleasant little village with tree-lined streets whose overhanging boughs brush the sides of the car. At 45 miles a stretch of winding macadam is encountered, which leads through plains where is located the Orange County Hunt Club. Beyond this is clay road with frequent culverts and stony spots. A four-mile stretch of macadam is again encountered at Bethel which lasts all the way to Warrenton, where there is a nice little hotel and new garage. For the ordinary tourist, getting a late start out of Washington, it is recommended to make a night stop at Warrenton. By rising early the next morning the trip can be easily made into Richmond.



Map showing the best routes between Washington and Richmond, with connection for the South and Southwest (Courtesy of Blue Book)

From Warrenton the direct road to Culpeper is the worst of the trip. The route across to Remington is therefore recommended. Beyond Elkwood a stretch of macadam is encountered which runs with one stretch of clay across to Waverly. The only bad part between Warrenton and Culpeper is the ford across Jonah Run. This should be crossed with care after rains. The T. C. A. pathfinders have some moist recollections of its passage. Culpeper is interesting historically, as several battles occurred in the vicinity and monuments commemorating these may be seen from the road, which now cuts through an old redoubt. Culpeper harbors some very vindictive automobile haters; and on one occasion a fine of $500 and thirty days in jail was imposed on an automobilist for frightening a horse. On the recent good roads tour a fine of $25 was imposed on the driver of one of the cars for "speeding"—and that on a road which is one of the worst in all Virginia!

After leaving Culpeper a welcome stretch of macadam is arrived at near Orange. It is only a short distance thence to Gordonsville, where much work is being done on the road by convict labor. The barracks of the convicts are to be discovered in the vicinity by the curious visitor. Beyond Gordonsville the road follows the line of the Chesapeake & Ohio Railroad with numerous crossings which are all more or less dangerous. Louisa County is one of the oldest in the State, having been cut off from Hanover in 1742. A warm welcome awaits the tourist at Louisa Court House, which holds the record for never having arrested an automobilist; while the good old Virginia fried chicken may be indulged in to the heart's content. The inner man replenished, one may proceed leisurely, for the roads improve as the city is neared.

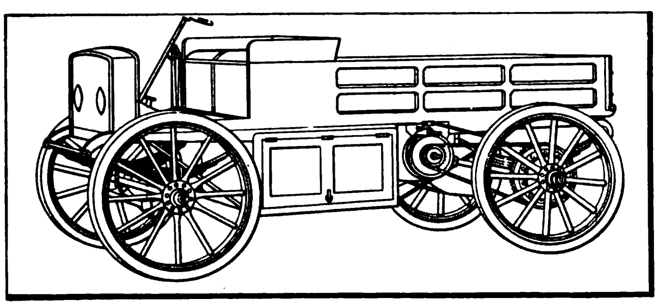
This part of the country is full of Civil War memories. About six miles beyond the Chickahominy River is the site of the old Yellow Tavern, where J. E. B. Stuart fell. A monument commemorates this. Entering Richmond by the official route the traveler passes Washington's monument and later those of Jefferson Davis, Robert E. Lee and J. E. B. Stuart, the route terminating at the Jefferson Hotel, which contains a marble statue of Thomas Jefferson in the rotunda.

The return trip from Richmond is, as previously suggested, preferably made via Staunton and the Valley Pike. It passes through Winchester to Hagerstown. From Hagerstown a good road is followed to Harrisburg, a fine pike to Reading and excellent macadam the remainder of the way through Easton and Morristown, with a choice of several routes from the last-named place to New York City.

Some Recent Electric Products

Leading Concerns Make Improvements in New Models

The popularity enjoyed by electric vehicles in their own particular field continues to grow apace with that of the other motor-driven vehicles, and the enthusiasm of their makers seems to be highly justified when the ever-increasing use of electrics is taken into consideration. Products of the Louisville Electric Vehicle and Broc companies are particularized.



Illustrating the chain drive on the product of the Electric Vehicle Co.

THE Electric Vehicle Company, of Louisville, Ky., has recently brought out two models of light electric delivery cars which represent an effort on the part of the designers to produce a car which will have a long life, low cost of upkeep, high mileage capacity, accessibility and convenience of manipulation for the operator.

The motor, which is manufactured by the General Electric Company, is supported by the car frame just forward of the rear axle. The power is transmitted from the motor to the countershaft by means of a silent chain encased in a dust-proof housing of sheet steel. From the outer shaft to the rear wheels the power is transmitted by means of roller chains. The motor shaft is supported by Hess-Bright annular ball bearings, while the rear wheels are equipped with Bowers roller bearings.

The battery is mounted on a subframe carried just forward of the countershaft. In connection with the 600-pound car the battery used consists of a thirty-cell, eleven-plate lead outfit, while the 1,000-pound wagon carries a battery of fifty A-4 Edison cells. The battery equipment, under normal conditions, will give the car a mileage of from 40 to 55, but if required a heavier battery equipment will be supplied.

The controller is of the continuous torque type, giving four speeds ahead and two reverse. It is located in a rather unique position, being bolted to the dash and covered by a short hood. The wiring of the controller is rendered accessible by removing the dash panel which is held in place by four thumb nuts. The hood besides protecting the controller also serves to protect the headlamps, meter and switches, leaving the body free from the wiring so that it may be removed from the car frame by removing the six bolts which hold it in place.

The frame is built up of channel-section, pressed-steel side members with three gusseted transverse members which are of the same section as the side members. The forward and rear transverse members are connected by truss rods which insure the frame against sagging and give a very light construction. The axles are of I-beam section, being seamless forgings, while the steering knuckles are of reversed Elliott type. All the wheel bearings are of the Bowers type. The springs are semi-elliptics, both front and rear, made of crucible stock.

There are two sets of brakes. The service brakes are contracting bands acting on drums riveted to the countershaft sprockets and applied by a pedal through an equalizer. The brake bands are 8 inches in diameter and have a 2-inch face. The emergency brakes are of the expanding type operating in drums attached to the rear wheels. The brakes are applied by a hand lever and are also equipped with an equalizer. The steering apparatus consists of a semi-reversible worm and gear mechanism working on ball-bearings. The steering column is sloped at an angle of 25 degrees from the vertical.

The car has left-hand control. The control outfit consists of a controller lever and emergency brake levers and is placed on the right-hand side of the driver in the center of the car, the driver being seated on the left-hand side of the car. The service brake pedal is operated by the driver's right foot. The control lever is moved forward for the four forward speeds, and backward for the two reverse speeds. Before passing from the forward to the reverse speeds a latch must be removed, thus providing a safeguard against accidental reverse. The emergency brake is applied by pulling the lever to the rear. An emergency lock switch is provided which opens the circuit when a plunger is pulled out. The plunger locks in open position and may only be returned by use of a Yale key providing against unauthorized use of the car. Lubrication is carried out throughout the car by means of grease cups which are all carefully protected.

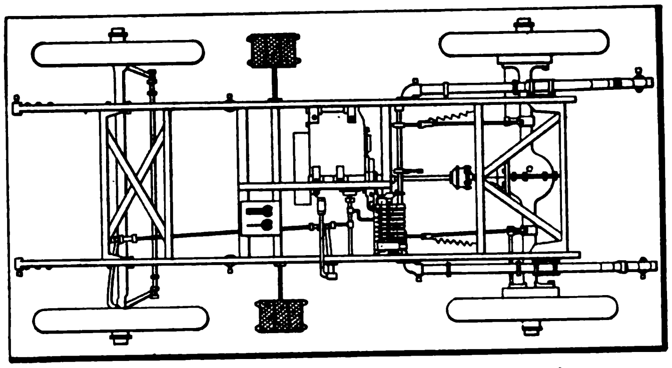
The Shaft-Driven Broc

The Broc Electric Vehicle Company makes six models of electric pleasure vehicles with the shaft drive, the main difference in the models being in the body while the mechanical features are about the same in all the models. The controller is of the continuous torque drum type with five forward and five reverse speeds on the same lever, giving a smooth acceleration of speed without jerking the car or wasting current. A pedal prevents accidental reverse. The controller is equipped with a cylinder lock so that the car can only be started with the owner's key. To prevent the car being accidentally started when the key is inserted, the lock is arranged so that the key can only be admitted when the controller is at the standstill position. The same key fits the doors of the coupé.

The braking system is double, permitting of gradual or quick stopping and assuring safety on steep grades. It consists of a pedal system of expanding Thermoid-lined brakes operating on both rear wheels and a brake operated by the controller lever without using current. When the operator desires to stop he shuts off power, a continuation of this motion applies the brake.

The springs are seven-leaf, semi-elliptic front and three-quarter-elliptic rear, made of special high-grade spring steel, oil tempered and hand fitted, fastened by oil groove bolts provided with grease cups. The rear springs are attached to the frame at two points dividing the weight and lessening the strain on the frame.

The power is transmitted from the motor to the countershaft by a special drive, self-adjusting as to pitch, and enclosed in a dust-proof oil-retaining case. Adjustment for length between the motor and the countershaft is made by an eccentric, without disturbing the case. The transmission is carried from the countershaft to a rear axle by a bevel gear shaft. The drive shaft is of vanadium steel, and all gears in rear housing are made from special steel with planed teeth carefully hardened and ground to gauge within limits of 0.00025 of an inch. Free movement of the rear springs is permitted by the straight line transmission with two universal joints.



Chassis of the Broc Electric, showing method of supporting motor

The rear axle is of vanadium steel, semi-floating type with a drawn-steel housing. The bearings are of the ball type with a positive locking device for adjustment.

The motor is four-pole series wound designed to stand a heavy overload if necessary; it has a wide speed range and is designed to cut down the current consumption on hills to a minimum. The wiring is direct, without resistance coils for low speeds. It is acid- and weather-proof and secured against mechanical strains, the wire cable being covered with 30 per cent. rubber. The steering gear used on all types of body except the roadster is of the folding side-lever type. On the roadster a steering wheel is provided. Ball and socket connections between the steering post and reach rod take up the vibration when driving over rough roads.

The body equipment on all types of cars is complete and has been carefully looked after with the comfort of the owner in view.

Care of Battery Terminals

The dry batteries used on automobiles have reached a state of high perfection, but they have not reached a point where they can be neglected and expected to perform their work in a satisfactory manner. The trouble is often in careless connections.

ONE of the greatest causes for the necessity of calling for the aid of the friendly horse in the early days of motoring were the dry batteries employed as the sole means of furnishing the ignition current. Nowadays nearly every car is equipped with a magneto and the dry cells are used merely in starting the machine. In this capacity they are satisfactory since the work is merely of an intermittent nature.

A great many motorists have trouble with their dry batteries because they do not give them the proper care and attention. In order to have a current of sufficient amperage and voltage it is necessary to connect several cells in series or multiple. This is done by means of short insulated wires which are apt to come loose with a very little vibration. If one terminal is partially disconnected, the whole battery is practically dead, therefore all connections on the primary circuit must be clean and absolutely bright.

Care should be taken to place dry cells in a dry insulated box and to arrange them so that the excessive vibration does not cause them to chafe. A troublesome short-circuit may often be traced to this cause.

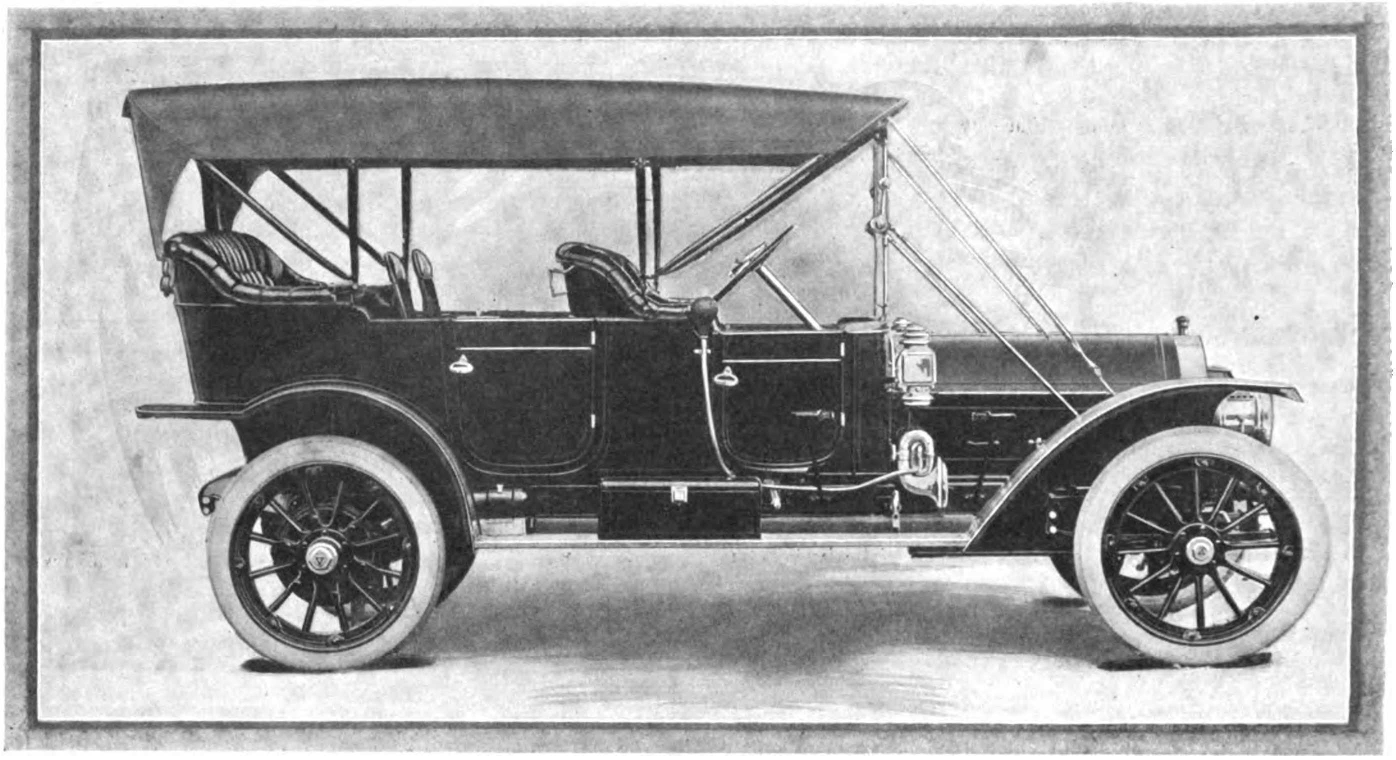


Fig. 1—Model AA Standard seven-passenger touring car, with four-bow top

Six-Cylinder Stevens-Duryea

Mechanical Aspect of the Car

The latest model of the Stevens-Duryea Company, Chicopee Falls, Mass., follows along the line of last year's endeavor. An interesting addition on the Model AA is a permanent air pump for tire inflation. The unit power plant with three-point suspension has been maintained as heretofore, and with the exception of a few refinements the car has remained practically unchanged.

THE motor of the Model AA Stevens-Duryea has six cylinders. 4 1-3 bore and 4 3-4 inch stroke, cast in three sets of two, as can be seen by referring to Fig. 5. The cylinders have T-heads with the intake and exhaust valves placed on the left-hand side of the motor. The flywheel is housed in the extension casing behind the motor, and the crankshaft, which has four main bearings, being machined and ground to close limits, is made from a forging of special crankshaft steel. Two bolts are used to secure the cap of the big end bearing to the connecting rods, and brass shims introduced to facilitate adjustment. White metal is used on all big ends of connecting rods and main bearings. The crank chamber is cast from aluminum, and the cylinders are bolted to it.

The six-throw crankshaft is mounted on four bearings in the crankcase, with two cranks between each pair of bearings. The boxes at these points are connected with the lubricator, the lower half of the crankcase forming a reservoir for oil escaping from the main bearings. The connecting rods dip into this, and the piston, connecting rod bearings and rotating members inside on the motor base are supplied with lubricant from the ensuing splash. The half-time shafts, mounted in the crankcase on either side and parallel to the crankshaft, are driven from it by enclosed gearing as shown in Fig. 9. The main gear wheel G1, which is attached to the crankshaft, drives the half-time gears

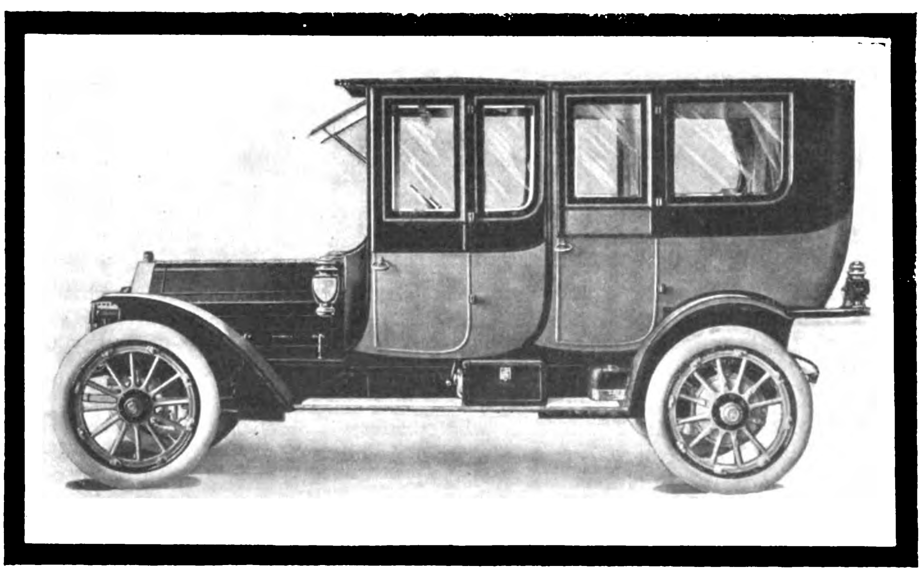

Fig. 2—Model AA Stevens-Duryea seven-passenger Berline

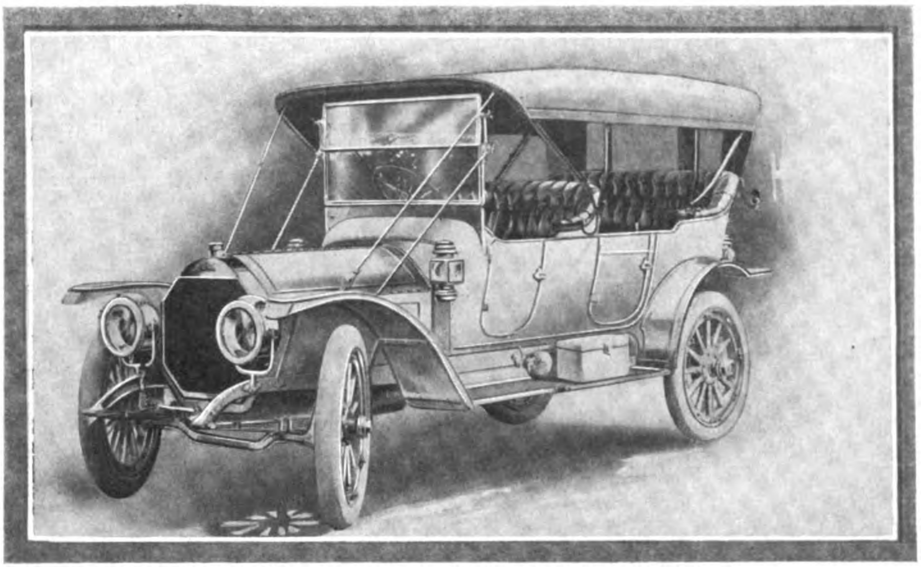

Fig. 3—Three-quarter view of the five-passenger fore-door touring car

G2 and G3. The gear G3 operates the camshaft and the small pinion G4 serves to drive the magneto M, which rests upon a ledge cast integral with the base chamber and held in position by two spring steel bands united by the clasp C. The gear G2 operates the centrifugal water pump which forces the water from the radiator through the pipe W1 in Fig. 7 around the cylinder walls and valve chambers and passing therefrom through the pipe W2 back to the cellular radiator. The radiator R1 is shown in Fig. 6, the water leads W1 and W2 are united to the pipe leading from the radiator by a rubber connection R.

The method of attaching the intake manifold I and the exhaust manifold E to the cylinders is shown in Fig. 6. A single pipe E with the extensions E1 and E2 formed integral therewith are held in position by the strap S1 and the bolts F1 and F2. The intake manifold I is held to the cylinders by the same strap S1, a separate nut and bolt, however, being used to permit this part of the mechanism being dismantled independently. The respective manifolds are surface-ground on the face that contacts with the ground surfaces of the cylinder ports. The carbureter C1 is attached to the manifold in the manner shown The gasoline is supplied from a tank located under the front seats, and the air supply is taken in at the bottom of the carbureter through a small pipe connected with the exhaust manifold. Additional air is provided by means of an automatic air valve. The mixture is controlled by a butterfly type of throttle valve operated by a lever above the steering wheel, and also by a pedal. The vertical tube above the throttle is water-jacketed to assist the vaporization of gasoline at slow speeds and prevent condensation in cold weather. Two valves for cutting off the gasoline supply are fitted directly below the tank, and are operated from outside the chassis frame by two hand levers. A three-gallon auxiliary tank is provided as a stand-by and for emergency. A gasoline gauge, the dial of which is placed directly beneath the front seats, is an integral part of the tank.

At the forward end of the camshaft a spur gear is attached that drives the tire inflating pump P, the gear G3 being held out of mesh with the gear G4 when the pump is not being used.

The ignition in each cylinder is effected by the Bosch double magneto and battery system, with a separate set of plugs for each system. The current for one set of plugs is generated by means of an independent high-tension magneto connected by spur gear with the camshaft; and the other by battery and single-induction synchronous coil located on the dash, fitted with kick switch, push button and special key lock. The timer distributor for the battery system rotates on ball bearings, is absolutely dust-proof and most accessibly located under hood on right side of motor.

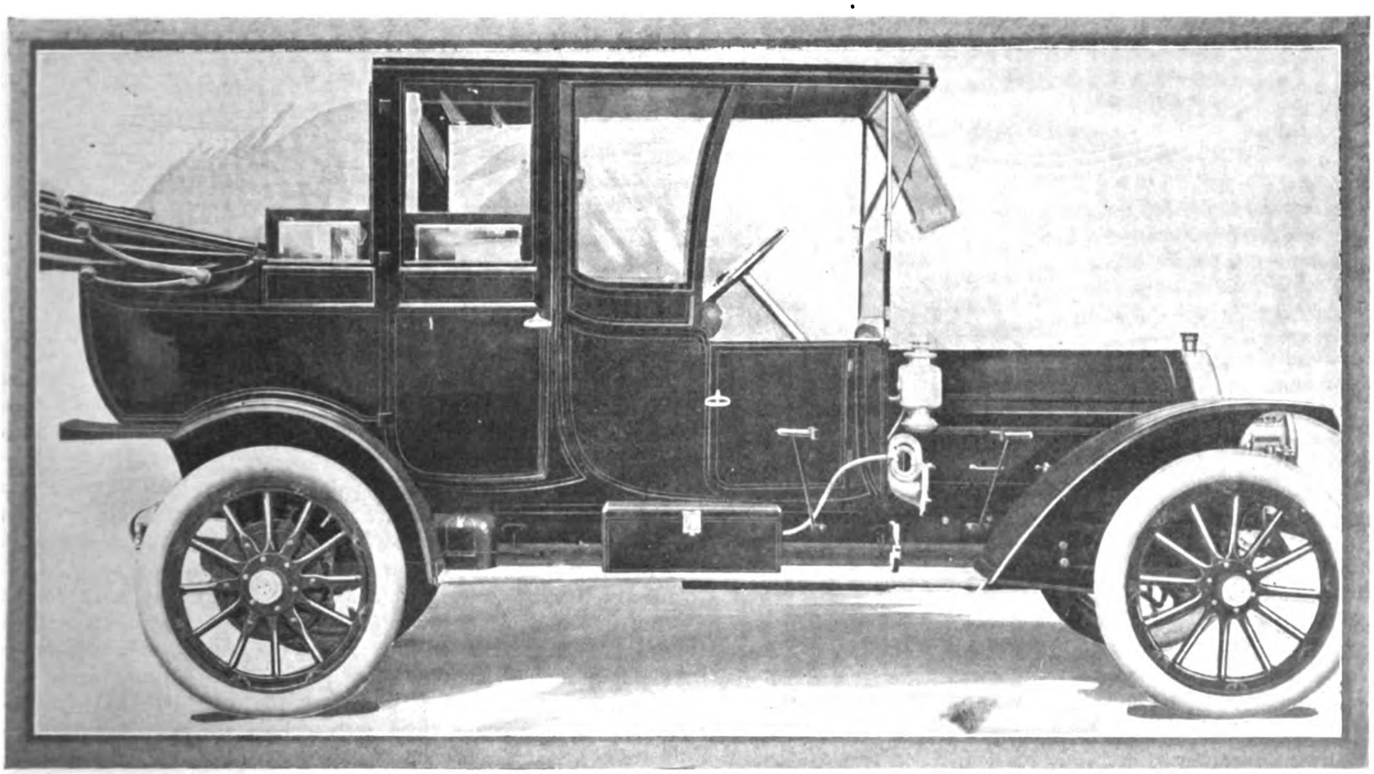

Fig. 4—Three-quarter Stevens-Duryea landaulette fitted to a Model AA chassis

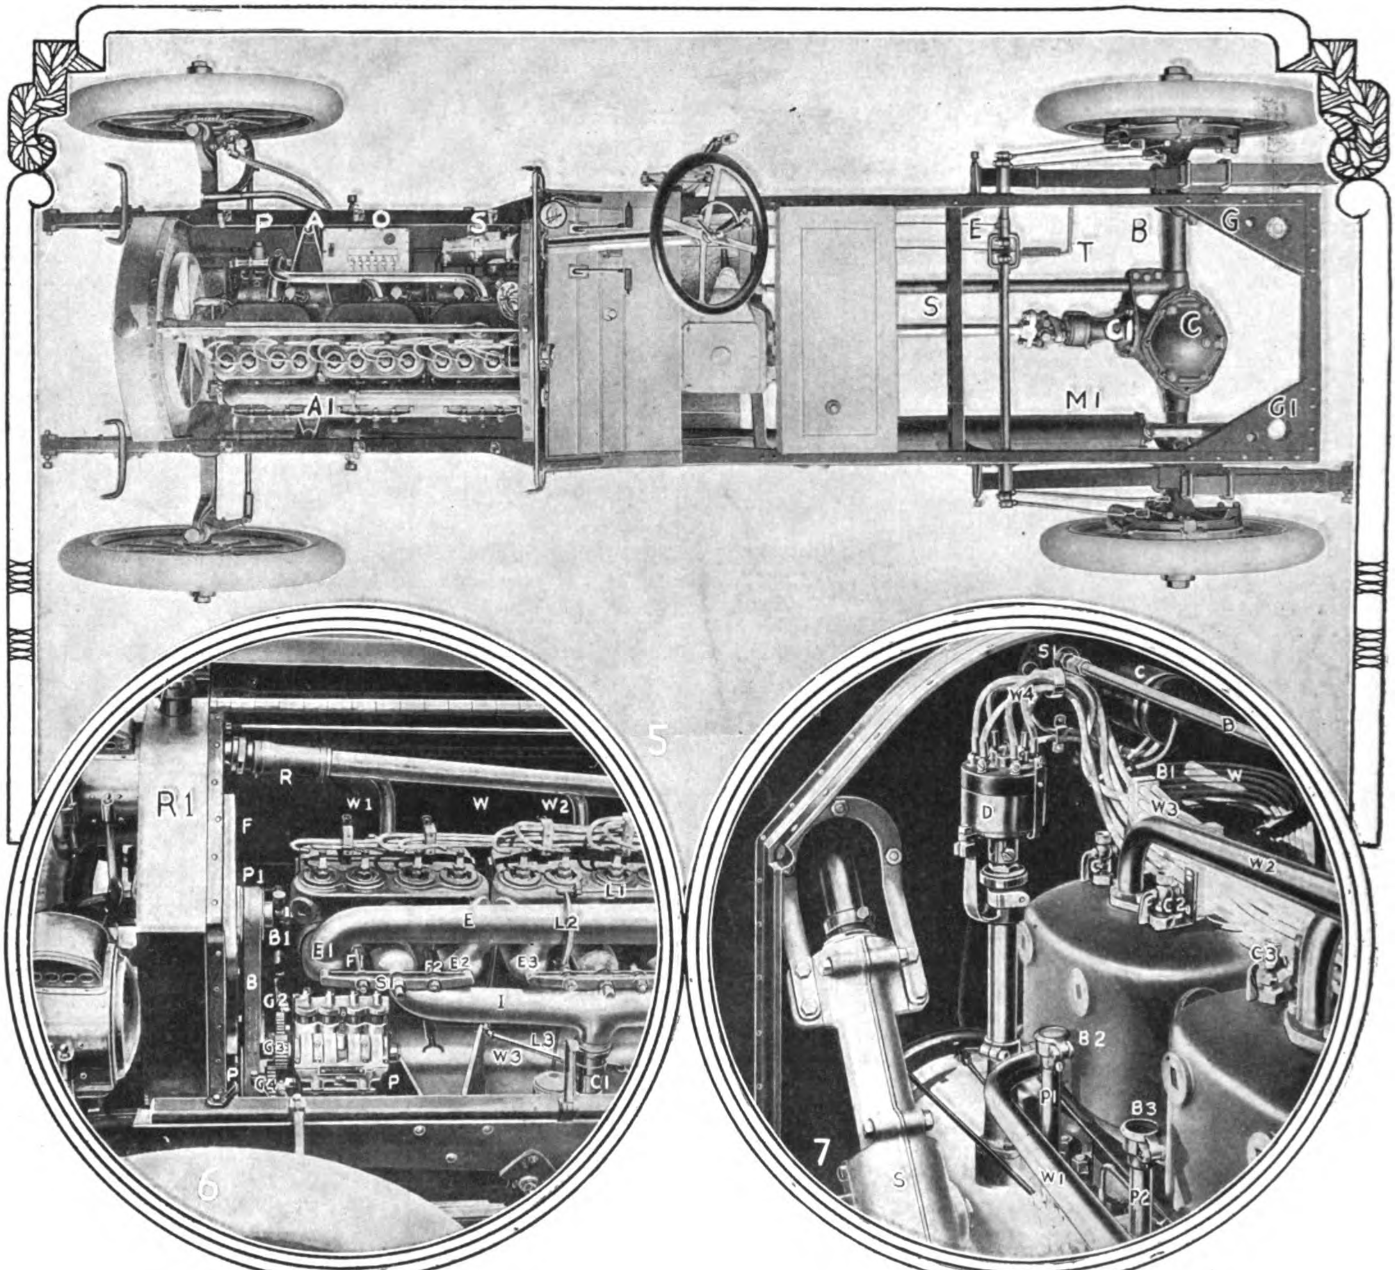

Fig. 5—Plan view of the model AA chassis showing the six-cylinder motor and the live rear axle. Fig. 6—Front end of the motor showing tire inflation pump. Fig. 7—Right-hand side of motor showing distributor and coil on the dash

...e situated on the right-hand side ... hinged covers B1 and B2 which ...red into the crankcase. Com...ner shown in C1, C2 and C3 ...ble by passing a wire down ... piston at any point of the ...hed at the rear end to the dashboard and at the forward end acts as a support for the radiator. The motor is suspended by the two arms A and A1 in Fig. 5, which rest upon the side frames, and as the power plant is of the unit form of construction, with the motor, clutch and transmission encased in a single rigid member, the rear end of the assembly is attached to one of the cross members. This method of assembly eliminates the lining up of the various units and intermediary universal joints.

The clutch, which is of the dry-plate, multiple-disc type, has nine polished steel discs contacting with eight plates double-faced with woven wire and asbestos, having a self-contained thrust. The driving member end of the clutch is connected to the extension of the shaft by square clamps. A ball-bearing ring releases the clutch by means of a forked lever operated by the clutch pedal. The gearset housing forms the rear of the unit power plant casing and has on its underside two lugs cast integral with the aluminum case through which the king bolt of the third point of the support passes; these lugs are bronze metal lined to take the strain off the casing, which is of aluminum. There are three speeds with the ratios of 11.9:1 for low, 6.91:1 for intermediate and 3 1-2:1 for direct drive. The reverse has a ratio

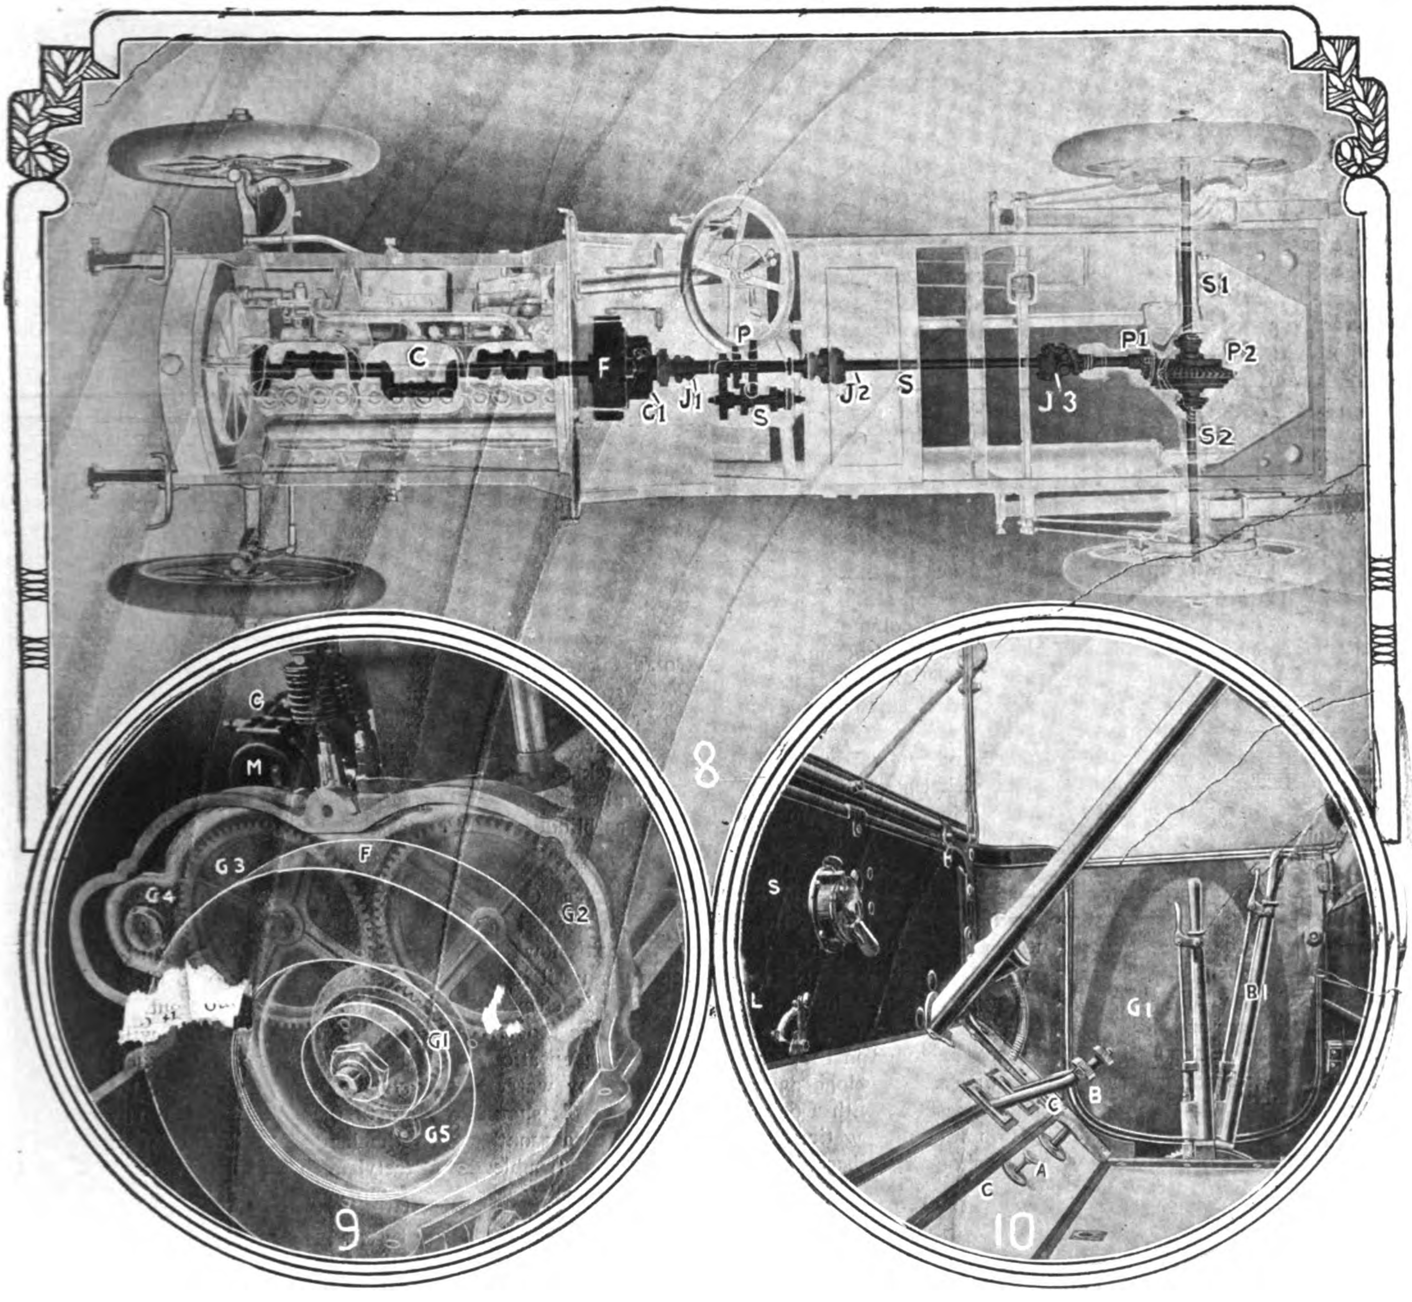

Fig. 8—Silhouette view of the Model AA chassis showing the shafting employed in the drive. Fig. 9—Rear view of the motor through the flywheel showing the timing gears and the magneto. Fig. 10—General view of the front compartment showing the dash fittings, pedals and levers

of 15.35 : 1. The method of taking the drive from the crankshaft through the clutch is shown in Fig. 8; the main shaft of the gearset P is squared to allow the gears to slide. Both primary and secondary shafts run on annular ball bearings, the forward and rear ends of the primary shaft being squared to accommodate the joints J1 and J2.

The escape of oil from bearing caps is prevented by the threads being made perfectly oiltight, and a series of return oil grooves where the shaft extends through. The gears are operated by a lever G1 shown in Fig. 10, working in a quadrant which has a series of ledges forming the stops for the respective gears. Neutral is between low and intermediate, the rising of the latch and forward movement of the lever positively registering the gears in intermediate or second gear; continuing forward without touching the latch engages the high speed or direct drive. The lower gears are engaged in the same manner, only the lever is moved toward the rear of car. As will be seen in Fig. 8, the propeller shaft is not encased, and the universal joints J2 and J3 are of the self-contained type. The cross contains a central lubricating compartment, supplying the four ground arms through a hole drilled centrally to their circumference, while their surfaces are adequately lubricated by parallel ways.

Internally ground and integrally headed cup-shaped arms are pinned and held by nuts to cross arms on drive shaft of gearset, propeller and pinion shafts. By fitting these cups over the arms of central cross, a perfect universal motion results, while the centrifugal force as the joint rotates causes the grease to circulate over the entire bearing surface, under a slight pressure. Not one particle of the lubricant can be forced out as the inner lip of the four cups presses against the outer shoulder of the main cross. To insure the joint from any possibility of leakage, felt washers are placed in the recess where the cups and cross contact on their edges. The forward end of the drive shaft is square and telescopes the rear number of forward universal, a greaser being supplied at this point as well as at the central crosses.

The rear axle is of the full-floating type with a torsion rod T attached to the axle at one end in the bracket B, as shown in Fig. 5, and at the forward end terminating in a ball-socket bracket united to the cross member of the frame. The axle casing extends through and is fitted with a ball bearing on which the rear wheels run. The drive shafts can be removed from the axle through the hubs and the outside extremities are fitted with a series of dogs which engage with corresponding recesses in the hub of the wheel. The carbureter C is removable and it is possible to withdraw the differential after the shafts have been drawn, by loosening the clamps that hold the ball bearings in position. The removal of the cover C1 permits of the withdrawal of the driving pinion and shaft which are forged integral.

Both hand and foot brakes are operated on brake drums 14 inches in diameter, bolted to each alternate spoke of the rear wheels. The brake shoes of the hand or emergency brake are of the internal-expansion type, whereas the foot or service brake contracts upon the outer face of the drum, and are lined with Raybestos. Adjustments are taken care of by accessibly situated thumb nuts, and the equalizing device E in Fig. 5 takes care of the service brake. The front wheels rotate on taper roller bearings, while the load on the upper end of the steering knuckle is carried on ball thrust bearings. The pins forming joints between the knuckles and the forks have the axes arranged vertically, but the stub axles slope slightly downward from the horizontal in order to give the wheels the requisite amount of play. The tie-bar coupling the steering arms is placed behind the front axle. The steering gear itself is of the worm-and-sector type, the worm being an integral part of the steering column, while the sector in the steering case is attached to the drag rod on a taper square. The steering gear is passing through the frame by means of two long bolts, and the drag rod is carried inside the frame ending in a ball-and-socket joint.

The frame is upswept at the forward end and offset over the rear axle, being pressed out of chrome-nickel steel, heat-treated, and the side members are held together by four cross-member gusset plates G and G1, being fitted for increased strength.

Semi-elliptic springs are used at the front, being 48 inches long, and the rear suspension is taken care of by three-quarter-elliptic springs. The springs are held in special clips with integral plate at the top, thus preventing drilling the springs.

Five open touring bodies, ranging in passenger capacity from four to seven, and three types of seven-passenger enclosed types are fitted to the standard Model AA chassis. The prices of the touring cars range from $3,750 to $3,900. Included in the equipment is a four-bow top, the side curtains and envelope and an adjustable glass windshield. All models are fitted with a 60-mile dial speedometer, four-cylinder air pump for inflating tires, side, tail and acetylene headlights, gas tank, shock absorbers for the rear axle and quick detachable rims.

When Judgment Whispers Don't

DON'T mistake the silence of inactivity for silent performance.

DON'T pin your faith to every ancient proverb: one old saw has it that the wheel that turns gathers no rust.

DON'T rely too much on your chauffeur's eyesight just because he occasionally sees double.

DON'T forget that the bucolic Vidocq's idea of speed is apt to be exaggerated wherever an automobile is concerned.

DON'T go to extremes in automobile styles; in this age of rapid progress *passé* is just around the next corner.

DON'T knock the motor that knocks; the fault may be your own.

DON'T fail to remember that ill-mated parts must clash and that incompatibility of temperament is a legal ground for divorce.

DON'T allow an infected part to contaminate its neighbors; quarantine the car until the trouble is eradicated.

DON'T fail to scrutinize more closely than usual the credentials of the second-hand automobile that is painted in gay colors.

DON'T rely too much upon a 250-word guarantee; in the case of a stiff hill a good-performing motor is more to the point.

DON'T take liberties with a grade-crossing; play things safe—stop, look and listen.

DON'T forget that adages, like dreams, frequently go by contraries; a horseshoe in some cases brings anything but luck to the automobilist.

DON'T allow the jejune narratives of the blatant salesman to act as blinders when on a still hunt for a good car.

CONDENSER OFTEN MISPLACED—The average motorist frequently places the acetylene gas condenser or its substitute in some position where it becomes caked with mud and is almost forgotten until it is full and the lamps begin to flicker. Then the mud is cleaned from it and it is drained out. It should be placed so that it is close to the lamps, where it will catch all of the condensation from the gas going to the burners, and in addition any water that may enter the burners due to washing of the car. It should be emptied from time to time, say once or even twice a month, when the lamps are in regular use. The majority of troubles with acetylene lamps are due to lack of a condenser and to the use of too small metal tubing.

Looking for Something New

Discussing Some Piston and Rotary Valve Motors

In the present article it is proposed to show several ideas that have been developed along the rotary sleeve valve principle, together with a variety of piston valve motors, patents for which have been taken out in various countries. Steam valve practice has been resorted to in the case of the Lewis motor, and it is interesting to note, quite apart from the shape of the valves employed, the various methods employed in their operation.

IN the piston-valve type of motors, some of which have already been discussed in previous issues together with those described in this article, specially formed cams are employed to obtain the combination of quick opening and closing and the necessary period of dwell during the compression and firing strokes. If the time ever arrives when the majority of the motors of the valveless type that have been patented come to be used commercially, the question of prior right and infringement will present a knot that will be difficult to unravel.

The Lewis Slide-Valve Motor Follows Steam Engine Practice

The section of the motor shown at (BD) is the idea of Edmond W. Lewis, Coventry, England, and as far as the actual valve gear is concerned it is somewhat similar to the action of the slide valve used in steam engine practice. The slide valves A and C in Fig. BL consist of flat cast-iron plates about one-half inch in thickness, provided with slots B and D. The valve is caused to reciprocate through the action of the connecting rod F running at one-fourth speed of the crankshaft and driven therefrom by a suitable gearing.

The slow speed of operation should materially tend to reduce friction and permit of better lubrication. Each valve is provided with a balanced stationary valve seating. The valve seating or packing blocks S and S1 are kept in continuous working contact by the pressure of eight small coil springs S2, S3, S4 and S5, which are retained in position by recesses in the back face of the block. The covers H and H1 are detachable and the sectional drawing shows the position of one of the sliding blocks during the exhaust stroke. The valves are lubricated under pressure at the points L and L1.

Marshall Rotary Disc Valve Motor of Simple Construction

Fig. BE shows two sections through the Dale Marshall motor. The section through the head of the cylinder shown at (B) shows the disc valve with a port hole P, which is caused to rotate and cover the intake and exhaust ports I and O. The valve plate V in (A) is connected by means of a pivot R at the periphery of the valve plate V to teeth, which are in mesh with a tooth wheel W situated in a recess S and driven by the vertical shaft A by oblique and eccentrically formed gearwheels D and E, which by reason of the eccentric movement of E transmit a variable movement to the shaft A and the valve plate V. This variable movement provides a reduction in the speed of the valve plate V when it is exposed to the compression and firing of the explosive mixture. The cylinder head is in the form of a cover secured by screws X, which facilitate the removal of the valve for inspection.

Von Lauerer Uses a Rotary Sleeve in the Cylinder Head

The method employed by Karl Cziharz Edler von Lauerer is applicable to any number of cylinders, and it will be seen from the accompanying illustration BF that the valve mechanism is placed directly in the head of the cylinders and communicating with them by means of a single port P1. Running on ball bearings is a sleeve S1 driven from the crankshaft by means of a silent chain, to the pinion P2, which causes the sleeve to rotate. Within the sleeve there is a pipe B with suitable slots cut in it, so that as the chamber C2 passes over the passageway P1 the gases are admitted to the cylinder through the suction of the piston. Exhaust is carried away through the sleeve S1, the exit being through slots E. The intake manifold B, being placed as it is inside the sleeve S1, will cause the mixture to be previously expanded, but it is a question whether the expansion of the sleeve S1 caused through the burning gases passing through it will not have a deleterious effect upon the clearance.

The Empress Motor Utilizes a Water-Cooled Rotary Valve of Simple Construction

The Empress engine shown in section in Fig. BG hails from the North of England. The valve V is driven by worm gearing from the crankshaft and runs at one-quarter speed of the latter. The motor is of the four-cycle type and has four cylinders cast en bloc approximately 4 x 5 inches bore and stroke. The cylinder head casting, which is water-jacketed at W and W1, is so formed that a water-jacketed and ported sleeve running the whole length of the block over the combustion chambers acts as a rotary valve. Suitable glands are provided for the water-jacketings. The intake and exhaust manifolds are respectively bolted to the cylinder casting by means of the clamp C and the nut B. The illustration shows the motor at the moment of induction.

The De Dion-Bouton Company Patents a Rotary Sleeve Motor

The engine is provided with two cylinders A (as shown in Fig. BH), surrounded by a water jacket A1 common to both. The combustion end A2 of each cylinder is reduced and the corresponding portion A3 of the water jacket is similarly reduced. Around each reduced portion A3 a rotary sleeve valve B is mounted. Each sleeve is provided with teeth B1, which mesh together and receive motion from a gear wheel C that engages the teeth of one of the sleeves. Surrounding the sleeves is an outer casing D that fits the sleeves and also fits against the wall of the water jacket above and below the sleeves. The walls of the outer casing D are made hollow and are open at the end, as is also the water jacket A1, and these open ends are covered in by a plate E. This plate is provided with interior passages E1 that communicate with the open ends of the water jacket A1 and the hollow casing D, so that water can flow from the interior of one member to the other.

The Griffith Utilizes a Rotary Valve in the Shape of a Cone

As shown in Fig. BI, the valve stem V is rotated by bevel gearing, whilst the head is drawn on the seating by means of the spring B. The port is formed by the slot C, which is cut in the valve and in the plan section the relation of the slot C to the exhaust port D and the inlet port F is shown. There is a part of the cylinder wall shown at E between the intake and exhaust passage-ways which prevents any intercommunication between inlet and exhaust gases.

A German Invention Along the Lines of the Knight Valve

The sleeve valve shown in Fig. BJ needs little explanation, in view of what has already appeared in the recent issue of The Automobile concerning sleeve valve motors. The operations of the sleeves C and D are controlled by the eccentric B, which is placed over the heads of the cylinders, the sleeve C being operated by the connecting arm C1 and the sleeve D by the connecting arms C2 and C22. The invention was registered by the Deutsche Automobil-Konstructions-Gesellschaft.

Small Motor Is of Rotary Valve Type

The four cylinders, D, E, F and G, of the Small motors, shown in Fig. BK, are arranged around the rotary valve. Two of these cylinders, D and E, are in the longitudinal central plane of the engine, whilst the other two cylinders, F and G, are inclined from opposite sides of the central plane towards the shaft axis. The pistons in the cylinders D and E are connected by means of rods with the pins A and C respectively, whilst the pistons in the cylinders F and G are connected by means of rods to the same crankpin B. The crankpins of the end throws are in line with one another and with the pin B of the remaining throw, which is set at an angle of 180 deg. relatively to the pins A and C.

The rotary plug type valve H has a central inlet passage J leading axially into one end and an outlet passage K leading from the opposite end. The inner ends of both these passages merge by easy curves into the required shape of their respective ports at the circumference of the plug upon which they bear, forming side by side the openings M and N, which are at the same level.

A partition separates the passages J and K, and the openings M and N are separated by a portion of the plug. The valve H operates vertically in a liner O, provided with ports P and R communicating with the cylinders D and E respectively. These ports are radial with respect to the valve H, the rotation of which puts each cylinder port in turn into connection at the proper times with the inlet and outlet passages J and K. The construction of the valve and liner is such that the valve can be drawn out of the liner endwise from the top of the engine, and the liner O is continued at its lower end to make a detachable union or other joint with an exhaust pipe S.

The parts are so arranged that upon disconnection of the exhaust pipe the liner O itself, together with the valve and ball race on which the rotary valve H works, may be withdrawn as a whole from the engine.

Within the liner O an inner circumferential gutter T is provided beneath the edge of the valve H. This gutter is intended to intercept any lubricant that may drain from be-

Fig. BJ—A German invention along the lines of the Knight motor, the sleeves being operated above

Fig. BK—Two sectional views of the Small rotary valve motor in which one valve serves the four cylinders

tween the plug and the liner, and the lubricant thus intercepted is conducted by a return pipe to the crank case. Between the valve and the inner circumference of the liner or valve seat, packings are provided, as shown. The valve H is rotated from the engine shaft by a bevel gear.

The cylinders F and G communicate with ports V and W respectively, and the valve H in its rotation successively establishes communication between the inlet J and each cylinder and between the outlet K and each cylinder in the manner shown in the illustration.

In view of the fact that all the cylinders are controlled by one valve, and since the valve itself cannot be modified to suit the angle between the axis of the cylinders F and G, and because the pistons operating in these cylinders on the same pin do not come simultaneously to the extreme of their strokes, it becomes necessary to compensate for the time lag between the pistons in the cylinders F and G; hence the ports V and W are set so as to have a certain amount of advance and lag. The requisite amount of advance and lag for opening and closing is obtained by raking the ports V and W to a greater or less extent instead of making them radial with respect to the valve H.

Daimler Motoren Gesellschaft, Manufacturers of the Mercedes Car, Have Registered a Patent for Overhead Rotary Valve

Fig. BL illustrates the rotary sleeve patented by the Daimler Motoren Gesellschaft. Those who have worked on rotary sleeves will be interested in this construction, since hitherto the chief argument against this class of valveless motor has been the difficulty of keeping the sleeve tight. Following is an extract of the patent claim of the makers: The patent relates to a rotary sleeve valve for internal combustion engines, the sleeve space being partitioned by means of a wall, resulting in two spaces of varying cross-section, as shown in Fig. BC. The longitudinal partition is made of thinner or more elastic material than the sleeve itself, resulting in an expansion of the partition by the hot gases, whereas no expansion takes place on part of the sleeve. Another improvement is seen in Fig. (G) of the illustration, showing a wavy surface of the partition or one or more expansion grooves, taking up the expansion of the partition metal. Fig. (A) in BC shows a cross-section through the sleeve through the cylinder head, while Fig. (B) is a top view of the rotary sleeve, and Fig. (C) an end view. (D),

Fig. BR—Transverse and longitudinal sectional views of the Niclausse motor with rotary sleeve valves

Fig. BS—Sectional view of Payne piston valve, showing relation of working cylinder to valve

(E) and (F) are sections made through the lines AB, CD and EF, respectively, which are drawn in Fig. (B). In the sleeve 1 the partition 2 is provided, dividing the sleeve space in two longitudinal chambers, the shape of the partition being such as to make the chamber for the fresh gas increase in cross-section from the entrance side toward the other end, while the exhaust-gas space increases in the opposite direction. In Fig. (C) the cross-section of the inlet end of the sleeve is cross-hatched vertically, and horizontally at the other end. The partition 2, designed helicoidally to bring about this shaping of the two sleeve chambers, is much thinner than the sleeve itself.

Zeitlen Motor Has Overhead Piston Valves

This invention relates to the reciprocating piston valve for internal combustion engines, and of the kind which is spring-urged in one direction and shifted positively in the other by means of a cam or a layshaft. The hollow piston valve A, shown in Fig. BM, controlling the admission and exhaust of the working fluid to and from the cylinder B, is arranged to slide in a transverse valve casing, which is secured to or integral with the cylinder head being water-jacketed. There are three ports in the valve cylinder casing, the one at D leading into the working cylinder and E and F in the opposite wall of the valve cylinder, E communicating with the intake manifold I, and F communicating with the exhaust manifold E1. The piston valve has two sets of ports in opposite walls, the induction ports I1 and I2 being adapted to register simultaneously with the ports E and D respectively, and the exhaust ports F1 and F2 with the ports F and D respectively. The compartment of the piston formed by the walls acts as a mixing chamber.

The spring G urges the piston valve towards the induction position, and is enclosed within and compressed between the pocketed end wall and the cover H, which has an air hole. The sectional view of A (BM) shows the valve in the position of exhaust by means of a cam C1, the contour of which is such as to allow the spring to force the valve in the opposite direction during the suction stroke and to hold it so that the ports in the cylinder are covered during the compression and firing strokes. The cam actuates the valve through the lever L fulcrumed at L1 and fitted with a roller co-operating with the cam, the piston valve being connected with the lever L by the link K, an adjustable stop being provided to regulate the closing.

Serex Motor Utilizes Two Sleeves to Operate the Gas Ports

This motor, as shown in Fig. BN, has two sliding members, one co-axial with and outside the piston and having mainly for its object to ensure the gas tightness of the cylinder, and the other situated outside the cylinder serving as a distributing valve to place the cylinder in communication with the inlet or exhaust. The engine comprises a piston A acting through a connecting rod B upon a crankpin C. The piston moves in a cylindrical sleeve D reciprocating in the cylinder E. The sleeve D has no port and is provided at its upper end with a packing segment F. The sleeve D receives a reciprocating movement from an eccentric G mounted upon a shaft H driven by the crankshaft and turning at a speed half that of the latter and in the same direction. At the side of the cylinder E is arranged a smaller cylinder E1 in which moves a cylindrical slide valve I driven by a second eccentric J mounted upon the shaft H. This slide valve is provided with an annular recess K and an annular chamber L, in whose walls are formed two ports M and N. The cylinder E is provided with a port O and the cylinder E1 with two ports P and Q into which the admission pipe R and the exhaust pipe S lead. Above the valve I is a chamber T closed by a plug T1. The air enclosed in the chamber forms an air buffer and holds the slide against the eccentric.

The Wolseley Motor Employs Sliding Piston Valve with a Cam That Allows Periods of Dwell

The cross-sectional view of the Wolseley motor shown in Fig. BO is similar in many ways to other motors of this type, which have been described previously. The piston P1 is placed inside a separate cylinder controlling the ports A and B and on the right-hand side of the illustration (BO) is shown the cam mechanism which causes the valve to reciprocate. It will be noticed that the shape of the cam is such that the valve stands substantially stationary in midway position when it is rapidly moved to its extreme position for the exhaust stroke, and next passes quickly across to the extreme position for the inlet stroke, after which it returns to the mid position for the compression and working strokes. The valve chamber extends above and below the inlet port of the cylinder and is provided in the upper portion with the inlet port A and the lower with the exhaust port B. There are no crossbars or other impediments in this type of construction to impede the flow of the gas or to become overheated through contact with the heated exhaust.

Hiscock Uses Two Concentric Piston Valves Sliding One Inside the Other

The piston valve shown in Fig. BP is the invention of H. W. Hiscock and A. L. Reeves. The two pistons, A and B, reciprocate in the valve chamber placed parallel to the working cylinder. The valve A is closed at the top by a cap C, while the valve B is open at the top. Both valves have slots cut in them which register with the port E according to the cycle. When the inner valve C is lowered the gas can enter into the cylinder over the top of the cap, from the intake manifold which is attached at I. When the valve A, however, is raised in the position shown in the illustration the exhaust gas escapes through the two hollow valves and out through the passageway F. In any intermediate position of the two valves the ports are closed.

Mercedes Busy in the Patent Office With All Sorts of Valveless Motors

As long ago as November, 1909, the Mercedes company were granted a patent for a valveless engine as shown in Fig. BQ. The idea is very simple and needs little explanation. In the cylinder head of a motor operating on the four-cycle principle there are two concentric, concave discs, each attached at the upper extremity to gearwheels G and G1. The valve A is attached to G1, and the valve B, whose spindle S passes through the hollow spindle of the valve A, is attached to the gear G by means of a key. Both valves are provided with ports and rotate in opposite directions and the port C is adapted to register with the inlet port D and the exhaust port E. The valves are rotated by an overhead shaft through suitable gearing. The application shown is one of several made at the time when the original patent was applied for. Whatever lubrication there may be for this type of valve is not shown in the patent application.

Niclausse, the French Boiler Makers, Are Responsible for a Four-Cylinder Motor with a Single Rotary Valve

The section of the motor seen in (BR) shows the method employed by G. & A. Niclausse, of France, of controlling the intake and exhaust gases of a four-cylinder motor working on the four-cycle principle. The cylinders A, A1, A2, A3 are provided each with two ports in their heads shown at P and P1, which are controlled by the rotating valve V1, working in the chamber C1, which has a central annular chamber C2 communicating with the gas inlet pipe. Ports P2 are made in the portion of the valve V1 opposite to the annular chamber C2, which ports place the inside of the valve in communication with the chamber C2 and therefore with the admission. The valve V1 is provided with four ports P3 set at suitable angles to one another and adapted to the place opposite the opening P in the head of the cylinders in such a manner as to place the cylinders in communication with the gas admission. An exhaust pipe E in connection with the casing C1 by passageways, which lead into the pipe in planes corresponding to the exhaust ports P1. The valve V1 is provided in this plane with recesses R, R1, R2 and R3, set at angle to one another, which serve to place the heads of the cylinders in communication with the exhaust. The valve chamber is surrounded by a water-jacket, which is the continuation of that surrounding the cylinders. Valve V1 rotates at half speed of the crankshaft and is driven by means of a chain C3 from the sprocket S1 to the sprocket S2.

Payne Piston Valve Offers Little Resistance to the Passage of the Gases

The gases in the Payne piston valve motor, a section of which is shown in Fig. BS, are controlled by a reciprocating cylindrical piston valve V which is parallel to the axis of the working cylinder C and adapted to be reciprocated with a gas-tight fit within a cylindrical valve chamber C1 cast on one side of the main cylinder C. The cylinder port P and inlet and exhaust ports I and E respectively open into the valve chamber CI, on opposite sides of the same, but not in the same plane. The valve V is provided with two ports P1 and P2 which converge toward one another, on the side adjacent to the cylinder port P and transversely through the cylindrical valve body.

The ports P and P1 in the valve may be arranged so that they unite in a common single port P3 on the side which control the cylindrical port P, while their opposite ends diverge and may be any distance apart. The arrangement is such that one of the ports P1 or P2 in the valve is open at its inner end to the cylinder port P during the compression and firing strokes, so that the valve proper is not subjected to any side pressure. The other end of the port would be covered and closed by the solid wall of the valve casing, which takes the pressure. The inlet and exhaust ports I and D, which are formed in the outer wall of the valve chamber, are provided with automatic non-return check valves C1 and C2, which may be furnished within and carried by the valve cases V1 and P2, thus preventing the exhaust gases being sucked into the cylinder during the suction stroke. The valve is caused to reciprocate by the eccentric E1 driven by the suitable gearing from the crankshaft and attached to a stud extension of the valve by an arm and a pin.

Relation Between R. P. M. and Piston Speed

In the accompanying chart the inquiring motorist is afforded a ready means of ascertaining the speed of piston travel when the stroke of his engine and the number of revolutions per minute are known.

WITH the aid of the chart here shown (which was drawn by J. Dalrymple Bell, an English automobile engineer) it is possible to ascertain the piston speed of any engine in feet per second when the revolutions per minute and the stroke are known. It is also possible by means of this chart readily to find the stroke or revolutions per minute when the other factors are known. To ascertain the piston speed in feet per second, find the point formed by the cutting of the vertical line from the stroke (in inches or millimeters) and the radius corresponding to revolutions per minute. The feet per second of piston speed will then be found horizontally on the left of this point. As an example, if the stroke be 5 inches and the speed 2,000 revolutions per minute, the thick vertical line above the figure 5 on the lower scale must be followed until the diagonal line corresponding to 2,000 revolutions per minute is encountered. Reading then on the scale in a horizontal line to the left, it will be seen that the piston speed is exactly 28 feet per second or 1,680 feet per minute. As an aid to the use of this chart, a piece of black cotton may be passed through a small hole at the point of origin (the lower left-hand corner), and may be used instead of a straight-edge for those radii not drawn in, but the extremities of which are indicated on the top and right-hand margins.—*The Autocar*, July 15.

It Stands to Reason—

THAT the best roads are the scenes of the worst accidents.

THAT carrying coals to Newcastle is a paying business as compared with the production of second-rate automobiles.

THAT the noisy automobile is in the same class with the common scold—a nuisance to the neighborhood.

THAT a scrobiculated cylinder will be all the better for a little grinding.

THAT a quiet-performing motor is a sedative to the owner's mind.

THAT in the building of good roads unless new methods are employed the remedy is worse than the disease.

THAT the course of reasoning should be from the effect to the cause and then good roads will follow.

THAT isolated stretches of good roads do not improve matters to any great extent.

THAT an automobile is a boon only as it imparts at once pleasure and instruction.

THAT the downward road is an easy one and the steeper it is the better it will show the hill-climbing qualities of the car coming back.

THAT to err is human, but to forget the gasoline a second time is unpardonable.

THAT it is better to have an oil gauge on the dash than to be worrying all day lest the pump be not working.

THAT there is no sense in offering one's self up as a sacrifice just to prove that a railroad corporation is criminally negligent.

THAT in negotiating a grade crossing it devolves upon the automobilist to exercise ordinary caution.

To Remedy Clutch Troubles

This portion of an automobile's mechanism has a reputation for cantankerousness at times. A trio of its vagaries are here discussed, with suggestions as to how to remedy them.

THE average clutch has its vagaries; sometimes it may be just right; at others it may be slipping; again, it may be what is called "fierce." The second condition manifests itself in such pleasant situations as climbing a hill when, with the engine running at its highest speed and the proper gear engaged, the car starts to run backward instead of forward. Or on the level when, with the engine racing and the high gear in, no speed results.

The last condition shows itself in the sudden jumping forward of the car when the clutch has been let in, or it may even be so severe as to shear off the bevel driving gear when used with studded non-skid tires or any form that will not slip easily.

To repair the first, look at the leather; if this is all in good shape with an apparently good surface, but has lubricating oil on it, wash the surface well with gasoline. It is not a bad idea to roughen the surface of the leather a little with a coarse file.

The harsh or fierce clutch is remedied by the application of a proper oil for this purpose. Castor oil is universally used and a good way is to soak the complete clutch in it overnight. This will cure a case of harsh leather, but it may be that the trouble is only a lack of adjustment of spring tension. Usually there are an adjusting nut and a locking nut. Back off the latter and make an adjustment. Then tighten the lock nut to retain it. For the beginner it is better to adjust a little at a time and make several successive jobs of it than to try to do it all at once. But always adjust it as soon as possible.

POOR COMPRESSION NOTICEABLE AT LOW SPEEDS—Poor compression will not have as much effect on the motor at high speeds if the leakage is, as it is in most cases, small. Since there is such a short time which elapses between the compression and expansion strokes at high speeds the gas has a very small chance to leak out. At low speeds, however, the difference in power is very evident and the engine power falls off very rapidly at a time when it is most desired, as in hill climbing.

LUBRICATION ON HILLS—Sometimes it will be noticed that a motor will slow down on a hill where it has usually picked up. This is often due to over-lubrication of one or more of the cylinders, which will clog the muffler with soot and greatly increase the back pressure. If proper precautions are not taken, this will often occur where the oil flows about freely in the crankcase and runs down to one end when the car is tilted, as in going up or down hill.

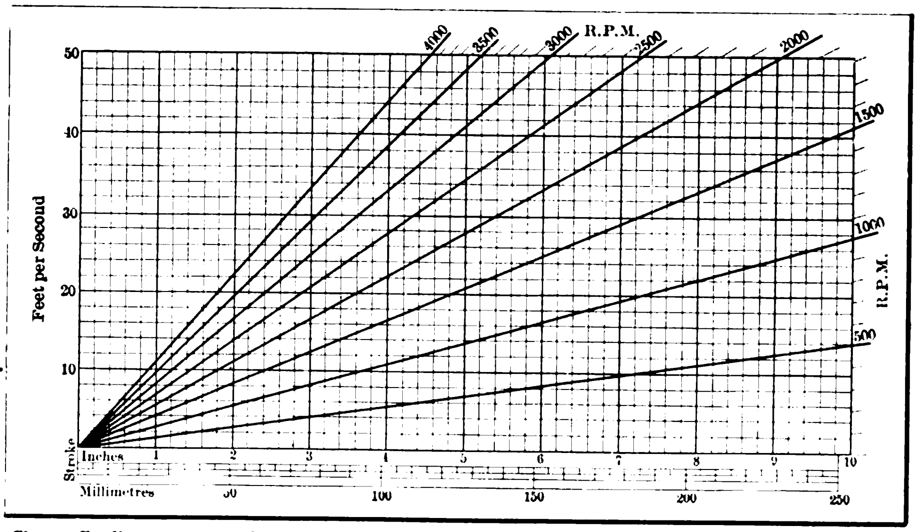

Chart affording a means of ascertaining speed of piston travel when stroke and R.P.M. are known

What Other Subscribers Have to Say

Handy Way to Get Out of a Rut

Editor The Automobile:

[2,770]—The other day while out on a short tour in a part of Long Island that has evidently, and perhaps with reason, not been explored to any great extent, I found myself stuck fast in a rut. There is no excuse for the roads being in the condition in which I found this one, as it was almost impassable. I had a very hard time getting the car out of the position in which it had lodged itself, although I had a good rope along with me and in fact would not have got out as easily as I did if I had not had timely aid from an accidental country wagon. Could you through your columns give a method of procedure in a case of this kind, as I am sure it would be of general interest? R. T. C.

Long Beach, N. Y.

The matter of ruts is one that will crop up now and then in spite of our advanced stage of civilization and the vigor with which the good roads campaign is being pushed in New York State. There is a handy way of getting out if you are fortunate enough to have a rope along with the car and the rut happens to occur near a handy telegraph pole or tree. The accompanying cut (Fig. 1) depicts a method which was much used in the old days of the horse. A turn was taken about a convenient tree or post, then a smaller pole was placed in the position shown to act as a fulcrum for the lever pole. In this way quite a purchase can be obtained, and if the rut is not too deep and the car not too heavy so that the rope will not break the car can often be withdrawn.

Flooded Carbureter Due to Punctured Float

Editor The Automobile:

[2,771]—After giving long and faithful service my carbureter has suddenly gone wrong. A steady stream of gasoline passes into the carbureter and if the drain valve is opened will flow from that. It refuses to work altogether and my car is useless to me until I repair it. Will you kindly tell me what the cause of my trouble would be liable to be and how to go about repairing the damage. R. T. Corry.

Kingston, N. Y.

Examine the needle valve and see if it needs grinding down or if it has a particle of dirt (which has been taken in with the gasoline) stuck in the valve in such a position that it does not work properly. If this is not the case it will be found that the float is punctured and has filled with gasoline so that it has lost its buoyancy. Remove the float and shake it so as to detect if the gasoline has found its way in. If it has the problem of removing it will confront the operator. There are two ways of going about this. One way is to boil the float until all the gasoline therein has been vaporized and has found its way out. Another is to puncture it with another pinhole and blow it out. After the gasoline has been removed the float may be repaired with a drop of solder.

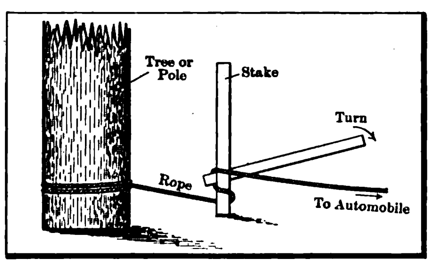

Fig. 1—Showing a handy way of withdrawing a car from a rut with materials gathered on the scene and a length of rope

Changing from Planetary to Selective Gear Is a Costly Undertaking

Editor The Automobile:

[2,772]—I have a 1909 16-horsepower toy tonneau. Would you be kind enough to give me some information telling me how I can install a selective sliding-gear transmission in place of the present planetary type, and also where I could purchase one that would suit my car? Could this car be rebuilt into a roadster type with a seat on the rear? LeRoy E. Warren.

Princeton, N. J.

You should not have any difficulty in turning the toy tonneau into a roadster in the manner you suggest, but the expense of installing a selective transmission will be prohibitive, the operation costing a good deal more than the new car. If you desire to have the work carried out, however, it would be well to consult some first-class repairman, who would no doubt give you an estimate.

One Key as Strong as Two

Editor The Automobile:

[2,773]—Would you kindly tell me through your columns if there is any definite law in regard to the size of key-ways and if I should put two keys in a shaft would it not be stronger than one? I would greatly appreciate any information on this subject which you may be able to give me. I would also like to know the proper size key-way to use on a solid shaft 1 1-4 inches in diameter.

C. H. Butler.

Des Moines, Ia.

The size of the keyway is governed by a mathematical quantity known as the moment of inertia. Taking a section through the key-way as shown in Fig. 2, the relation of the key to the shaft will be seen. The moment of inertia of the cross sectional area of the key about the diameter of the shaft must be equal to the moment of inertia of the section of the shaft about the same axis. One key is as strong as two as long as this equation holds true. If there are more keyways than necessary the shaft will be weakened, since unnecessary material has been cut away. A 1 1-4-inch shaft requires a key in which W equals 3-16 of an inch, D equals 3-32 of an inch and R equals .04 referring to cut.

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their automobile troubles, stating them briefly, on one side of the paper only, giving as clear a diagnosis as possible in each case, and a sketch, even though it may be rough, for the purpose of aiding the Editor to understand the nature of the difficulty. Each letter will be answered in these columns in the order of its receipt. The name and address of the subscriber must be given, as evidence of good faith.

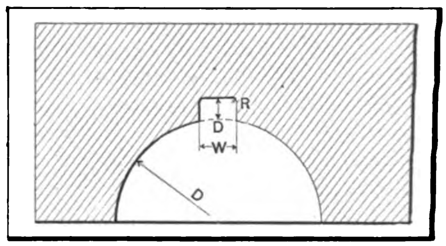

Fig 2—Illustrating position of keyway. D, diameter of hole; W, width of keyway; R, radius of curvature, and D, depth of keyway

Perhaps Some Reader Can Give the Information

Editor The Automobile:

[2,774]—Would you be so kind as to tell us who makes the rubber guard on the inside clincher tire to protect the valve stem from blowouts? It was patented April 9, 1904. The one we have is marked "2 E for 2 1-2, 3 and 3 1-2 inch rims only, No. 17." Any information would be appreciated. L. & J. A. Steward.

Rutland, Vt.

Wants to Cut Oil Grooves in Connecting Rod Brass

Editor The Automobile:

[2,775]—I have noticed that on the newer models of the same make of car as the one I am driving the makers have connecting rod brasses which are slotted so as to have oil channels. What are the purposes of these oil channels? Are they of any ad-

What Some Subscribers Want to Know

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their personal experiences for publication in these columns for the worthy purpose of aiding brother automobilists who may be in need of just the information that this process will afford. Communications should be brief, on one side of the paper only, and clearly put, including a rough sketch when it is possible to do so, and the name and address of the writer should be given as evidence of good faith.

vantage? If they are I would greatly appreciate any information you could give me on how to go about cutting these grooves.

Hartford, Conn. E. F. G.

The purpose of the oil grooves in the connecting rod brass is to secure a more

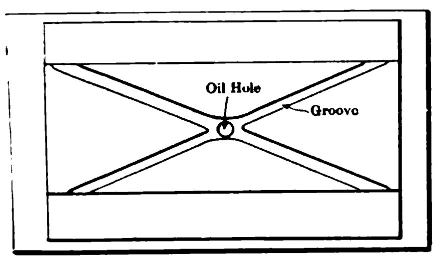

Fig. 3—Showing method of cutting oil grooves in connecting rod brass, grooves and oil hole being indicated

even distribution of oil than would be given by the oil hole generally placed in the bearing. The accompanying illustration, Fig. 3, will give an idea as to how these grooves should be placed. They are cut diagonally with a chisel and hammer, great care being taken not to raise a burr on the surface of the bearing. After having been cut in approximately with a hollow-edge chisel the groove is filed and finished with emery. The depth of the groove should be about 1-32 of an inch and should taper in depth to nothing at the point where the groove ends. The best method is to cut two diagonal grooves as shown in the cut, allowing them to intersect at the central oil hole.

Does the Cut-out Assist the Motor at Low Speeds?

Editor THE AUTOMOBILE:

[2,776]—Will you kindly answer, through the columns of THE AUTOMOBILE, a question which may be of interest to others besides the writer and I am sure will be appreciated if it helps to remedy the abuse of the muffler cut-out.

I notice that some drivers open the cut-out on every slight grade, even in a built-up portion of the city, much to the annoyance of residents of the street. Can you give me any definite information as to the increase of power obtained by opening the cut-out? From my experience in driving a car I believe that, with a properly designed muffler and driving at ordinary road speeds, say 500 to 800 revolutions per minute (with my car this means 15 to 25 miles per hour), there is practically none. H. J. FOSTER.

Scranton, Pa.

The advantage gained by opening the muffler cut-out at the speeds you mention will not result in any appreciable gain in power; consequently, there is little utility in using it. The practice of opening the cut-out in cities or villages is one that should be put down with a strong hand by the authorities, as it brings motorists, as a class, into bad repute with the general public, and the whole body has to suffer for the sins against common decency committed by a few. Some people use the cut-out as a warning signal and this practice should be also stopped, since there are other equally effective and less objectionable signals in existence.

Relative Positions of Armature to Connecting Rod

Editor THE AUTOMOBILE:

[2,777]—As a subscriber to your magazine I take the liberty of asking some information on the correct relative armature positions when compared to the positions of the connecting rod and timer for different positions of the spark. That is, for a retarded or advanced spark. Can you enlighten me? M. F. B.

Atlanta, Ga.

The relative positions of the piston and connecting rod to the armature and the contact-breaker can best be shown by means of a diagram. Such a diagram is given in Fig. 4. The direction of rotation is clockwise, and the maximum spark advance and retardation has been taken as 30 degrees. The position of the armature is so designed that the maximum current will be obtained under the greatest number of conditions of spark advance or retardation.

Understands Everything Except the Reverse

Editor THE AUTOMOBILE:

[2,778]—In a recent issue of THE AUTOMOBILE there was explained to some extent the workings of a planetary transmission, which was perfectly clear to me except that it did not tell just how the reverse gear worked.

Could you kindly explain, either by letter or through the columns of THE AUTOMOBILE, the action of the reverse gear? What I would like to know is just why and how the reverse gear works, as the rest of the transmission is clear and easy to understand. P. F. MINORK.

Overbrook, Pa.

Generally, in reversing a planetary transmission, one of the gearcases is held by a constriction band. This will give a reverse motion to the annular gearing in the casing and hence drive the car in a reverse direction.

Meeting Recurring Troubles

Presenting a Series of the Most Probable Cases

A series of correlated short stories, accompanied by diagrams and characteristic illustrations, including the nature of the troubles that are most likely to happen to automobiles, discussing their causes and effects, all for the purpose of arriving at a remedy. It is the aim for the most part to show how these troubles may be permanently remedied, and as a secondary enterprise it is indicated how the automobilist can make a temporary repair, thereby enabling him to defer the making of a permanent repair until a convenient time arrives.

Keep The Garage from Burning.—Three or four racks full of fire extinguishers and hand grenades may be a most excellent equipment after the garage has started to add itself to the list of local conflagrations; but in this, as well as in most cases of the kind, an ounce of prevention is worth ten tons of cure. A small box of waste may go a long way toward being the proverbial ounce of prevention, and, if it is divided up into two parts like the one shown in the accompanying sketch, Fig. 1, proves, besides, a great boon to the garage owner. One part of the box can be used for soiled waste and the other part for clean.

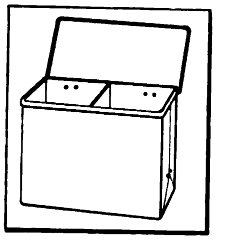

Fig. 1—Waste box divided in two parts to hold soiled and clean waste

A box of this sort may be stowed in a small place and indeed is better if it is kept off the floor at a convenient height, as in this way it will be fastened in one place and will not be kicked to the furthest confines of the building at a time when it does not happen to be required. The box does not have to be heavily built, but should be strong enough to be durable.

While speaking of boxes it may be well to mention the great utility of a series of pans in which to put all the fittings which will no doubt accumulate as time goes on. These pans may be of the type shown in the sketch, Fig. 2, and should be carefully classified with descriptive labels so that they attain the height of their usefulness. In repair work, where small parts need replacing, it will be surprising how many times the required part will be found to be in one of the pans.

Where to Keep the Hose-Rack.—The proper time, of course, to determine the position of the hose-rack is when the garage is being built, for once the water piping has been put into the building, or in some cases left out, it makes a very difficult matter of leading it to the desired place. The hose-rack should be in such a position that the hose can be used to the greatest advantage and therefore the position of the valve should be carefully determined. If the owner has such a place that he can wheel the car out of the garage and wash it down outside, the hose-rack and valve should be placed near the door and not at the rear of the garage. On the other, hand, if the garage is in some place where the washing will have to be done inside, the car may be pushed to the back end of the garage, which should be equipped with adequate draining facilities, and the valve and rack placed so as to be convenient. In Fig. 3 is shown a hose-rack and valve in position and the method of supporting the rack. The hose is kept attached to the valve and the nozzle is always in position, so that the hose is ready for use at any time. The valve and two brackets are placed one above the other so that the hose will run free.

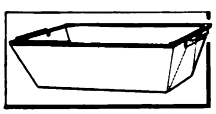

Fig. 2—Type of pan to be used in keeping miscellaneous fittings

It is of no advantage to have a hose longer than will be required, in fact it is a detriment, as all the hose will have to be unwound every time that it is used. Discretion should be used in buying the hose.

A Very Handy Tool.—The adjustable spanner shown in Fig. 4, while a very handy tool, is not found in as general use as its great convenience and flexibility would seem to justify. It is very light and may be used for a variety of purposes. Its shape is such that there will be very few bolts or nuts on the car which will not be in reach with a tool of this nature. If more circumspection were used in the purchase and equipment of the tool kit a great many useless tools could be eliminated and the weight and inconvenience of the equipment cut down. It is generally found in the garage as well as in the machine itself that after a time various instruments of different sorts that were purchased, perhaps, in a moment of misdirected enthusiasm or for some other reason, will collect. If tools of the nature of the adjustable spanner were kept the ever-growing list of impedimenta in the garage would be minimized.

The Thermo-Syphon System.—With this type of cooling the recurring troubles are not very apt to be frequent or serious unless it is a case of gross neglect on the part of the owner or driver of the car. In Summer or Winter the system will perform its work if treated properly without any sign of a balk. The flow of water is entirely automatic and will, as a rule, be found to be very satisfactory if the pipes are sufficiently large. The accompanying cut will give a good diagrammatic idea of the system. In Fig. 5 R_1 is the reservoir, K is the radiator, C_2 the water inlet to the cylinder jacket D_1; C_1 is the water outlet. As the temperature of the water in the cylinder jackets rises the water will commence to rise up into the water outlet pipe at the top. This water will naturally have to be replaced from the water inlet, setting up an automatic circulation which will be the more rapid as the cylinder heats up. The water in this system maintains a well-balanced temperature, well below boiling point.

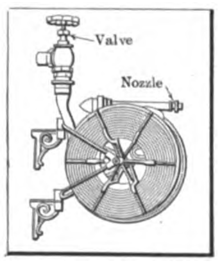

Fig. 3—Showing method of supporting hose-rack with position of valve and nozzle

The Correct Way to Pour Gasoline.—In pouring gasoline from a tank as well as in nearly every thing else there is a correct and an incorrect way to go about it. The correct way is accompanied by cleanliness as well as by speed and neatness. The accompanying cut, Fig. 6, shows the correct and the incorrect method of procedure. The left-hand part of the figure (A) shows the wrong way and the right-hand side (B) the right way. If the gasoline is poured so that the spout is just on a level with the top of the fluid the operator is able to regulate the flow at will, and when the tank is full he can stop immediately without spreading the gasoline over several square inches of unnecessary space. He can pour as rapidly or as showly as he pleases because he can regulate the head of gasoline over the spout to suit himself. While pouring in the incorrect way as shown in the left-hand side of the same cut the spout is at an almost constant distance below the level of the liquid and the gasoline flow can not be regulated to any great extent. When the tank is filled it will be necessary to stop pouring at once and in this case it is very hard to do.

Putting a Lock Nut on Correctly.—The lock nut, as shown in Fig. 7, is generally smaller than the nut whose office it is to hold the bolt to its work. The strains on the lock nut are not very great in any case, and for this reason it does not require so large a bearing surface on the threads. A bolt when brought into place with a powerful wrench compresses the metal which it bears against so that there is always a strain due to the elasticity of the metal, which impels it to regain its original shape. This longitudinal strain on the bolt is all taken up by the threads of the bolt and by the threads of the nut which holds the bolt in place. Since this strain is ever present the jars and vibrations of the machine of which the bolt is a part take the rôle of a hammer which is giving a combination of an outward and lateral blow. The very blow that would be employed if it was desired to remove the nut with a hammer. To overcome this tendency a smaller nut is placed so as to lock the first nut into position.

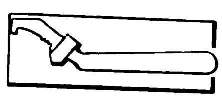

Fig. 4—Type of adjustable spanner which will be found to be a handy tool about the car

When putting the lock nut on the bolt it should not be screwed directly down upon the first nut in the idea that it will stay there and lock it in place, as this is not the case, for the two nuts will then merely act as one large nut and come off together. The method to be pursued is different, beirg to first tighten the nut to be locked as much as possible, the lock nut is then brought down upon it and turned as far as it will go, whereupon the nut first tightened should be slightly turned back so as to bear against the lock nut. This method will set up reactions in metal surrounding the nut which will effectually counteract any tendency the nuts may have to jar off.

Get a Good-Sized Torch.—If you cherish any desires to do soldering work about the garage or, for that matter, at all, you will no doubt invest in some sort of torch in order to carry on the work. There are torches and torches, and the kind usually seen about the average garage are not exceptionally well suited for the work. The form of torch which should be bought will vary, of course, for the different kinds of work expected of it, but for the average garage equipment a torch such as is shown in the illustration, Fig. 8, will be the correct type to buy. For all-around purposes a tool should be designed so that it will be large enough to handle the most arduous duty to which it will be exposed, and it is for this reason that a torch of the design depicted in the accompanying illustration should be purchased when outfitting the garage or repair shop.

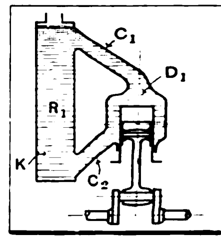

Fig. 5—Diagram of thermo-syphon system. R_1, reservoir. K, radiator. C_1, water outlet. C_2, water inlet. D_1, water jacket.

Initial and Final Temperatures in Gasoline.—An initial temperature of 60° F. will be sufficient for vaporization if the nozzle delivers a true spray. This will give a final mixture temperature which is considerably below the freezing point of water, and will thus cause a drying of the air through a condensation of the water vapor present. With perfect spraying and initial temperatures at 60° F., vaporization is still far from instantaneous, and cannot be completed within the carbureter itself.

A temperature as low as 32° F. would not be attained by the mixture within the carbureter and lower manifold, but would begin to be approximated only toward the upper parts of the manifold. The heat conducted from the cylinders by the passage walls is sufficient to obviate a mixture temperature of 32° F. even during the latter part of the vaporization, which takes place quite close to the cylinders. With initial temperatures at 60°, a temperature of 34.5° F. has been observed in a perfectly vaporized mixture just before its entrance to the valve pocket. This seems to show that the heat of the manifold walls entered into the action toward its latter part, and prevented freezing of water vapor while at the same time assisting vaporization. The engine was running at about 950 feet per minute piston speed at full load.

The lowest initial temperatures are determined by the fineness of fuel division, which is determined by several conditions, as mentioned above. If the division is imperfect, a greater heat supply will be needed in order that the vaporization may be complete within the limited time available, but the greater the heat supply the hotter will be the mixture and the greater the power losses.

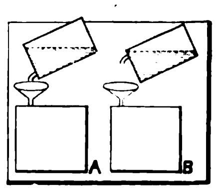

Fig 6—Correct and incorrect ways to pour gasoline. A, incorrect; B, correct.

In the vaporization of fuel in spraying carbureters it is often found that no air temperature up to 120° F. is efficacious in bringing about complete vaporization within the allowable time. Where the fineness of delivery has been progressively increased to a possible maximum value it has been found feasible to form a mixture of perfectly vaporized gasoline and air with an initial temperature of 58 deg. F.

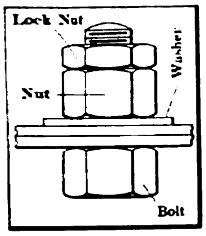

Fig. 7—Showing lock nut in position on bolt

In a typical spraying carbureter the method of application of heat for vaporization for best results will depend upon the character of the fuel spray, as well as upon the construction of the mixing chamber of the carbureter and the form of the manifold passages. If the division at the nozzle is fairly fine, the application of additional heat as an increased initial air temperature will, in general, be of the greater value. This is more particularly true if the carbureter and manifold passages are free from bends. If the passages are tortuous, a heating of the walls will assist vaporization with a less expenditure of heat, and will give an equally good mixture with a lower resultant temperature than will a heated air supply. If the nozzle delivery is very poor as regards division, heated walls will serve best.

The whole question as to which of the two methods is best for any specific case resolves itself into another question—with what is the liquid chiefly in contact after it leaves the nozzle? If the nozzle so divides it that it remains chiefly entrained in the air column, a heating of the air will give the best results; if the division is coarse, the liquid will be spread over the walls, and a heating of the walls will then be the better method, subject to the same condition of proper temperature maintenance. The extent to which fuel division is carried at the nozzle determines the temperature at which the mixture can be formed for any degree of vaporization.

Types of Electric Generators.—The magneto generator, besides being the first type of electric generator in use, is the simplest as well as the cheapest mechanical generator. Since, for the power provided, this machine is the heaviest and most bulky, it is only in use for light work, such as ignition, bell-ringing and other light requirements. As shown in Fig. 9, the magnetic field is permanent, the poles being indicated by the letters N and S, standing for the north and south poles respectively. The magnets are very heavy and large, and it is for this reason that the magneto-machine can not be used in the larger kinds of work for which an electric generator is required. The duty imposed by the electric ignition of an automobile engine, while continuous, is not heavy. The continuity renders battery ignition undesirable on account of the exhaustion of the batteries after a comparatively short time of service, although at first there is no more desirable form of ignition than that obtained from the use of batteries on automobile or motorboat. The magneto meets the requirements of ignition perfectly, as it has the two good features of simplicity and constancy. For this reason it is very reliable, and magneto trouble has been reduced to a minimum. Any ignition trouble is much more liable to be in some other part of the circuit than in the magneto. If anything does go wrong with the magneto it is best that an electrician be allowed to do the repairing.

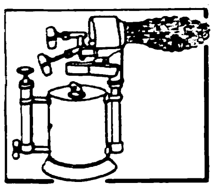

Fig. 8—Illustrating the proper kind of torch to meet the test of average service

The Separately Excited Generator.—The requirements of an electric generator to meet the vicissitudes of larger work than that to which the magneto machine is generally adaptable are met by the separately excited generator. In this type of generator the field magnets are excited by means of a coil fed from some source of electrical energy other than the current from the generator itself. This type of generator possesses all the qualities of the magneto without the disadvantage of the great weight and bulk of the latter relative to the electromotive power produced. It requires, however, a separate source of current for excitation purposes only and it is for this reason that the method is not employed more extensively; as it would require an auxiliary machine or battery, therefore, the system is not used except where there are many machines in action and in cases where the terminal voltage exceeds about 800 volts. The greatest use for this type of electric generator is in exciting the magnetic field of alternating-current generators since a steady magnetic field can not be produced by an alternating current. Fig. 10 gives a diagram of this type.

In this machine as in the magneto the electromotive force may be governed in three ways: By altering the speed of rotation of the armature, by varying the number of conductors by removing some of the brushes, and by changing the magnetic flux through the armature. The latter is done in the case of the magneto machines by shunting the flux away from the armature by means of an auxiliary piece of iron. In the self-exciting generator the magnetic flux is varied by changing the number of turns in the solenoid or exciting coil, or by regulating the strength of the exciting current. Continuous current generators may be made self-exciting by several methods.

The remaining types of generators are shown diagrammatically in Figs. 11, 12 and 13. The series continuous-current generator has the great disadvantage, as it does not start to generate until a certain speed of rotation has been reached that it is also liable to become reversed in polarity. The greatest use of series-wound generators is to supply arc lamps in series. The shunt dynamo sends a small part of the current from the armature through the field winding. When properly designed the machine is self-regulating at mean loads. When overloaded the electromotive force soon reduces itself to zero. The separate-circuit, self-exciting generator supplies the field circuit by part of the armature or by a separate winding on the armature as shown in the illustration. It is much like the separately excited generator.

Latent Heat of Vaporization of Gasoline—The specific heat or amount of heat measured in B.T.U. (British Thermal Units) necessary to raise 1 lb. of gasoline 1° F. is .500. Hence a drop of 1° F. in the temperature of 1 lb. of gasoline corresponds to the dissipation of .5 B.T.U. The specific heat of air at constant pressure is .2375; and a drop of 1° F. is attended by the dissipation of .2375 B.T.U. per lb. of air. Taking the mixture proportions as 1 : 15.39, as above, the heat available per ° F. of drop in the temperature of the mixture is $1 \times .500 + 15.39 \times .2375 = 4.155$ B.T.U.

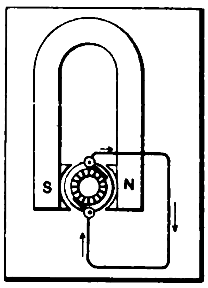

Fig. 9—Diagrammatic representation of a magneto-generator

Since the latent heat of vaporization is very approximately 210.5 B.T.U., it follows that this 210.5 B.T.U. must be supplied by the ingredients or by heat from some outside source applied directly to the fuel.

Consider the heat supply in the mixture ingredients themselves. Since the mixture 1 : 15.39 is capable of supplying 4.155 B.T.U. per ° F. of drop, it will require a drop of $\frac{210.5}{4.155} = 50.66°$ F. in the mixture to completely vaporize the 1 lb. of fuel contained therein. The mixture 1 : 15.39 cannot exist below 1.5° F., so it will be necessary that both the air and the gasoline have a temperature of at least $1.5° + 50.66° = 52.16°$ F. before the commencement of vaporization. If the mixture is 1 : 18, it can exist at —5.8° F., and the initial temperature of the ingredients must be at least 38.3° F.

If the requisite amounts of fuel and air are placed in a vessel insulated from outside heat, the above initial temperature values will hold only when the time allowance for vaporization is unlimited. Compared with the short time in which vaporization must be completed in an automobile engine, the passage of time before vaporization would be completed would be almost infinity. However, there are three methods whereby the rate of vaporization may be accelerated; either the fuel may be introduced in a finely divided form; or the initial temperatures of the mixture may be made higher than the above values; or a combination of both methods may be employed.

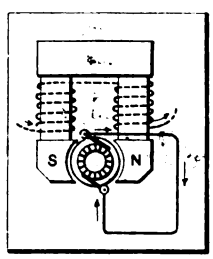

Fig. 10—Showing diagram of a separately excited generator

In any case, the temperature drop can be no more than 45° F. in any mixture of gasoline and air. Therefore, if an increase in initial temperature is resorted to, the final temperature will be higher than that necessary to support the mixture proportions by just the amount that the initial temperature is raised. Suppose an initial temperature of 100° F. and a drop of 45° F. The resulting final temperature in the mixture will be 55° F.

In consideration of the form in which the fuel is presented to the air in the average carbureter, this final temperature will be higher than 55° F. because the total amount of fuel will not have been vaporized, and the amount of heat necessary to complete the vaporization will remain in the mixture as a temperature value. But suppose the vaporization to have been completed in two cases with the final temperature of 55° F. in one and 1.5° F. in the other. Since the same amount of fuel is present, the volumes per lb. of the two mixtures, at the same pressures, may be taken as bearing the same relationship to each other as the volumes per lb. of dry air at equal pressures and the two temperatures given. Thus, the ratio of volumes per lb. of mixture may be expressed 1 : 88, for the two mixture temperatures of 1.5° and 55° F. respectively. Therefore an engine can aspirate only .88 the amount by weight of 55° F. mixture that can be aspirated of the 1.5° F. mixture. Loss in weight of charge will be greater than here indicated, since the efficiency of the pumping strokes will vary with density of the fluid.

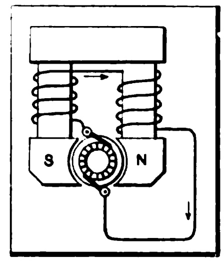

Fig. 11—Illustrating a series-wound continuous-current generator

The power of an engine varies as the weight of charge, being greater with a lower mixture temperature.

Fuel Economy in High Velocities.—The fuel economy resulting from the use of air velocities higher than the average, and thus lower pressures, is quite marked. Of course, with high charge velocities, the maximum power is not realized above a certain piston speed; but the fuel economy and efficiency will be greater within the range which the high velocity device can supply without too great a loss per cylinder charge. This latter fact is easily demonstrated by making two series of runs with any multiple-cylinder automobile engine. One series should be made with carbureter and manifold passages of such areas that an average charge velocity of about 8,000 feet per minute is had at a piston speed of 1,000 feet per minute, and the other series with passages which will give the above charge velocity at between 600 and 700 feet per minute piston speed.

A comparison of the two series of runs will show that up to that piston speed at which the volumetric efficiency of the engine pumping strokes falls off because of too high a charge velocity the power deliveries are approximately equal, the fuel consumption per brake horse power hour and the thermal efficiency have each been improved. The passages giving the above charge velocity at the higher piston speeds will permit of the development of a greater power at those speeds, and are thus superior from the viewpoints of maximum economy and efficiency at maximum output, which is the condition desired.

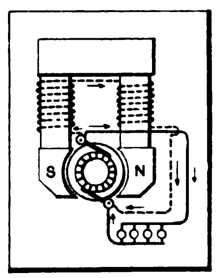

Fig. 12 — Representation of a shunt-wound generator

The points which it is desired to bring out are: That the greater the pressure drop in the passages the more perfect will be the breaking up of the fuel, the more rapid will be the agitation and internal motion in the mixture column, the greater will be the vaporization due to pressure reduction; and, as a final result, the fuel will be more thoroughly vaporized, and the mixture more homogeneous. There are in present practice several examples of the above utilization of high air velocities and low pressure in the carbureter passages. In the best of these the maximum charge velocity in the manifold and past the valves is kept down to the value given above (8,000 ft. per min.); and the high velocities and low pressures are secured in the carbureter passages through several spraying nozzles, each located in a separate, small passage. These are put into communication with the manifold in a progressive manner in accordance with the engine demand; and thus practically constant, high air velocities and low pressures are maintained, no matter how many or how few are serving the engine.

The advantages possessed by such a device for the vaporization of the fuel are apparent, though it appears that these devices were primarily designed with a view to securing a more automatic proportioning of the mixture.

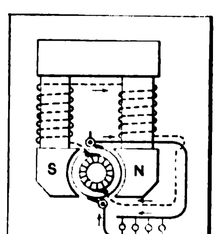

Fig. 13—Diagram of a separate-circuit, self-exciting generator

Modern Automobile Factory Practice

Electric Drive the Trend in the Newer Plants

The problems peculiar to the manufacture of automobiles are met in at least a representative number of large plants by the electrically driven machines which combine the advantages of flexibility and low first cost with that of insurance against heavy financial loss in off years. The product of the General Electric Company is used to illustrate some of the points.

THE manufacture of automobiles on a large scale is conducted under conditions which are peculiar to the automobile industry rather than typical of modern machine shop practice. A large percentage of all the cars purchased are pleasure vehicles, hence they represent the idle capital in the country which is directly dependent upon the prosperity of the times. It is evidently impossible to predict therefore the probable demand for any appreciable time in advance. For this reason the factory apparatus has been designed in a large majority of cases to give the maximum flexibility with a minimum investment. Or the factory must be able to meet the greatest demands which will be laid upon it as well as not to suffer financial loss during an off year.

Where electric drive is used, for the most part, the rates are low for the power used during the ordinary working day, and the consumers are thus saved the large and somewhat risky investment of expensive generating equipment. There are, however, several isolated automobile plants in various parts of the country a small percentage of which are using direct current apparatus, although in general alternating current is employed. This is the most satisfactory source of power, since the factory is able to use polyphase induction motors and to take advantage of the reliable and simple features of construction which are peculiar to these types of motors.

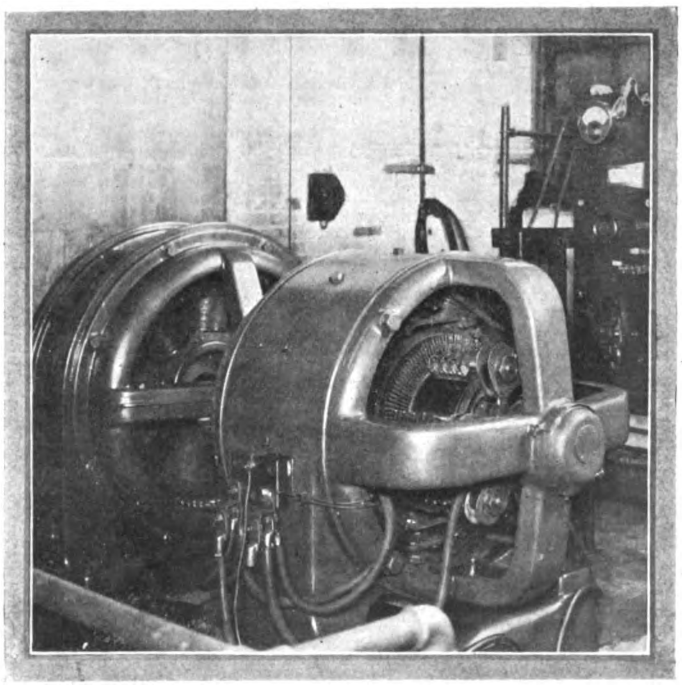

Fig. 1—Synchronous motor generator set consisting of 900-250-volt generator and 900-220-volt synchronous motor

In one of the largest groups of automobile manufacturing buildings in the United States the electric power is supplied from a steam generating station having a capacity of 7,000 kilowatts. The generating units consist of two Curtis turbine alternating current, three-phase, 60-cycle, 5,000-volt generators, one of the vertical and the other of the horizontal type. Energy is transmitted at the generator potential to the plants by an underground conduit system composed of five three-phase lead-covered cables insulated for 24,000 volts, each cable having a normal capacity of 2,500 kilowatts. The conduit system is arranged to receive additional cables as they may be required. In addition to the load imposed by the automobile plant, the power station supplies light to a city of 40,000 population.

The largest plant in this group employs about 9,000 men and turns out 180 complete cars per day. The electrical distributing system of this concern consists of nine step-down transformers for reducing the potentiality of the incoming current from 5,000 volts to the working voltage of the motors and the lighting circuits. The motors are operated from three-phase, 440-volt mains,

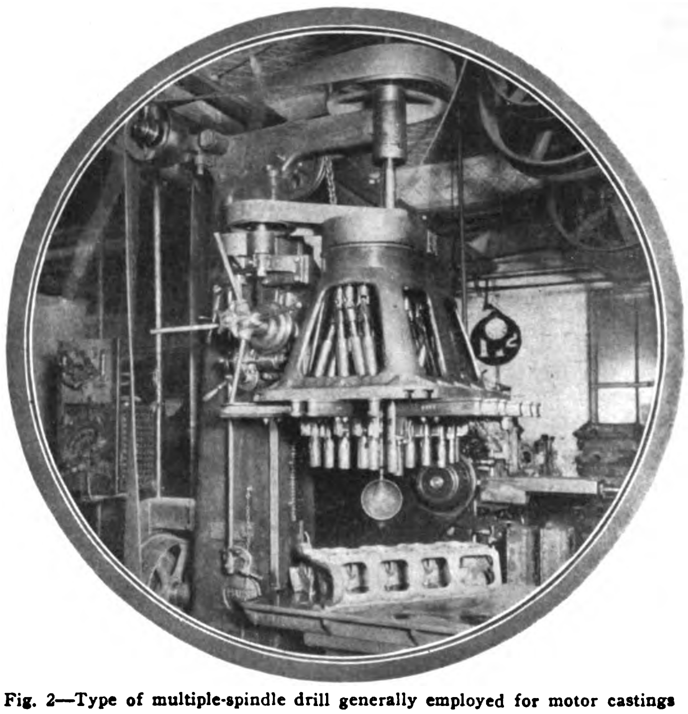

Fig. 2—Type of multiple-spindle drill generally employed for motor castings

while the lighting is supplied from single-phase, three-wire, 110-220-volt mains.

The transformer stations are completely equipped with control and distributing apparatus, including large oil-break switches for high- and low-tension currents, tubular busbars of seamless copper and all protective devices. The transformer capacity totals 6,375 kilowatts for power and 1,650 kilowatts for the lighting circuits. Fifty-two oil-break switches ranging in capacity from 500 to 2,000 amperes are employed. Energy is distributed through the building in iron pipe conduits.

The factory machinery will be found in most cases to be suitable for constant speed drive, and the squirrel-cage type of induction motor will be suitable. In the above-mentioned factory this type of motor was made standard and was mounted in bays in the single-story buildings, while in buildings of more than one story they were suspended from the ceiling. One hundred and eight-five motors ranging in size from 5 to 100 horsepower capacity are installed; the 25, 35 and 50-horsepower sizes predominate, however, and a large number of motors of this size kept on hand enables the electric department to make rapid changes on short notice in case of a breakdown or change in the load requirements. Frequent tests should be made on all the motors so as to keep the load on each as nearly normal as possible.

The sheet metal working departments require large form-presses which will be operated by electric motors of 35 horsepower. In the factory described these motors are mounted in the bay, similar to the manner described for the group drive. The

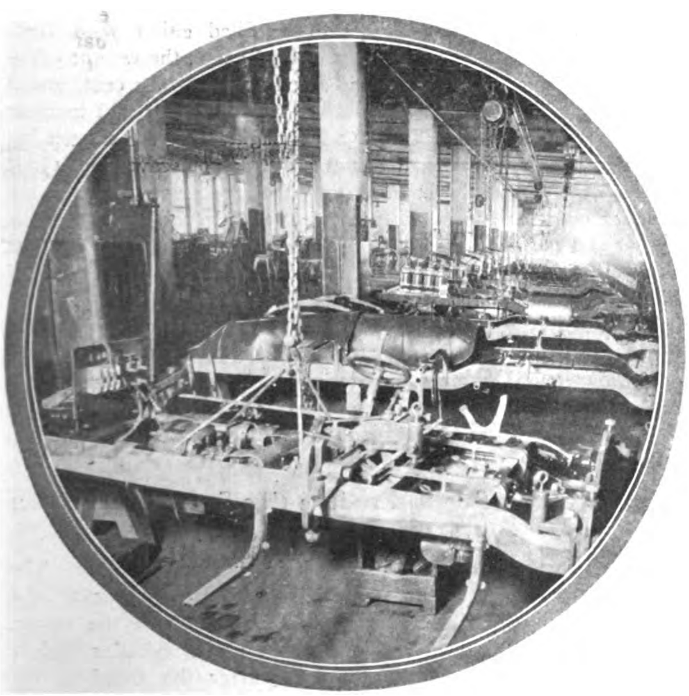

Fig. 3—Milling machine driven by 1-2-horsepower, 1200-220-volt, induction motor

electro-plating department in this factory is equipped with two generating sets supplying current for this purpose. Each of these consists of a 35-horsepower motor driving a 24-kilowatt low-voltage generator by means of a chain belt. Large copper busses carry the current to the electro-plating vats.

In the building of the engine the work is done to the greatest advantage when all of it is concentrated in one building. The machinery required would be all the necessary apparatus for the machining, assembling and preliminary trials on the engines. In the above factory this department is supplied with twenty-two 35-horsepower, three 25-horsepower and five smaller motors, each, in most cases, driving a separate tool, as shown in Fig. 2. In the forging department both steam and electricity are used; steam for some of the larger hammers, while the smaller hammers, shears, presses, blowers and air compressors are operated by electricity. The assembly and body building departments do not require much power equipment, as a large part of the work is of necessity done by hand.

It has been the experience of the larger companies that where a concern could predict accurately the output, they are gradually putting a separate motor on each machine (Figs. 3 and 4). The frames and motors in this case are made interchangeable and several advantages are claimed for this system.

Removing Tight Valve Caps.—When the valve caps stubbornly resist all efforts to remove them from their positions, try running the engines until they are warm and then put cold water in each cap. The cap will contract sufficiently to loosen.

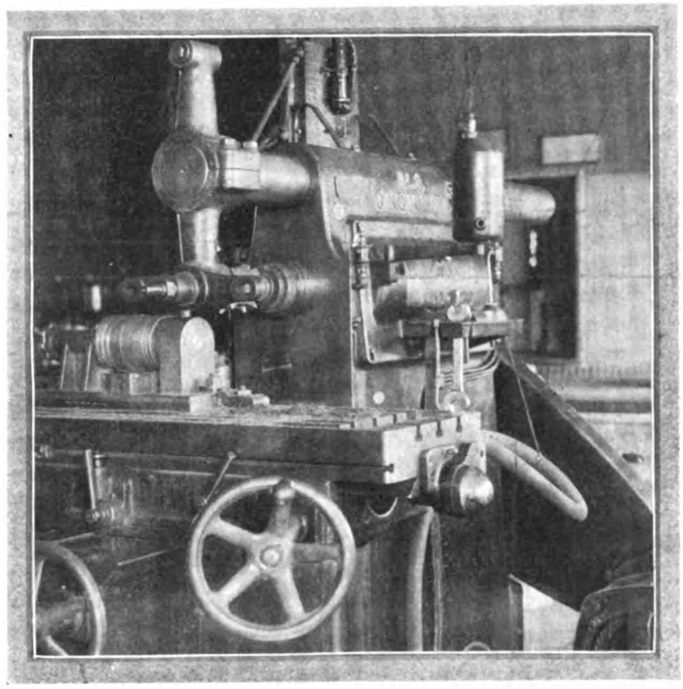

Fig. 4—1-horsepower, 1800-220-volt motor driving portable miller on assembly floor

The Automobile Opens New Territory

Many beautiful but inaccessible spots along the shores of rivers, sound and ocean, as well as in the mountains, which were, until recent years, almost unknown except to an occasional straggler, have now developed into convenient and ideal locations for country homes.

THE automobile has done much in the way of building up outlying districts in the small towns where trolleys are not paying propositions and which have been clustered around the railway station, but it has of late years gone a step further and has been the means of opening up for summer homes, spots where the beauties of nature are unspoiled by frequent traffic. There are many places where the inhabitable sections must be reached from the depot by means of a stage or some sort of rig driven and owned by people who are entirely independent of the livery business as a means of livelihood and therefore not apt to worry very much if a morning call or two are neglected because the horses are needed out in the fields.

The automobile owner is not troubled in this manner and does not have to gauge the distance he lives away from the depot by his sprinting ability when he hears the whistle of the approaching train. Instead he is able to pick out the most favored spot in building his summer home and the real estate will cost him less because he is further from the noisy trains.

Smoke in the Sight Feed—If the glass becomes opaque through the backing up of smoke from the crankcase a good method of prevention is to make a U-bend in the oil pipes at some point in their length where they are horizontal, if possible. This will form what is known by plumbers as a trap, and while making no difference to the flow of oil will effectually check the passage of smoke from the crankcase to the sight feed.

Engine Appears to Lose Power—If an engine appears to lose power without reason apparently, and nothing can be found which is wrong in the working parts of the engine, it may be that the brakes are on when they are supposed to be off. There is a rather inaccessible adjustment on some brake couplings which is likely to work loose, and lengthen the connections so that the brakes may be on at either end of the brake-lever quadrant.

A New Type of Valveless Motor

Describing a Method of Complete Exhaust Scavenging

Two problems that are ever before the minds of designers of internal combustion motors have been combined in one motor by a Belgian named Cottin, and the description of which appeared in La Vie Automobile. The valveless theory part seems to have been well thought out, and the hemispherical shape of the combustion chamber does away with all pocketing.

VALVELESS motors are becoming modish; there is nothing surprising about this, as inventors are working overtime on the subject. Why is it that the janitor, grocer, ironmonger and the doctor rack their brains to invent a valveless motor? Do they really think that it is such a simple matter as giving warning of a protest, weighing 2 cents' worth of mustard or nails, or making their fellow-beings swallow, through publicity, pills specially concocted for pale people?

To obtain perfect running is a problem considerably more complex than the majority of inventors opine.

The most important points to be considered in designing motors in general and valveless in particular are:

1. Lubrication.
2. Gastightness, and
3. Expansion.

These three points are precisely the ones that remain in the background when an endeavor is made to solve the problem on paper.

In describing the Cottin motor a certain peculiarity is presented which raises one of the most interesting problems in the construction of motors.

It Is Possible in the Cottin Motor to Effect a Complete Scavenging of the Burned Gases

It is a well-known fact, that, in the ordinary motor, the compression chamber remains filled at the end of the stroke with dead or burned gases which have a pressure in the neighborhood of the atmospheric.

These dead gases mix with the new gases that are sucked in on the intake stroke. They dilute the fresh gas and heat it. From the thermodynamic point of view they are injurious, as they diminish the weight of the intake charge.

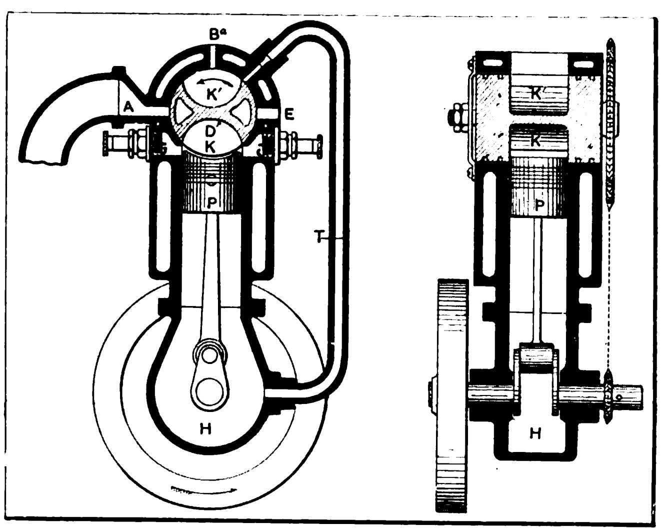

Fig. 1—Sectional views through the Cottin motor, showing the shape of the rotary valve and the method of driving the valve by means of silent chain

In a motor with 5 kilogrammes of cold compression equal to about 70 pounds per square inch, for example, the compression chamber has a volume equal to one-quarter of the piston displacement. If this space were to be filled either with fresh gas or pure air instead of dead or burned gases, the weight of the total cylinder volume will be increased about 25 per cent. and it is to be confidently expected that the motive power will increase in an equal proportion. One would imagine that the scavenging motor will heat less than the motor that is not scavenged. It is a known fact that the calories that find their way through the cylinder walls of the motor are in a large degree occasioned by the burned gases that remain in the cylinder during the exhaust stroke, and in the compression chamber during a great part of the admission stroke.

Take away these heated gases which are in the neighborhood of 300 to 400 degrees Centigrade (570 to 750 Fahrenheit) from the compression chamber and replace them with fresh air of a temperature of about 15 to 20 degrees Centigrade (59 to 68 Fahrenheit) and the heating of the motor will be diminished in a large degree.

How Is It Possible to Produce this Scavenging Effect in a Four-Cycle Motor?

It is a simple matter to produce it in two-cycle motors. The Cottin motor offers a solution and is composed essentially of a cylinder and a distributor situated in the head of the motor. The distributor D shown in Fig. 1 consists of a cylinder slightly conical or spherical rotating at one-quarter the speed of the crankshaft. It is hollowed out in two cells K and K', the chords of which are equal to the bore of the cylinder. As the distributor rotates it covers and uncovers the ports A and E for the intake and exhaust respectively. The cylinder head is a communication with the base chamber of the motor which is hermetically sealed by the pipe T and by the exterior air by the port Bᵃ.

Referring to Fig. 2, the left-hand illustration (A) shows the valve at the end of the suction stroke, the intake port A and the exhaust port E are covered and the piston P on its upward stroke will compress the gas in the concave cell K, but at the same time as the base chamber H in Fig. 1 is hermetically sealed a depression is produced. Pure air sucked in from the exterior enters by the port Bᵃ, filling the cavity K' and will enter by the pipe T into the base chamber.

Again referring to Fig. 2, (B) shows the piston at the top of the compression stroke and the cavity K is placed symmetrically over the piston thereby forming a hemispherical compression space.

The suction of air in the base chamber will have finished by this time and the expansion will commence. (C) shows the piston at the lower dead center, and the expansion is terminated. As the exhaust is about to commence the exhaust port E will be uncovered and the cavity K will be placed in communication with the atmosphere.

Eamining the last phase of the cycle at Fig. 2 (D) will show the piston at the top dead center. The burned gases have been completely displaced from the cylinder, due to the position taken by the distributor which exactly fills the cavity formed by the head of the piston. At this moment the piston commences to descend and the cavity K' places the cylinder in communication with the carbureter and the intake stroke commences. At the same time the piston compresses the fresh air previously taken in to the base chamber by the port B^a and the cavity K'. The cavity K remains in communication with the atmosphere through the exhaust port E, and the air compressed in the base chamber finding an exit by the pipe T, and the port B^a placed about 45 degrees from E ejects through the orifice E the burned gases that remain in the cavity K after being expelled from the cylinder. This expulsion takes place after the time when the piston will have descended to the lower dead center. By that time one of the sides of the cavity K will obstruct the exhaust port E and the other side will open B^a as was shown in the first position of the piston when this latter rises, sucking pure air, but this time by the cavity K.

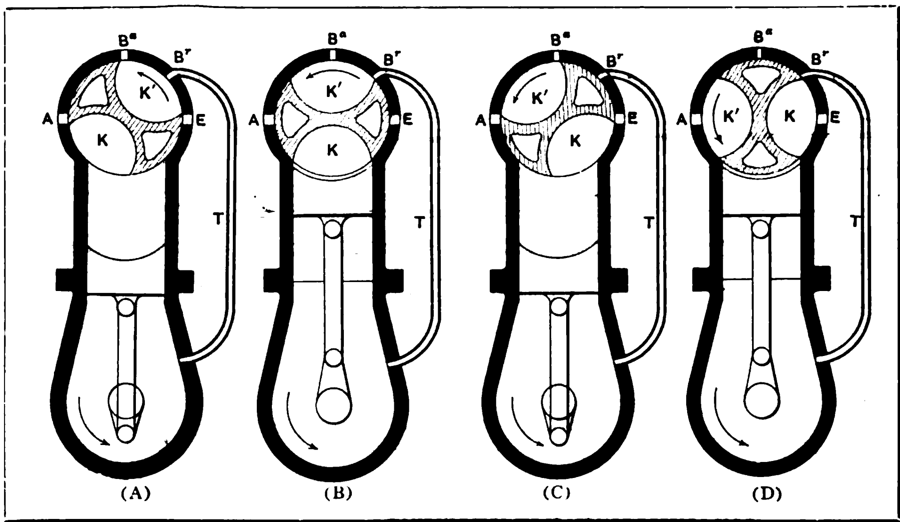

Fig. 2—A, the position of the valve at the end of the induction stroke; B, position of the valve at the end of the compression stroke; C, position of the valve at the end of the expansion stroke with the port E about to be uncovered; D, exhaust stroke having been completed the valve is about to open the port A

It should be noticed that when the distributor takes the position as shown at (B) and (C) in Fig. 2 the piston has compressed and allowed the gas in the crankcase to expand, the orifice B^r being covered. One could profit by this to place in the pipe T a valve or distributor and compress the air in a reservoir which could be used for automatically starting the motor, pumping the tires, working sound signals or brake application, thereby saving the installation of a pump specially designed for these purposes.

This description of the workings of a motor scavenging the burnt gases only takes into consideration the base chamber of the motor itself as an air compressor, but it is clear that it is possible to have a separate compressor outside the motor. In that case there would only be a simple explosion from B^r to E and the port B^a could be suppressed if it were found desirable. In order to obtain a self-starter it would be sufficient in several multi-cylinder motors to open a cock to allow the compressed air to enter in one or several of the cylinders through the cavities of the distributor. It could also be obtained by the movement of the distributor to a certain angle. It would be necessary to give some advance to the valve in practice to take care of the lag in opening.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

WHEN the makers of automobiles promise to deliver a certain number of cars at a given time and the agencies of the companies are induced to rely upon any such promise, it requires no very great amount of discrimination in reaching the conclusion that the agents will suffer great pecuniary loss unless all such promises are scrupulously kept. How to keep a promise of delivery is a simple matter if the system in vogue in the plant where the cars are made is up to the level of the task. But how many heads of companies fully realize the importance of having a well-worked-out system for routing the work and keeping the parts that compose the cars so completely on the go that they will come out finished on time?

* * *

LOOKING at this matter from another and even more important angle, how about the makers of automobiles who idle away a large part of the construction year in a futile effort, finding when it is too late that the work, at least a large part of it, will have to be done on overtime? Who will say that the work as done at night will be as good as the work that is done in a well-[illegible]shop in the daytime? The sap of profit of [illegible]e is most likely to be wasted at night when [illegible]n this way, and too often the character of [illegible] sinks to a low ebb. This would all be [illegible]vere it possible to bring the man-[illegible]of adopting a shop system.

THERE is still another reason why a good shop system is needed. No company can afford to disappoint its customers. It will be fatal to the reputation of a maker to accept the deposit of a purchaser, promising delivery at a certain date, and fail to keep faith. Not a few users of automobiles have been disappointed in this way. Not one of these disappointed purchasers will have a good word for the maker who is at the bottom of the trouble. It is far from good practice to pay large amounts of money for advertising and other sales work of a missionary character, getting "prospectives" into a receptive state of mind, if it is for no better purpose than to arouse their spleen.

* * *

STRANGE as it may seem, there are many difficulties in the path of the engineer who essays to build a good automobile by way of the parts maker. It is not that the parts, when properly made, are not all that they should be; the real difficulty is that the engineer who relies upon the maker of the parts for his source of supply is prone to allow the work to go on to the end without checking up the activities of the maker of the parts. The engineer, if he finds that the parts are not up to his standard, makes the discovery when it is too late to be of any service to him. It is just as necessary to inspect parts that are being made by a maker of parts as it is to keep an eye on the parts that are being made in the home plant. It would be too much to expect that the parts maker could build so much better than the home work that it would be unnecessary to inspect the work. Instantly it is deemed necessary to make inspections, it only remains to say that the best man to do the inspecting is he who guarantees the product to the purchaser, since the risk must fall upon him.

* * *

WHILE it is scarcely to be expected that the world's supply of stupidity will give out this side of the millennium, the fact remains that there is no good reason why railroad companies should hold a monopoly of this atmosphere of the obtusely inclined. Take, for illustration, grade crossings; the idea that it costs too much to eliminate them is a threatening situation to contemplate. If a railroad company cannot see its way clear to eliminate these terrible instruments of destruction, then, the question is, Can the traveling public afford to risk life and limb in its cars; on its roadbed, or in its care? The leading story in THE AUTOMOBILE this week will suffice to show that grade crossings are a menace to the public, nor can it be claimed that it is the automobiling public alone that is doing all of the suffering. But even were it possible to say that only automobilists suffer from this class of neglect, who will care to go on record as advocating that this type of grave danger be continued? That the railroad company is not to be relied upon to cure the disorder is a matter that can be easily proven; for several years the head of one of the railroads in the vicinity of New York has been claiming in public print that it is the automobilist who is at fault! It is admittedly against public policy to electrocute a railroad president every time a citizen is killed by a railroad train, but this is no good ground for claiming that a man should be crushed under a railroad train just because he is the owner of an automobile!

M. C. A.'s Most Important Meeting

Essential Elements of Racing on Trial

First in size and importance among all the meetings that have ever been held by the Manufacturers' Contest Association as far as racing and contests are concerned is the one scheduled to commence to-day at Detroit, which will remain in session over to-morrow. The fate of stock cars as such in competition, of reliability tours, of truck trials and circular-track competition are all to be discussed.

DETROIT, Aug. 9.—Preparations have been made to accommodate fully two-thirds of the representatives of members of the M. C. A. and a list of twenty or more invited guests at the meeting of the General Rules Committee of that organization which will take place to-morrow and Friday in this city. The guests referred to include the members of the Board of Review—the Supreme Court of motordom—and heads and members of the Technical Committee and Contest Board as well as others.

The program of the meeting is the most important ever taken up by the M. C. A. and includes consideration of and action upon the essentials of automobile sport. Among the subjects to be considered are the questions as to the advisability of insisting on strict stock classifications in contests of that variety; as to the advisability of holding reliability tours, and, if so, what kind and how many; whether the rules governing truck contests and trials are adequate and equitable and whether such trials are of service, and as to the holding of sanctioned meetings on ordinary one-mile dirt tracks.

Under each of these four heads there will be a wide discussion and it is quite likely that some radical action may develop as a result of the meeting. Among the general topics that will have attention will be the following: Shall the Contest Board promote any contest? Shall special rules be made or special dispensations granted for any event within thirty days of the start of such contest? What shall be the definition of a "contest"?

If the committee decides to abolish stock car contests, or bars racing on mile tracks, or frowns on truck trials, or decides not to countenance national reliability runs and tours the result will be a radical change in the sporting situation. Such rulings are not looked for by the trade generally, but the mere fact that the M. C. A. is considering them at all is taken as an evidence that the contests in 1911 so far have not proven broadly satisfactory as to volume or results.

Nobody Knows the New York Speed Law

New York courts and police are somewhat mixed as to the proper construction of the speed law as it applies to New York City, if it does at all. In a recent issue of THE AUTOMOBILE the present situation was clearly outlined and forecasted and automobilists were cautioned that the law is uncertain and that the only safe way to proceed is to obey the orders of the traffic squad no matter what they may be.

One magistrate has held that a speed of thirty-miles-an-hour is not illegal if traffic conditions do not make such speed perilous to life and property. Another judge has decided that the old ordinance framed in the days of horse-drawn traffic limiting the speed to 8 miles an hour is still legal and binding. The Police Commissioner has placed the responsibility for construing the law upon his officers individually without defining the law, and all told the situation is exactly as THE AUTOMOBILE described it. Obey the traffic squad and keep out of court.

Chicago Run to Be Eight-Day Affair

CHICAGO, Aug. 7—The Chicago Motor Club to-day decided to make its annual reliability run, set for October, an eight-day tour instead of the usual four days and a route running through five States was adopted. The night stops will be: Indianapolis, 213 miles; French Lick, 190; Louisville, 58; Cincinnati, 170; Columbus, 200; Detroit, 190; Grand Rapids, 190; Chicago, 215, a total of 1,426 miles. The tour is to start October 6 instead of 9 and will extend to Oct. 13 inclusive. The pathfinder will be a Halladay, which will start out immediately after the Elgin road races.

Show Committee to Hold Meeting

Tentative arrangements for holding the next automobile show in Madison Square Garden will be discussed at the meeting of the show committee of the A. B. of T. this week. The plans so far as they have developed contemplate a gigantic exhibition. The full membership of the organization, as it concerns participation in the show, will be known after the next regular meeting of the Executive Committee which is scheduled for September 6. The drawing for space will take place shortly after the meeting.

Sporting Events Are Stirring

Racing and sporting matters are looking up a trifle and the indications now are for a lively season until snow flies. Among the events scheduled for decision in the near future are a hill-climb at Port Jefferson, Sept. 9; a beach meet at Old Orchard; a 200-mile road race at Columbus, O., on Sept. 2 and a tentative road race at Cincinnati on the occasion of the opening of the new Fernbank dam which insures a 9-foot stage of the Ohio river all the year around at Cincinnati. This race is proposed for Sept. 9.

Remy Brassard Changes Hands Again

SCRANTON, PA., Aug. 7—The Remy Grand Prize changed hands again at the race meeting held here to-day on the half-mile track of the Minooka Driving Club. The Blitzen Benz (Burman) defeated the Mercedes (Knipper) in straight heats, both cars and drivers being controlled by the same interests. A program of non-stock events was run off in connection with the big race. The winners turned up in a Buick, Hotchkiss, Ohio, and Buick.

Premier Caravan at San Francisco

SAN FRANCISCO, Aug. 7—The entire Premier caravan consisting of ten touring cars, a pacemaker and a prairie-schooner trundled up the peninsula from San Jose last week and came to anchor beside the Golden Gate. The tourists were met with acclaim and were given a rousing reception. The cars started from Atlantic City and will finish at Los Angeles. Everybody who started is still with the caravan and as enthusiastic as at the time of starting.

GALVESTON, TEXAS, Aug. 3—The first day of the three days' automobile race meet on Galveston beach speedway brought out a crowd of about 20,000 spectators, and the events were carried through with satisfaction and success. The races were held under the auspices of the Galveston Automobile Club and in connection with the annual Cotton Carnival held here. Members of automobile clubs from all over Texas were in attendance.

The beach was in good condition for the races, firm and smooth, with a favorably low tide after 3 o'clock in the afternoon. No accident of any nature occurred to mar the events. The course was laid out in laps of two lengths. For 10-mile races the lap was 5 miles, allowing the drivers to pass in front of the grandstand four times during the race, and for the 20 and 50-mile races the lap was 10 miles.

The fact that an end has been put to automobile racing on circular tracks in Texas gave an added importance and interest to this meet. Automobile men from all over the State came to Galveston in their cars for these races. A party comprising 35 cars, carrying 100 people, came from Dallas, piloted by George W. Baker of that city, president of the Texas State Automobile Association. Two weeks before the meet President Baker made a pathfinding trip over the route, ascertaining the best course and enlisting the interest of automobile owners along the way. From San Antonio about 30 cars came, and from other cities and towns there were enough to bring the total number of visiting cars up to one hundred.

The first day's events consisted of three stock car races and one non-stock, free-for-all race, as shown in the summaries below. In the stock events the first prizes ranged from $100 to $150, and the second prizes from $25 to $50. In the 50-mile, free-for-all race the prizes were $250, $75, and $25.

The feature race of the day was the 50-mile, non-stock race. There were eleven starters in this, with cars from some of the best factories in the country. The race was won by a 50-horsepower National (Zengel). His time was 42:9 1-2. This is the record for this distance on this course. Zengel's real competitors in this race were another National car, driven by Neal McHugh, and an Inter-State driven by Harry Endicott. Zengel took the lead from the start and never lost it, finishing 2 minutes and 48 seconds ahead of the other National car, and 3 minutes and 35 seconds ahead of the Interstate. A Pope-Hartford machine maintained a fourth position in the race from the start to the finish, piloted by Harry Baker.

Class B, Stock Chassis, Division 2-B, 10 Miles

Car	Bore	Stroke	Driver	Time
Ford	3 3-4	4	Albert Hoffman	11:17
Abbott-Detroit	4 1-8	4 1-4	M. J. Roberts	11:24 1-5

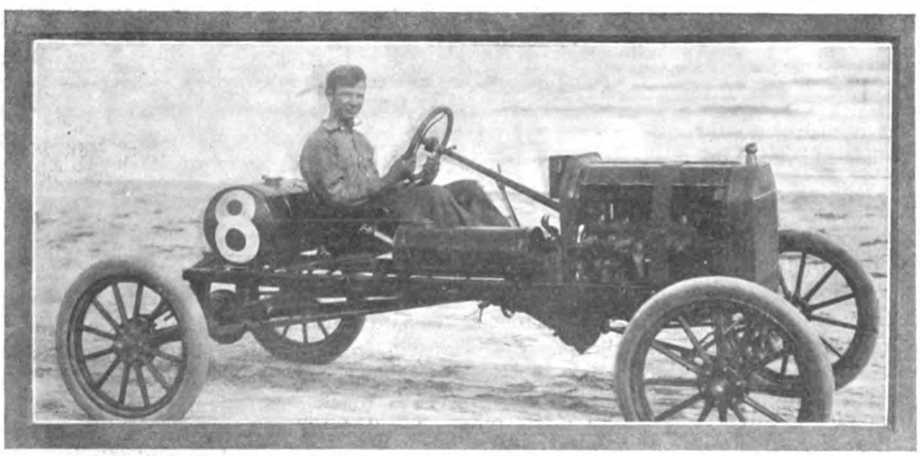
Ford	3 3-4	4	Albert Hoffman	
Marmon	4 1-2	5	Ben Johnson	

Second Day's Races Saw Course Mile Record Broken

GALVESTON, Aug. 4—The principal feature marking the second day of the meet was the fixing of a new record on this course for the mile from a flying start. Len Zengel, driving a high powered, specially built National car No. 12, made a mile in 37 4-5 seconds, or at the rate of 95.23 miles per hour. The previous record, established in 1910, was 40 3-5 seconds. It was made by a Chadwick (Zengel).

The honors of the day went for the most part to National cars. They won both of the non-stock events, as shown in summaries below, and also captured first money in one of the stock races. The stock car which made such a good showing was No. 18 and the non-stock was No. 12.

In event No. 6, a stock race between an Abbott-Detroit and a Ford, the Ford entry was protested on the grounds that the car was too light for the class. No decision was rendered. The summary:



Albert Hoffman in the Ford racer in which he won the 2—B 10-mile race at Galveston Beach

150-mile Race Featured Third Day

GALVESTON, Aug. 5—The big event of the third and last day of the meet was the 150-mile race for non-stock cars. This was won by the special racing National No. 12 (Zengel), making the distance in 2 hours, 6 minutes and 6 seconds. Another National car, stock chassis, driven by W. Rader, came in for second money, finishing the 150 miles in two hours, 10 minutes and 36 seconds. An Interstate special car, driven by Harry Endicott, was third, the time being 2 hours, 44 minutes and 15 seconds. A Ford car finished fourth, time 3 hours and 1 minute, Albert Hoffman driver. The prizes in this race were $750, $250 and $100.

There were 10 starters in this event. A Cadillac car was the only one running when the race was called. It had finished 130 miles. Zengel's National made the first 50 miles in 42 minutes, the 100 miles in 83:04, 120 miles in 100 minutes and the 150 miles in 126:06. The two National cars ran the race without a stop for any purpose.

The Cadillac went the hundred miles, or 10 laps, in 140:46. The Ford went the 100 miles in 122:20. The two were the only cars that ran as much as the 100 miles, except the winners mentioned above. The Jackson and the Abbott-Detroit made 9 laps, or 90 miles. The summary:

Class B, Division 3-B Stock Chassis, 10 Miles

Car	Bore	Stroke	Driver	Time
Cadillac	4 1-2	4 1-2	Geo. De Witt	11:09 2-5
Marion	4	4 1-2	Van Curtis	12-10

Class B, Stock Chassis, Division 4-B, 10 Miles

Car	Bore	Stroke	Driver	Time
National	5	5 11-16	Len Zengel	10:15 4-5
Pope-Hartford	4 3-4	5 1-2	Harry Baker	10:16

Class D, Non-Stock, Free for All, 150 Miles

Car	Bore	Stroke	Driver	Time
National, 12	5	7 1-2	Len Zengel	126:06
National, 18	5	5 11-16	W. Rader	130:36
Interstate	5	6	H. Endicott	164:15
Ford	3 3-4	4	Albert Hoffman	180:01
Cadillac	4 1-2	4 1-2	Geo. De Witt	
Pope-Hartford	4 3-4	5 1-2	Harry Baker	
Jackson	4 7-8	4 3-4	Melun	
Abbott-Detroit	4 1-8	4 1-4	M. J. Roberts	
Marmon	4 1-2	5	Ben Johnson	
Ranier	5	5 1-4	W. P. Hall	

The racing officials for the three days' events were: Racing Committee—Chairman, M. O. Kopperl; J. W. Munn, J. A. Black. Referee—Judge Lewis Fisher. Technical Committee—Chairman, R. W. Carr, G. A. C. Halff, Dr. J. C. Ralston, Captain L. Luth. Starter—S. H. Boren. Assistants—Lee Kempner, G. F. Cotton. Judges—Chairman, G. W. Baker; J. R. Cheek, H. A. Black. Timers—Chief, George Sealy; S. Reinhardt, Dave Burks. Scorers—Chief, Fred Hartel; R. E. McKie, Eli Sanger.

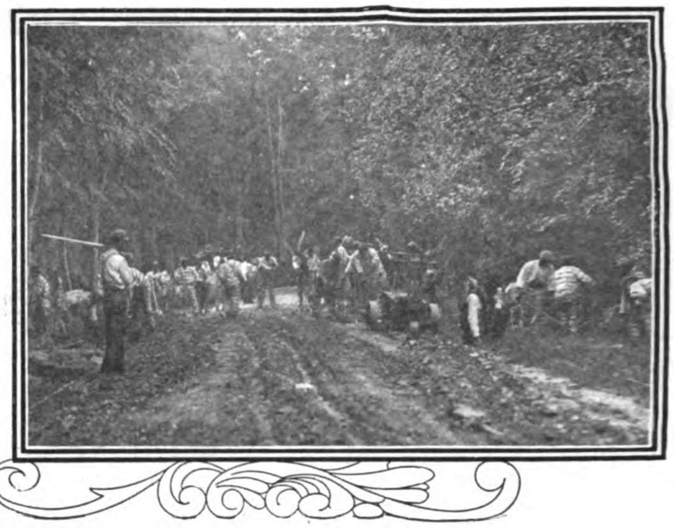
Making the new turn from Norwood Avenue into La Roche Avenue.



Gang of convicts working on the Whitfield Avenue cut-off

Grand Prix Course Under Harrow

Turns Being Cut and Curves Banked

Sixteen weeks before the first of Savannah's quartette of great road races, the course over which they will be run is in process of radical improvement. In two places short cuts will take a few hundred feet from the circuit and the four chief turns, all of which are rectangular, will be high-banked. New road is being built to eliminate the detour at Wylly Island and Whitfield avenue will be practically cut out of the course by the stretch under construction through the forest.

SAVANNAH, GA., Aug. 7—Although the first of the great road races that will be run off at Savannah this fall is still sixteen weeks away, work is being pushed on the course upon which it will be held. The Vanderbilt Cup, scheduled to be run with the Tiedeman Trophy and Savannah Challenge Cup races on November 27, will be followed on Thanksgiving Day by the Grand Prize of the Automobile Club of America. The course which is approximately 17 miles long is being shortened a trifle and vastly improved on the turns.

Big gangs of involuntary servitors are laboring with road-making machinery to shape the course accomplish some important improvements. Starting from the grandstands just after the turn has been made into Waters Road from Dale avenue, the 1911 course will follow Waters Road just as it did last year to its junction with the Montgomery Cross Road. Here there is a 90 degree turn which was not banked high last year. This Fall the turn will be banked so that contestants will not have to shut down to take it. From there is a 1,500-foot stretch of roadway on Montgomery Cross Road to the junction with Whitfield avenue. The right turn will be banked and instead of following Whitfield avenue to the crossing of the Montgomery Road, a new course is being cut through the woods several hundred feet inside of Whitfield avenue and the bad turn that formerly marked the point of emergence into Montgomery Road has been modified by eliminating the curve. From there to the extreme end of the hairpin turn into Ferguson avenue the course is the same as last year, but at the turn a heavy embankment is being raised just beyond the bridge which affords passageway into the infield.

No changes will be made in the long fine stretch of roadway afforded by Ferguson avenue until the course reaches the Norwood line, where instead of following down to the edge of Wylly Island and winding through to Laroche avenue, a short cut through the timber is being built which will cut off several hundred feet and eliminate two dangerous turns.

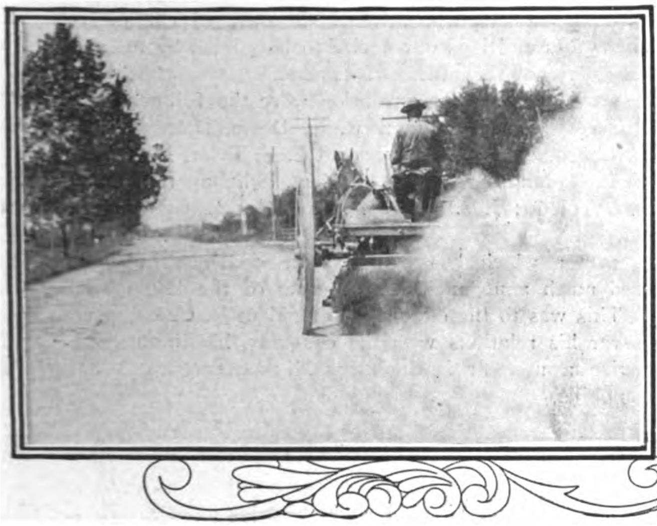
Along Laroche avenue the way will be identical with that followed in 1910 to the turn into Dale avenue. This will be banked and made easier and the run to the last turn will be the same. At the turn there will be another stiff embankment to remove a portion of the factor of danger that was so apparent in the final spurt to the wire.

There is an immense amount of enthusiasm for the quartette of races and those in charge of the event make no secret of their confidence of assembling a magnificent field for each event.

The changes and improvements in the course will probably render it about 350 feet shorter than it was in 1910, while the elimination of the curves due to these improvements and the banking of those that remain will probably make the course considerably faster. It is estimated that the average time for the rounds will be in the neighborhood of eleven or twelve seconds faster than before and if the road surfaces are also conscientiously bettered, this time may be improved as much at fifteen seconds. It is predicted that the car that makes the fastest round will lower the time mark of 1910 by possibly twenty seconds, despite the fact that certain miles were turned last year well over the 100-mile-an-hour notch.

The terrific turns which were practically unbanked last year caused most of the tire trouble that was suffered by certain contestants. This was particularly true of the turn from Montgomery Road into Ferguson avenue which was two right angles. The heavy banking on the Ferguson avenue side will probably give many of the cars an opportunity to avoid the terrific strains and wear on their right rear wheels and tires.

There is considerable disappointment expressed locally that the proposed Glidden Tour which is now scheduled to finish at



Before oiling the course it is thoroughly gone over with sweepers

The oiling of the course is being carefully and evenly done

Jacksonville, Fla., was not routed nearer to Savannah or at least delayed to finish toward the middle of November instead of October 25 as announced. By making these changes in route or time or both, the people here believe that the attendance of a large number of Northern automobilists taking part in the tour could have been insured for the big races.

As it is, a determined effort will be made before the start to interest the tourists in the idea of staying in the South until the road races and attending as individuals. There will also be a party of missionaries to greet the tour at Jacksonville and attempt to persuade the contestants to run over to Savannah.

It is reported here that the real reason why the Glidden was not routed through Savannah was that the roads south to Jacksonville have numerous bad spots and that frequent ferriage is required across the streams and bayous that lie between and the obstacle that stands in the way of a later start than the one scheduled is that if the tour starts from New York later than the date agreed upon in October there is a strong likelihood of meeting bad weather in New Jersey and the certainty of encountering disagreeable conditions in the Virginia hills. Work is progressing on the big new hotel and everything is lovely regarding the preliminaries with the exception of the disappointment that is apparent about the Glidden.

Dead Horse Climb Next

Most important of its kind in the East this season, the coming meeting on Dead Horse Hill under the auspices of the Worcester Automobile Club promises to outshine anything of the kind ever held on the course. A series of stock car events will be a feature of the occasion. The climb will take place Saturday, August 12. Something over sixty entries have been offered by factories, dealers and individuals although several have not been accepted.

WORCESTER, MASS., Aug. 7—Easily the leading event of its kind this season in the East will be the annual climb of Dead Horse Hill near this city which will be staged by the Worcester Automobile Club, Saturday, Aug. 12. The management promises with good weather to have a record-breaking crowd in attendance and the field of entries is by far the largest and most representative that has ever been gathered together for a hill climb over this course.

It is predicted that the record of the hill will be lowered in competition and that new marks in the various stock classes will be made. For the first time this year in the East there will be a series of stock car events under formal supervision. Such events if carefully conducted as to preliminary examinations are intended as ocular proof of the hill-climbing ability of actual stock models and as such are of considerable importance to the public.

Besides the stock car races there will be a spectacular program of free-for-all events for the special speed creations and, as these usually develop some thrilling situations, the prospects for a meeting of sustained interest are excellent.

In the past a special point has always been made of keeping the public informed of the progress of each race and this year the preparations along that line are even more comprehensive than heretofore. The timing will be done by an electrical machine which belongs to the Worcester Polytechnic Institute and will be handled by Professor David L. Gallup, head of the department of Gas Engineering of the institution.

It is a device with a drum upon which paper is rolled and is driven at constant speed by a motor. The tripping of a wire at the start causes a dot to be made on the roll and when the car passes over the wire at the finish another dot is made. The paper tape will be marked with the event number and car number before the start and will be filed as the official record. Along the course a series of electric gongs have been established which will sound from the instant the starting wire is crossed until the car opens the circuit at the finish by tripping the snap switch. The usual telephone system connecting start with finish and various parts of the hill will be used.

Dead Horse Hill is exactly one mile long and the grade rises 325 feet between the starting and finishing points. Crossing the line there is a dip, followed by a level stretch for about 300 feet, passing over a small bridge. From there a sharp rise averaging 10.3 per cent. begins. This grades off into a gentler slope of 8.3 per cent. to the end of the first quarter. From the quarter pole to the halfway distance the grade is considerably sharper, reaching 12.2 per cent. on an average for over one furlong. The third quarter is a series of jumps with one level shelf 150 feet long. The last quarter is very stiff, in one spot being over 20 per cent. The finishing line is just over the top of the hill.

A. D. Converse will act as referee; H. W. Knights, starter; Prof. David L. Gallup, timer; Frank L. Coes, scorer, and Charles F. Webb, clerk of course. Daniel F. Gay is the moving spirit of the contest committee and is associated with Daniel P. Coughlin and others in arranging the preliminaries.

Hughes Makes Explanation

According to Hughie Hughes, who drives a Mercer racing automobile, the only trouble that he experienced at the recent race meeting at Point Breeze was but sufficient to render a stop necessary after two tires had blown, in order to prevent running on the rims.

Detroit Plants to Increase Yield

DETROIT, Aug. 7—Immensely increased 1912 production by the Studebaker Corporation and the United Motors Co., two of the most powerful manufacturing combinations of the industry, were announced here during the past few days.

The Studebaker Co., in its 1912 announcement, states that it plans to build at the E-M-F factories in Detroit a total of 50,000 cars—20,000 of the E-M-F "30" type, and 30,000 of the Flanders "20." This is, of course, in addition to the Flanders Electrics which are being put out at the Pontiac plant of the Flanders Manufacturing Co., but which will, it is believed, be marketed to a great extent through the same dealers.

The 1912 E-M-F "30" will have a lengthened wheelbase—112 inches—and will be put out only in fore-door style, aside from the coupé. Further improvement in finish and the addition of minor details constitute the only other innovations. The three-speed Flanders "20" is now coming through the factory at a rate of 100 a day and the concern hopes to double this speed with the completion of additional factory space, now under construction. The company's announcement states that its advertising campaign has been purposely held back for a month, on account of the complaint of its dealers whom the factory has been unable to supply with enough cars to fill the demand.

The United States Motors announcement was of an informal character and came to light as part of the proceedings at the annual meeting of the central district branch managers of the company, who gathered in Detroit at the call of District-Manager Alex. I. McLeod.

Addresses were delivered at various times by Benjamin Briscoe, president of the company, and Horace De Lisser, vice-president, as well as by Alfred Reeves, Fred Dayton, D. C. Fenner, J. J. Aldrich, C. M. Rodgers and T. L. Marshall, all officers of the various divisions of the company.

The production announcement was made by President Briscoe himself. He promised the branch managers an output of 30,000 motor cars and trucks for the coming season, adding that this figure for the Maxwell, Brush, Columbia, Stoddard-Dayton and Alden Sampson plants had been determined on, as the result of long and systematic correspondence with the company's dealers, who, by estimating the sales for their respective territory, indicated their belief that 30,000 cars would be required to supply the demand.

"Our engineers and designers," said Mr. Briscoe, "have been wise enough to build all kinds of automobiles that our dealers ask for. The men who sell are the ones who know what the public wants and it is our desire to be guided by their ideas on types as well as their ideas of demand."

In attendance at the convention were the following managers of the respective branches: R. K. Davis, Detroit; M. D. McNab, Chicago; E. E. McClure and C. F. Tyler, Cleveland; F. P. Corbett, Columbus; J. W. Hayden, Indianapolis; W. H. McIntyre, Toledo; J. A. Newby, Newcastle; L. G. Murray, South Bend.

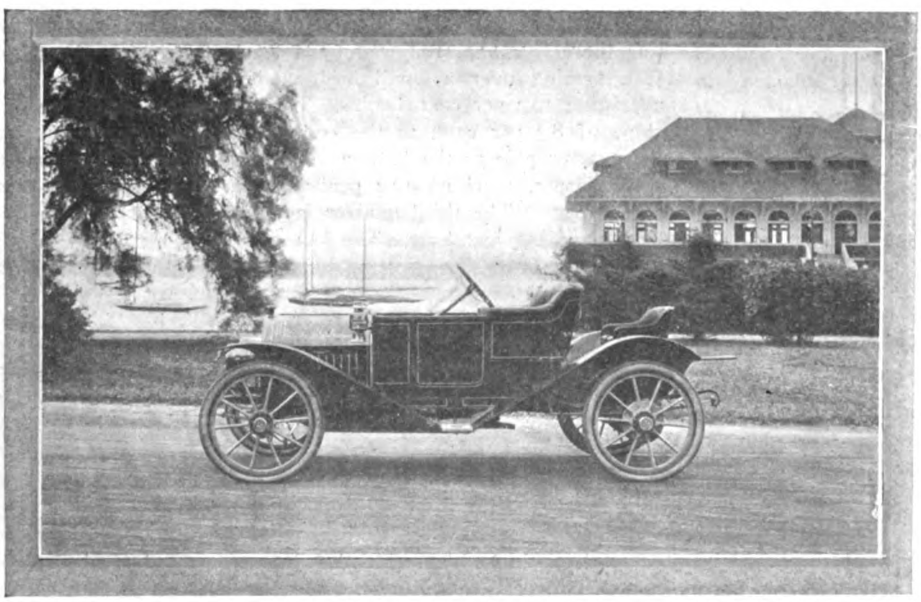
A rumor which has gained some credence in Detroit has caused much annoyance at the offices of the Hupp Motor Car Co. This was to the effect that President R. C. Hupp was soon to sever his relations with the company, his intention being to organize a new firm which would manufacture a competing automobile.

Front of the building of the Freehold Motor-Company, showing entrance to store and garage

This rumor was flatly denied both at the Hupp Motor Car Co. and later by Mr. Hupp himself. Mr. Hupp believes that the report is probably due to the fact that for some time he has been devoting a large share of his energies to the Hupp Corporation—an entirely separate organization from that of the Hupp Motor Car Co., though including a large number of its directors.

"I am interested as much as ever, both financially and in spirit, with the success of the Hupp Motor Car Co.," said Mr. Hupp. "But I regard its affairs as now on a basis which requires very little attention from me. It is an assured success. So is the Hupp Corporation, but it is as yet in a formative stage and I can do more good there, I believe. Please deny for me that I am considering any withdrawal from the automobile company, much less the organization of a competing concern."

Quite a number of Detroit-built motor trucks and wagons have been shipped to Chicago to enter the endurance run of the American, the Chicago Automobile Club and the Wolverine Automobile Club. Several of the trucks have been sent overland. The latest comer went that way. It is the Poss, a four-cylinder, 25-horsepower machine of 1,200 pounds capacity. The company was but recently formed and is backed by Frank R. Poss, vice-president of the Detroit Baseball Club. The start of the car for Chicago was made the occasion of a formal farewell, a champagne bottle being broken over the radiator by Sales Manager Joseph M. Ness.

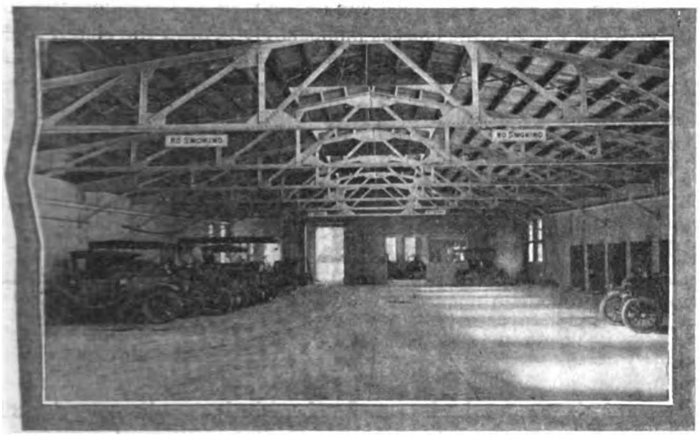


Model 25 1912 Herreshoff fore-door runabout with rumble seat

The Wolverine Automobile Club celebrated "Orphans Day" here Friday and nearly 100 cars were placed at the disposal of the committee. The asylums were all visited and full loads of children were taken on a trip, the itinerary of which included the beautiful residences of the summer colony at Grosse Pointe, and the circuit of Belle Isle.

Carbureter Makers Offer Prizes

CHICAGO, Aug. 7—Manufacturers of accessories are chipping in liberally to the prize fund of the national stock chassis road races, booked for Elgin August 25-26, a total of $3,350 being announced to-day by three concerns which believe the road championships are going to be the greatest motoring events of the year. The Findeisen & Kropf Mfg. Co., of Chicago, maker



Inside the Freehold garage, having an area of almost 7500 square feet; big enough for 80 cars

of Rayfield carbureters, was the first to be heard from with a contribution of $800; then the Bosch Magneto Co. came forward with an offer of $950 and to-day the Stromberg Motor Devices Co., of Chicago, offers $1,600 in cash for the winner.

The Rayfield purse is to go to those winning races in cars equipped with Rayfield carbureters. The winner of the Elgin National is to receive $500 under these conditions and the winners of each of the other three races is to get $100.

The Bosch Magneto Co. gives its $950 provided the Bosch magneto is used. In the Elgin National $200 is offered for a first, $100 for second and $50 for third. In each of the others it is to be $100 for first, $50 for second and $50 for third.

The Stromberg offer is unique in that the carbureter concern offers $200 to the driver in the Elgin National who makes the fastest lap, regardless of whether he uses a Stromberg. In each of the other races $100 is offered for the fastest laps and under the same conditions. In addition the Stromberg will give $500 to the Elgin National winner provided he uses a Stromberg carbureter. In each of the three races the first day $200 is offered for a Stromberg victory.

Military protection was assured to-day when the Elgin Automobile Road Race Association closed with Colonel Milton J. Foreman for the First Illinois Cavalry for Saturday's races, while on the first day the course will be guarded by militia from Aurora, Rockford and Elgin, 250 soldiers having been secured.

Splendid Garage in Freehold

JERSEY, the State of fine roads, is not quite as rich in modern, well-equipped garages, but if the new building used by the Freehold Motor Company, of Freehold, N. J., is indicative of the trend in the automobile business of the State, she will soon be able to boast of a number of fine up-to-date establishments. The building here shown contains the storeroom of the agent for Maxwell and Columbia cars in the Freehold territory, the salesroom being 48 feet wide and 40 feet deep, and containing a nice line of most of the prominent automobile accessories.

The garage proper is 60 feet wide and 124 feet deep and has separate entrance and exit for automobiles. Forty cars may be lined up along the walls in a single row, giving a maximum capacity of eighty automobiles. Gasoline pump and compressed air connections are installed in the storeroom, the gasoline storage tank being located outside the building and the air compressor in the machine room. The latter is equipped with a drill press, lathe, shaper and the other repair tools, in addition to the power plant for illuminating the building.

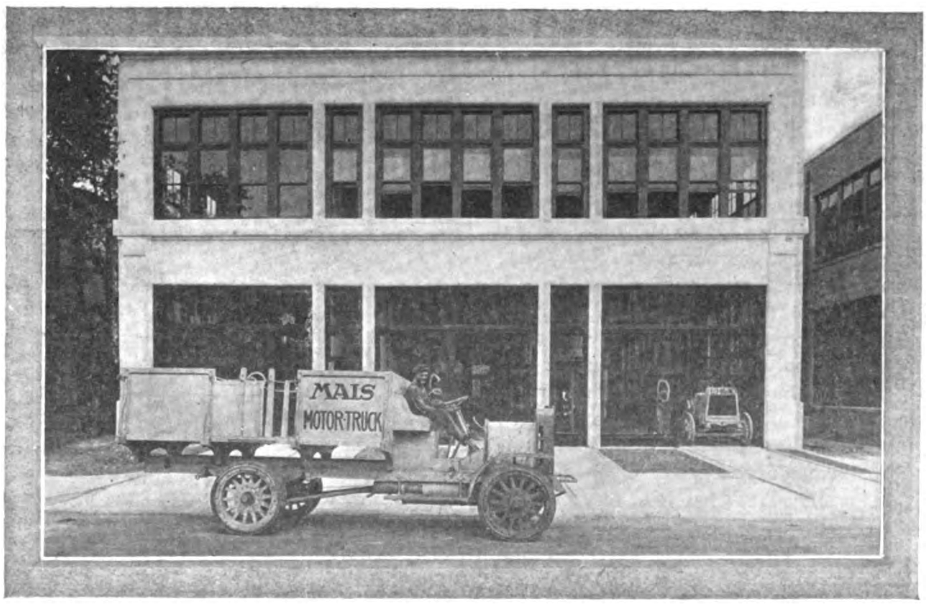
In the garage are a turntable and a traveling hoist, also chemical extinguishers for the case of a fire emergency. The construction of the building is on a fireproof basis throughout. The garage is covered with an extensive skylight, while the front part of the building carries another story, containing a smoking room and parlor.

Frederick D. Bennett is president of the Freehold Motor Company, and William T. Buck holds the position of secretary and treasurer.

Glidden to Be Won by Team Work

Winning the Glidden Trophy this year will be a matter of team work, according to the official announcement of Chairman Butler of the Contest Board. While cash prizes will be given for winners in the various classes, the main prize will go to the team of three cars, touring cars or runabouts or a combination of both, which shall be designated by the name of the town from which the entries come. The smallest total of demerits will win for the team.

The only chance for a technical examination will occur in case of two or more of the teams being tied for the honors. The tour is scheduled to start October 15 and finish at Jacksonville, Fla., October 25.



New 2½-ton Mais truck in front of the fire-proof offices of the company at Indianapolis

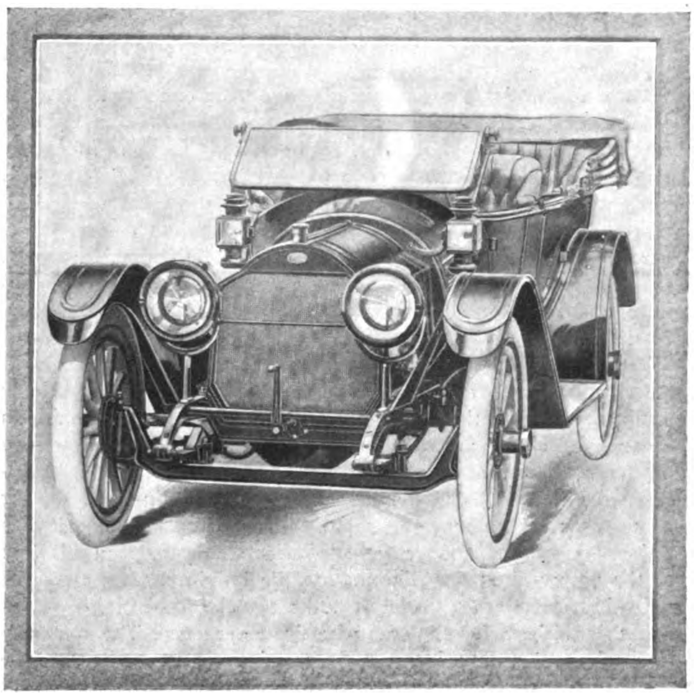


Fig. 1—Front view of the Republic car, showing the general appearance and substantially built front axle

The New Republic Car--an Ohio Product

Built along up-to-date lines, the Republic car, manufactured by the Republic Motor Car Company, of Hamilton, Ohio, is here presented in its current form.

THE motor fitted to the Republic chassis has four vertical cylinders, water-cooled and cast in pairs. The bore is 4 1-2 inches and the stroke 5 inches. The crankshaft is machined from an alloy steel forging and afterward ground and runs on three bearings of large diameter, being offset 3-4 of an inch from the center of the cylinders. The cylinders having T-heads, the valves are consequently situated on either side, and are 2 1-4 inches across the mushroom. The crankcase is made in two halves, the cylinders being bolted to the upper half, while the lower half serves as an oil well.

A Stromberg carbureter is located on the right side of the motor, the lower half being water-jacketed. As may be seen from the plan view illustration of the chassis (Fig. 3), a flexible metal tube carries hot air to the main air intake to assist carburetion. The gasoline tank is located under the driver's seat on the touring car and under the rear seat on the roadster, having a capacity of 18 gallons. A reserve supply of 3 gallons can be turned on from the driver's seat. Two independent ignitions are provided with two sets of spark plugs. A Bosch magneto is fitted on the same side of the motor as the carbureter and driven off the half-time shaft by a supplementary gear enclosed in the front timing gear case of the motor. A Delco high-tension battery system is used, the distributor being located between the cylinders on the same side as the magneto and driven off the intake camshaft by suitable gearing.

Referring to the lubricating system, the oil drains into an oil reservoir, passing through a fine filter, and is then forced to every bearing by means of a gear pump through a sight feed oiler situated on the dash. The crankshaft is bored out to allow the oil to flow to the connecting rod bearings, thereby insuring a constant stream at these points. The cooling is effected by means of a honeycomb radiator placed in front of the motor, the water being caused to circulate around the waterjackets by means of a centrifugal pump driven by gearing off the half-time gears. The clutch is housed in the flywheel, the male member being covered with a leather facing with cork inserts to increase the coefficient of friction. The motor is suspended at four points, the arms resting upon supports that are riveted to the side members of the frame.

Fig. 3 shows the assembly of the propeller shaft and the position of the transmission on the rear axle casing. The control levers are placed in the center of the chassis attached to a cross member of the chassis. The propeller shaft is enclosed in a tube that extends from the forward end of the transmission housing to the cross member of the chassis immediately behind the clutch and is attached thereto by means of a forked joint acting in the capacity of a torque member. In addition two radii rods are fitted, the front ends of which abut on brackets attached to the side members. In this construction only one universal joint is employed.

The transmission is of the selective type giving three forward speeds and one reverse, the shafts running on ball bearings. Direct drive is obtained on third speed and an interlocking device is fitted in order to prevent more than one speed being engaged at the same time.

The rear axle is of the full floating type enclosed in a pressed-steel housing fitted beneath with a tension rod to maintain the alignment of the wheels. Ball bearings are employed throughout and the rear wheels are fitted with large-diameter brake drums on which two sets of brakes operate. External contacting shoes are operated by means of a pedal, while the internal expanding brakes are operated by a lever. It will be seen that the rods are supported on the torque tube and are entirely within the bounds of the chassis frame.

The front axle is an I-beam drop-forging, the pivot pins and knuckles being supported on ball bearings. The cross rods connecting the steering arms are placed behind the axle and the connecting rod is over the axle, thereby being protected from any road obstructions. The front springs are semi-elliptic, 40 inches long and 3 inches wide, and the rear springs are three-quarter elliptic, 45 inches long and the same width as the front. The rear springs are mounted beneath the axle tube by means of drop forgings, thus permitting increased spring clearance.

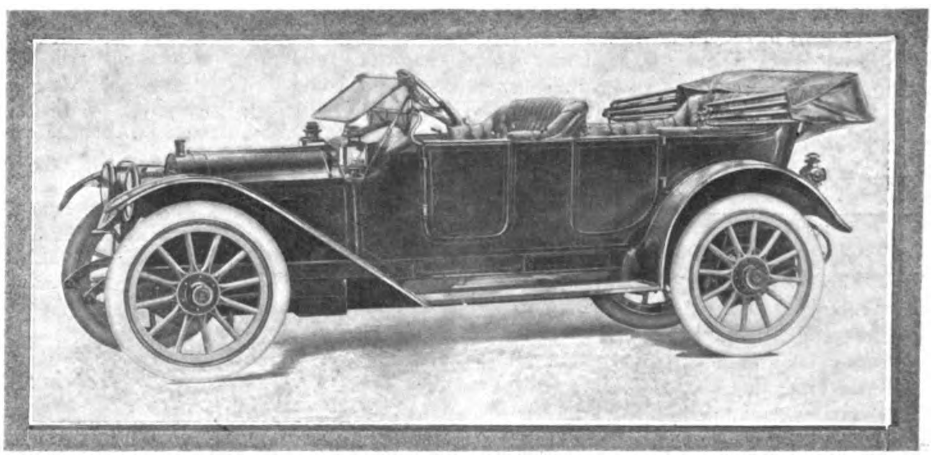

Fig. 2—Side view of the fore-door five-passenger touring body fitted to the Republic chassis

The frame is made of pressed steel of U-section with five cross members, extra angle plates being fitted to the rear for the reception of the half springs. The steering is of the worm and sector type fitted with adjustable thrust bearings; an 18-inch steering wheel is provided. The wheel base of the car is 120 inches, while the tread is 56 inches. Artillery wheels with dished spokes are used and are fitted with 36 x 4-inch tires.

The price of the car with standard equipment is $2,250, which includes top, speedometer, adjustable windshield, five lamps and gas tank. The standard touring car is shown in Figs. 1 and 2 and, as will be seen, sets low and is fitted with fore doors.

New Three-Thousand Pound Wagon on Market

The new model L truck recently brought out by the Chase Motor Truck Co., of Syracuse, has a 30-horsepower motor. The motor is of the two-cycle type, having three cylinders, 4 1-2 inches bore and 5 inches stroke. The motor is air-cooled and is equipped with a Holley carbureter, Bosch magneto and Brown-Lipe sliding gear transmission. The lubricating oil is supplied with the fuel passing through the carbureter into the cylinder, a method which has become common in two-cycle practice. The chassis sills are of selected ash and are 2 inches wide by 5 inches deep. The front wheels are 36 x 3 inches and the rear are 38 x 3 1-2 inches. The wheelbase is 112 inches and the tread 58 inches. The clutch is of the cone variety with cork inserts and the rear wheels are driven by separate chains, being equipped with emergency brake drums. The foot brake for ordinary occasions works on the jackshaft drums.

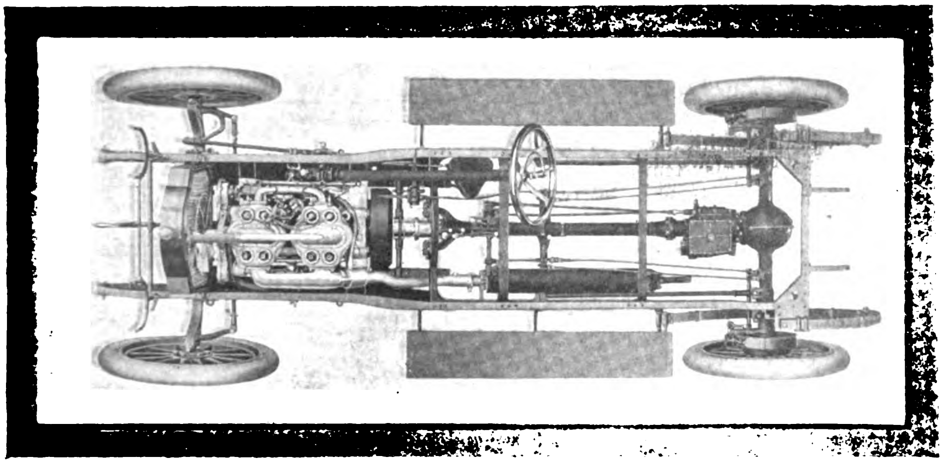

Fig. 3—Plan view of the Republic chassis, showing the general arrangement of the motor and the transmission located on the live rear axle

Simplicity An Objective Point in 1912 Models

The three-ton truck listed as the 1912 model of the Rapid Motor Vehicle Co. of Pontiac, Mich., represents this concern's idea in producing a commercial vehicle which will be as simple and efficient as modern automobile practice will permit. The car has a straight line drive with universal bearings on the ends of the radii rods, which are concentric with the jackshafts and their housings. The engine, which is a four-cylinder, four-cycle vertical, water-cooled type, is controlled by a governor which is sealed at the speed at which the truck is supposed to run when the truck leaves the factory, and, although the setting may be changed, it is so arranged that it cannot be tampered with by a careless driver. The lubrication is by force-feed with separate leads to each cylinder and main bearing, with a return pump for the surplus oil; this precludes the possibility of flooding the cylinder with oil. The ignition is done by Bosch high-tension dual system, which is accessible from the left-hand side of the motor. The radiator is of the flat vertical tube design, of 12-gallon capacity and is suspended on either side by spiral springs which also absorb road shocks.

Commer Truck on Missionary Trip

After having done the baggage carrying of the Chicago Motor Club at the recent Indianapolis races, a trip of 220 miles and covered at 16 miles an hour, the Commer 3 1-2-ton truck has started on a long missionary tour. It is planned to visit the States of Michigan, Indiana, Ohio and New York, making stops at Cincinnati, Dayton, Springfield, Columbus, Toledo, Cleveland, Detroit, Buffalo, Rochester and all the other large cities along the route. At the last report the truck was well on its way towards New York. There is no desire to do this trip in record or limited time, as the main purpose of the trip is to make demonstrations and establish agencies throughout the territories the truck passes through. Probably one of the most beneficial results that will be obtained from this tour will be that derived from the careful daily tabulation of the figures that are being kept of the fuel and oil consumption. Other data is being gathered which should be of great value in many respects, as a road test such as this will bring out any existing weaknesses.

New Electric Vehicle Co.

The Standard Electric Car Co., with its plant at Jackson, Mich., has been recently organized for the production of electric vehicles of medium price. The company announces that there will be no radical departure from standard practice in its designs, but that it will adhere strictly to the current ideas of electric vehicle practice. The car has a four-passenger coupé body, and is operated by means of a chain drive. The batteries used are optional and may be either of the Edison or lead type. The manufacturers are now establishing agencies in different localities and are very optimistic over the outlook during the coming season.

Krueger to Make Electrics

South Bend, Ind., Aug. 7—Clem F. Krueger, for seven years associated with the Studebaker Automobile Company, has been elecated vice-president and general manager of the Standard Electric Car Company, of Jackson, Mich., an organization formed for the production of electric vehicles at a popular price.

One-ton Rapid truck that carries Oakland Motor Car Company's freight between Pontiac and Detroit

The Model X Rutenber Motor

A four-cylinder product of the Western Motor Company of conservative design and used in a large number of cars of various prices. The cylinders are cast separately and the crankshaft rests on five main bearings.

THE Rutenber Model X 1912 motor is a four-cylinder product with cylinders cast separately. The bore of the motor is 4 1-8 inches and the stroke 5 1-4 inches. The inlet and exhaust valves are located on the same side of the motor and are driven off the same camshaft by means of direct push rods R, Fig. 1, operated by a finger L lifted by the cams on the cam shaft C_1. This finger or follower swings on a fulcrum S attached to a removable cover P_1 above the cam shaft; the roller which takes the cam action is in the center and the thrust rod rests on the inside end C_2 of the follower O. This arrangement gives a lift of 3-8 of an inch on both the intake and exhaust valves, which, since the valves are large in diameter, gives an ample clearance for the passage of the gases. The valve stems V are of carbon steel, while the heads are made of nickel steel and the cam shaft C_1 is a drop forging carried on three bearings, being driven off the crank shaft by means of gearing G_1, G_2, G_3, which time the cam shaft down to half the speed of the crank shaft. These gears are located at the front end of the motor and are encased so as to afford them ample protection and lubrication.

The pistons P are long and are provided with five rings, four of which, R_1, R_2, R_3, R_4, are at the top of the piston above the wrist pin, and the other R_5 is located in a plane with the center of the wrist pin. Below the pin there are three oil grooves in the piston which pick up the oil and distribute it over the cylinder walls.

The wrist pin W in Fig. 2 is of hollow section and of such length that its ends clear the piston ring. The connecting rod is attached solid to the pin, thus using the journal of the piston as a bearing, which provides ample surface. Lubrication is taken care of by the oil that finds its way past the ring. The connecting rods are fastened at the wrist pin ends with clamp bolts and held with lock nuts and washers B and N. The connecting rods R are made as long as is compatible with a motor of average height and are provided below the crank pin bearing with a cap S_3, which is a factor in the oiling system of the motor.

The crank case is cast in two parts which are entirely separate from each other. The upper part of the crank case carries the supporting arms of the motor, of which there are four, and besides that it also carries the five main bearings on a series of bridges, the lower part of these being removable and held to the upper parts, which are integrally connected to the upper half of the crank case casting by bolts. There are two of these bolts on the foremost four main bearings and four bolts on the rear main bearing, giving ample protection against vibrations of the flywheel. The lower half of the crank case is an entirely independent member, free from all bearings and gearing and hence may be removed at pleasure without disturbing any of the moving parts of the motor. It is fastened to the upper half of the crank case by means of bolts and when dropped down gives easy access to all the connecting rod and main bearings. The oil reservoir is also located in the lower part of the casting, which is a sort of double-bottomed pan, the lower bottom carrying the oil supply and the upper bottom being a tray which carries the splash troughs. The capacity of the oil reservoir is about two gallons.

The intake and exhaust manifolds are on the same side of the motor and placed one above the other, the lower being the intake manifold. The carbureter is held suspended from the center of the intake manifold and attached thereto by means of bolts to a faced flange. The flanges are also of large size, which tends to produce tightness in the joints. They are held to the motor by means of studs B_4, N_1 and cross bars C_4, making a strong connection.

The motor is water cooled, the jacketing J_1, Fig. 1, running all around the combustion chamber and valve ports J_2. The water

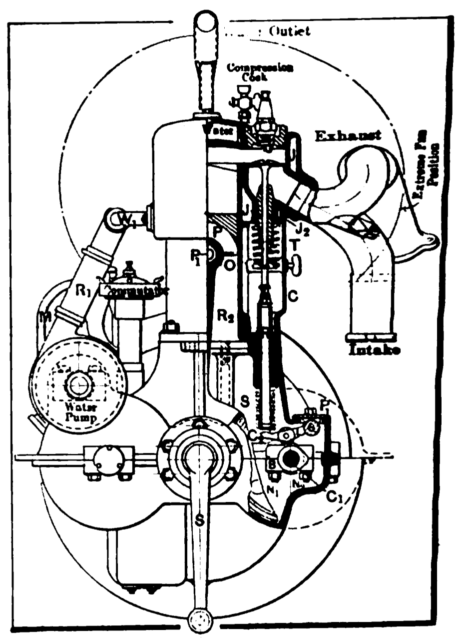

Fig. 1—Transverse section through Rutenber motor, showing details of valve mechanism

pump is of the centrifugal type and driven by intermediary gearing, the extension of the shafts driving the magneto and suitable couplings being used to take care of alignment. The fan is five-bladed and driven off the end of the shaft by means of a belt and pulley. It is held by the adjustable bracket B_1.

The lubrication is a combination of the force-feed and splash system. The oil is taken from the reservoir in the bottom part of the crank case, filtered and forced through leads into the main bearings and splash troughs. The main bearings are thus lubricated by force feed while the remainder of the bearings are lubricated by the oil mist created by the dash of the connecting rod caps into the pools of oil contained in these splash troughs. Since the oil is supplied to the splash troughs much faster than it is used the oil will be constantly overflowing from one trough into the other and from the troughs back into the reservoir, which is equipped with overflow ports to provide for this. The oil is strained as it passes through the system so as to remove any foreign matter which may be accumulated by the oil due to its circulating.

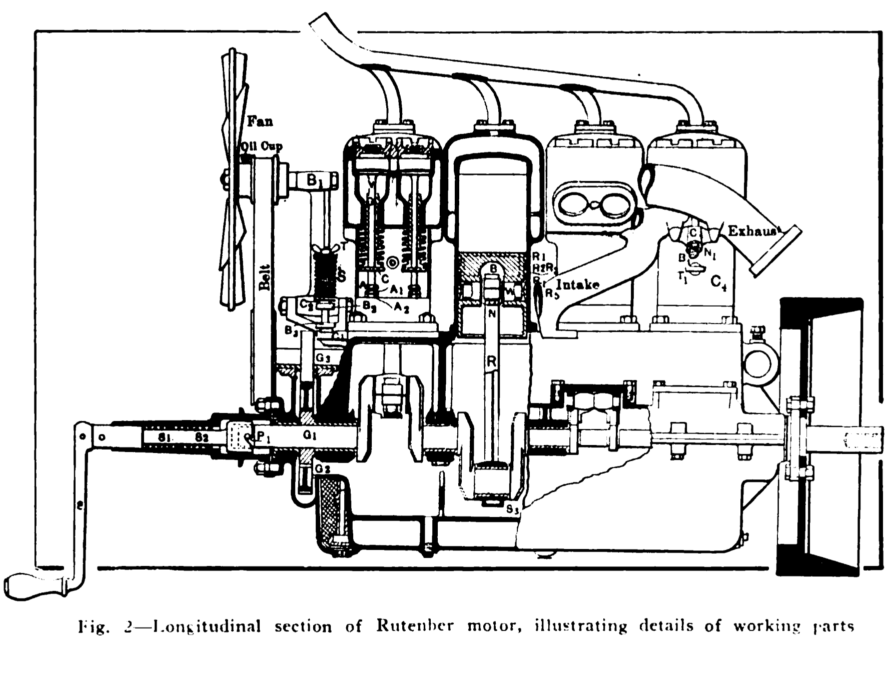

Fig. 2—Longitudinal section of Rutenber motor, illustrating details of working parts

New Things Among the Accessories

License Plate on Front Axle

THERE may be some advantages in the attachment of the front number plate of a car to the axle in preference to the

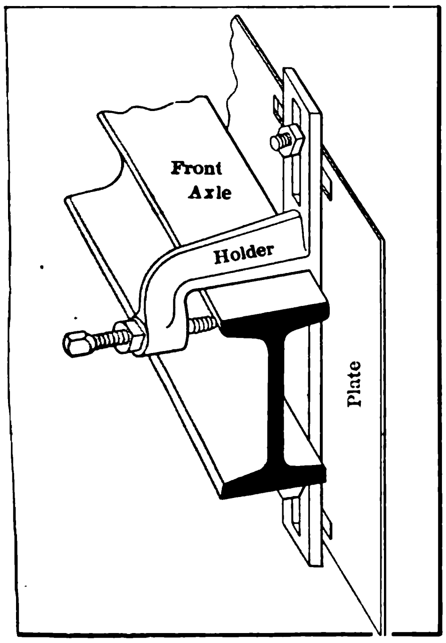

Fig. 1—Showing how the Apco plate holder is attached to the front axle

usual location on the radiator. First, because this latter arrangement covers up part of the valuable radiator surface, thus detracting from its cooling effect; second, because this method of fastening the plate to the car makes it impossible to prevent the plate from rattling, which means not only noise but depreciation as well.

As a departure from plate holders a novel construction, the Apco, is shown in Fig. 1, indicating simplicity and strength at the same time. It is made of bronze, and is fastened to the plate through the four slots by means of screws and nuts, while two bolts serve to press that part of the holder, which bears against the number plate, against the two flanges of the I-section axle. A locknut on the bolt keeps it under pressure for a long time and prevents lost motion to creep in at this place.

The Auto Parts Company, of Providence, R. I., furnish the holder, together with all the screws, bolts, nuts and lock washers for a very low price.

Fix Tire Cement

CEMENTING damaged tires is an important sort of repair work, and a mixture which will contain all the necessary ingredients and after having been applied dries in the minimum of time will be found useful by practically all automobilists. Fix Tire, which comes in paste form and is contained in tins, may be used to repair blow-outs, punctures and cuts of tires and other articles made of rubber, such as hose, blankets, boots, etc. It is made by the Motor Accessories Makers, 80 Jackson Boulevard, Chicago, Ill.

Spring Ball Throttle Connection

THE construction of a free and secure joint of small dimensions will be considered an easy task by many, but undoubtedly it is not the easiest that can be thought of. Such a connection is needed in more than one place on the automobile, for instance, on the spark control and the carbureter adjusting rod, and because of the importance and peculiar character of these parts the ball and socket ought to be strong without lacking in sensitiveness. As may be

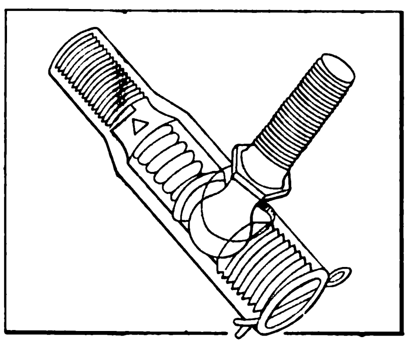

Fig. 2—Free and secure B. & S. spring ball and socket joint

seen in Fig. 2, the connection consists of a cylinder which in its two sections holds the socket. One of the sections contains a spring insuring tension of the socket against the ball, while in the other section is seen a plug, screwed into the cylinder and held in place through the office of a cotter pin. This arrangement insures an efficient connection while the ball end of the joint is allowed a sufficient amount of play. This connection is made by the Billings & Spencer Co., of Hartford, Conn.

Locking Handle for the Tonneau

BURGLARS, however daring, are a comfort-loving lot, and considering a great number of burglary accounts as they appear in the daily papers of this age, it seems that they prefer entering a building, especially a private house, by way of the groundfloor windows rather than through one in the upper stories. Some automobile owners there are who would readily place the joy rider in one class with the real criminals above mentioned, but this is undoubtedly an exaggerated idea. Still, increasing the difficulty for joy riders to enter the tonneau will keep out a good many of them if not all.

The solution of the problem lies in the singular construction of the Security Locking Handle, which is herewith illustrated, showing a Yale lock in the outside end of its spindle which keeps the handle in the "closed" position at all times except when it is turned out of this position by means of the special Yale key. When the key is not in the lock, and the door of the tonneau closed, it is securely locked after a button in the handle collar is pressed in. Afterwards, when the lock has been opened with the key and the passenger entered the car, he locks the door by pressing a button in the inside end of the shank.

The Security handle is made in several types and easily installed on a car, fitting all locks used in closed work. It is not necessary to cut away of the wood pillar in installing the handle, nor is its installation an expensive matter to undertake. It is made by C. Cowles & Co., New Haven, Conn.

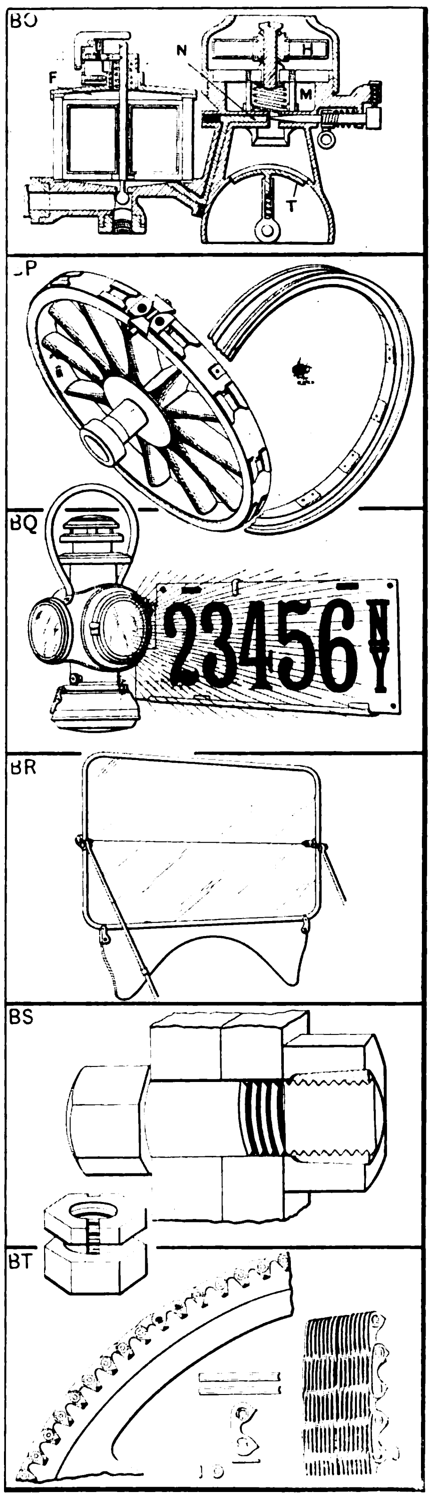
Seen in the Show Window

HIGH engine efficiency is due, to a great extent, to thorough carburetion of the incoming air, and the flexibility of the motor also largely depends on this condition. According to the makers of the Homo carbureter (BO) a very desirable state of homogeneousness of mixture is obtained through the use of the Homo, a small wheel having propeller blades and being placed in the way of the mixture flowing to the engine. As the illustration indicates, the motor suction lifts the throttle T to the necessary and correct degree, while the gasoline coming from the float chamber F is atomized by passing through nozzle N into the mixing chamber M. Thence the charge is drawn through the Homo wheel, where it is completely diffused, to the engine cylinders. The Gasoline Motor Efficiency Company, of Jersey City, N. J., is the maker of this carbureter.

WHEELS, for some forty centuries or so, have been made with the rims rigidly fastened to them, and it remained for the automobile era to develop the demountable rim and demonstrate its advantages. As one type of demountables the Denegre rim is here shown (BP). On its inside this rim has thirteen fasteners having tongues. The wheel rim, too, has thirteen fasteners on its outer surface, and the fasteners are grooved to engage with the tongues of the tire r'm fasteners. A key fits in the opening of the wheel rim, and after the tire rim with the inflated pneumatic has been put in place the key is secured in the opening and tightened by the only bolt which is used on this rim. It is the product of the Denegre Demountable Rim Company, of 1922 Avenue F, Birmingham, Ala.

EVERY automobilist may not be in favor of stringent legislation, but laws must be obeyed as long as they are in force, and to conform with the law the autoist who wishes to keep out of trouble will keep the tail lamp of his car illuminated after the sun has vanished beyond the horizon. Of course, the tail light, which is not intended to compete with the searchlight on the front of the car, but, rather, with the fireflies of the open country, need not be an acetylene light, but a modest oil flame will in most cases suffice to make the number of the rear plate legible. The tail lamp shown at BQ is handled by the Gus Balzer Company, whose office is at 1777 Broadway, New York City.



BO—Section through the Homo type of carbureter
BP—Denegre demountable rim and wheel felloe rim
BQ—Gus Balzer tail lamp for license number plates
BR—Vision automatic windshield without metal division
BS—Columbia nut on bolt and improved form of nut
BT—Link-Belt silent chain and details of construction

YEAR by year automobile builders find ways and means of increasing the comfort of the people who are to ride in the cars made at their factories. Considering only one small portion of this field, it will be remembered that windshields protecting the passengers from the strong air currents, and moreover, inclement weather in certain seasons, are a comparatively novel part of the motor car but one which makes for much comfort. The Clear Vision Automatic Windshield (BR), which is made by the Sprague Umbrella Company, Norwalk, Ohio, has no division strip to obstruct the driver's view, but the two glass plates come in direct contact when the windshield is put up in position, in which it is locked automatically. The material is French polished-edge plate glass.

SIMPLICITY, strength, correct size and accessibility are the chief requirements of lock nuts. Material and labor used in their production must be of quality if the properties enumerated above are to be found in the product, and as an example of the results along this line of effort the product of the Columbia Nut & Bolt Company, of Bridgeport, Conn., is illustrated at BS. The small nut shown in the cut is of the "Improved" type, which has a double castellation, thus permitting of a stronger hold of the wrench upon the nut.

ZEAL of the kind that never tires has made considerable progress in rendering the automobile of to-day a silent performer, and while one army of engineers is occupied with the work of devising silent-moving parts for the power plant, the silent transmission of the motive power to the rear wheels is being developed by another set of workers in the field. In the transmission of the power from the jackshafts to the rear axle considerable measure of silence may be obtained by the use of the "Maximum" Silent Chain, which is shown at BT, where the manner of driving the chain from a sprocket is illustrated. The same illustration shows a side view of some of the chain links, each link consisting of more than a dozen steel plates connected up in parallel and held together through the office of a set of strong bolts and nuts. Returning to the sprockets which the chain connects, they are so constructed as to take up the links during the drive with practically no lost motion, the chief reason of noise in power transmission. The Link Belt Company, of Philadelphia, Pa., manufactures this drive chain.

Vol. XXV. New York—Thursday, August 17, 1911—Chicago No. 7

The Automobile

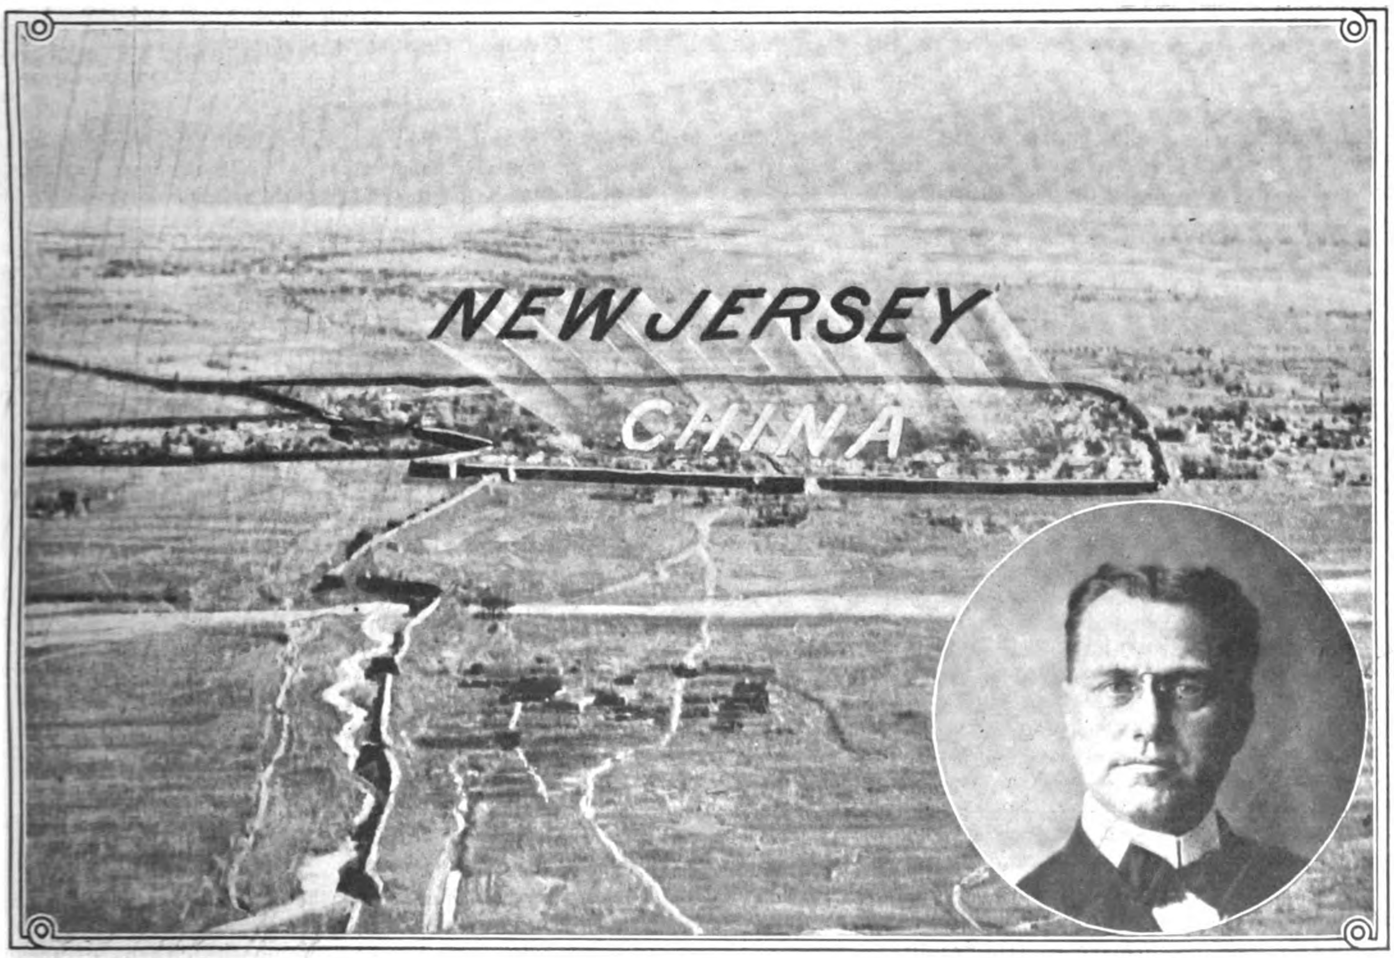
Jersey's Chinese Wall Finished

From Heap-Bunk to Top-Sleep It Is Complete

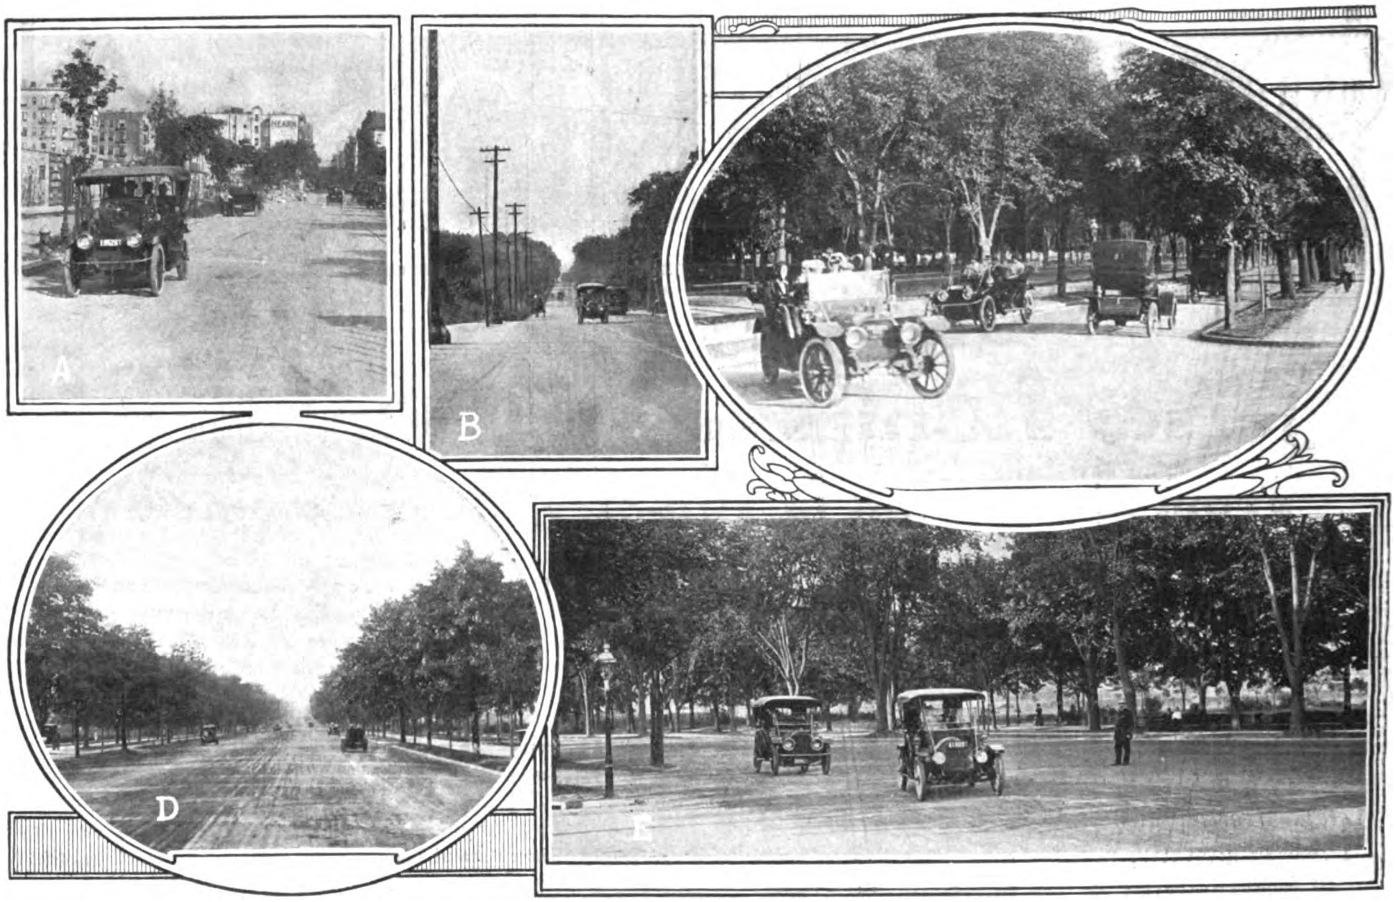
Counterpart of the Great Wall of China, erected by the State of New Jersey to prevent an invasion of American foreigners in automobiles, is finally finished and the last loop-hole, the eight-day touring license, has been abolished. From now on the good roads of Jersey will be almost wholly used by residents, and civilization, as expressed in the development of transportation, will take a backward step. Horse-drawn traffic seems to be unduly emphasized in comparison with its importance and automobiling within the State has received a set-back.

AFTER Quing Wong Duck (or whatever the name of the last Chinese Emperor of the Ming dynasty may have been) completed the Chinese Wall and had it inspected he stood back and said that his work was one of the wonders of the world. Since then succeeding generations have pronounced King Duck's judgment excellent.

After the Jersey Legislature had enacted the Frelinghuysen bill into law, and later modified the law so that Motor Vehicle Commissioner J. B. R. Smith had it in his power to wipe out the eight-day touring privileges, all those interested are given the opportunity now to stand back and pronounce the work another wonder of the world.



JERSEY'S AUTOMOBILE LAWS HAVE ERECTED A VERITABLE CHINESE WALL ABOUT THAT STATE—THE MAN WHO IS ADMINISTERING THEM



A—Between 5th and 6th avenues, New York, looking along 110th street, showing automobile activity

B—A steady stream of cars pass out of New York in the direction of Yonkers

C—Some of the cars that form a constant flow from New York to the Long Island beaches

D—The boulevard as can be seen in this picture is bristling with automobiles

E—The speedway being interdicted to automobile traffic. Automobiles are compelled to make a detour

Both walls were built with the same object in view—namely to foil invaders. The Chinese wall was constructed westward from the Gulf of Pe-Chi-Li along the northern boundary of the empire and when it was finished it measured 1,250 miles in length. It is still 35 feet high and 21 feet wide in long stretches and has watch towers scattered along its whole extent at varying intervals.

The New Jersey Chinese wall extends from Jersey City-Foo Chow, northward nearly to Tappan-Chung and then westward to Port Jervis-Quong Ding and then south through Delaware Water Gap-Ping Bung and east of Philadelphia-Top Sleep to the southwestern corner of New Jersey-Shan Tung to Cape May and north along the Atlantic Ocean through Atlantic City-Heap-Bunk, to Jersey City-Foo Chow again. The wall is a million feet high and half a million feet thick, or at least such an estimate has been placed upon its dimensions by certain New York, Pennsylvania, Delaware and Massachusetts automobilists who have been brought into contact with it.

The Chinese Wall was built because the Chinese believed they had such a fine country that the savage hordes on the north coveted it and sought to plunder it, but the reason for the Jersey wall is two-fold. In the first place Jerseyites have had an extraordinarily good opinion of Jersey roads. They have little else to be proud of in a public-spirited way and consequently they emphasize the beauties of their roads. In fact they think so well of them that they do not want foreigners (*i. e.*, Americans) to enjoy them. Secondly, if the aforesaid foreigners insist on enjoying the roads, why not turn an honest penny?

In times past rapacious country constables and venal peace officers made handsome profits from levying fines for alleged violations of the law. Frequently these fines were paid on the spot, thus relieving the "offender" of the necessity of attending court, and possessing numerous advantages, financial and otherwise, for the constables and others. This became so flagrant after awhile that the State suddenly realized that it was overlooking something good and then the present law was passed.

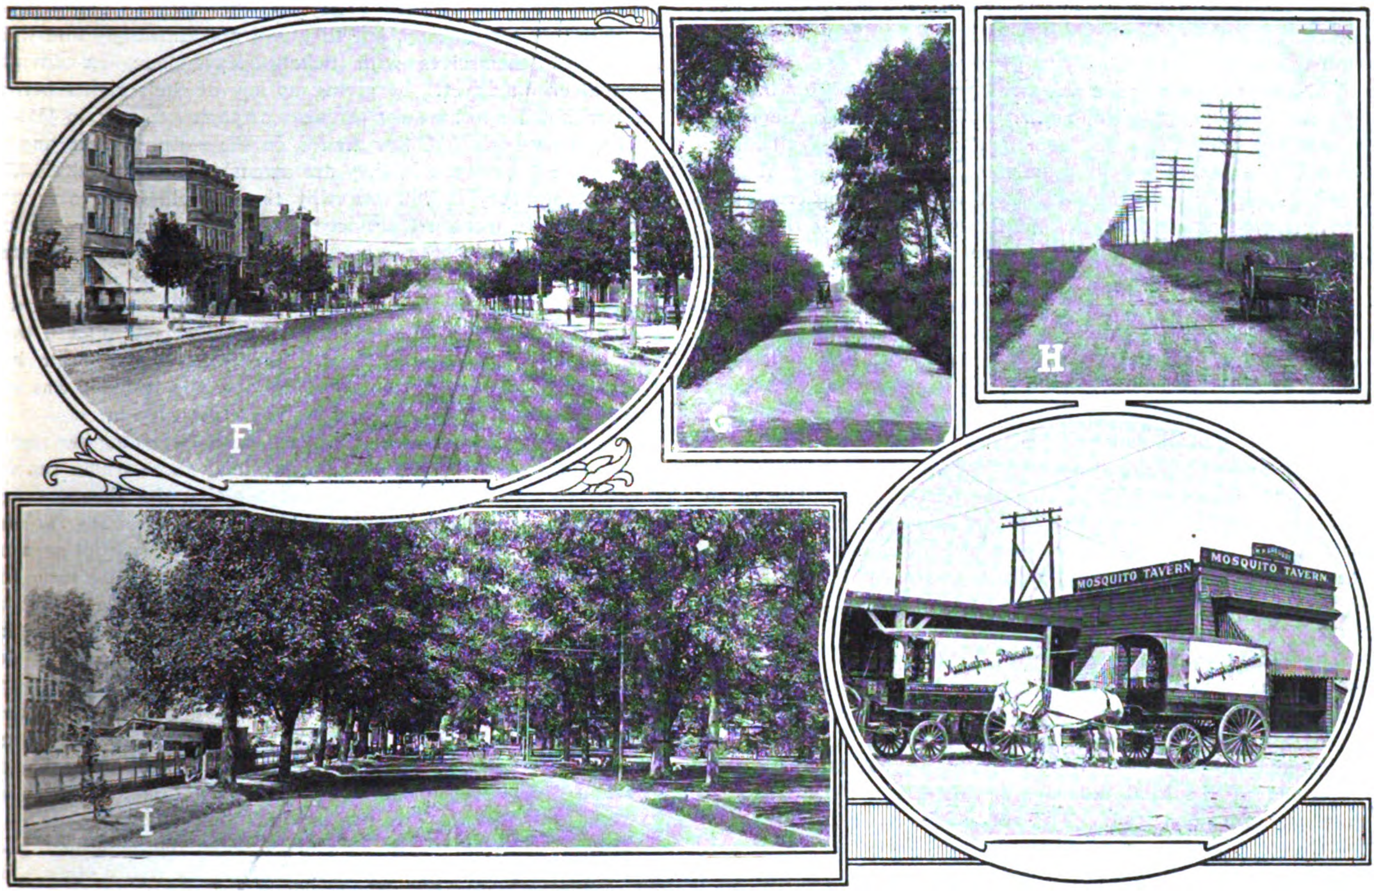
Under this law power was delegated to the Motor Vehicle Commissioner to enforce the law which requires a full season's license from every foreign and native, without benefit of clergy.

One little mitigating circumstance was inserted in the law, which provided for a limited touring license within the sacred precincts, if similar provision had been written into the State law of another State with regard to Jersey citizens. This limited license cost $1 and was good for eight days' riding. Under all the circumstances, eight days in Jersey ought to be enough for any "foreigner" and the arrangement worked fairly well for a while.

Then Commissioner Smith discovered that New York, Massachusetts and Pennsylvania, while opening their magnificent highways to each other, would not have anything to do with Jersey on that basis. The attitude of Jersey in demanding its ounce of flesh from every tourist was called by various unpleasant names, the least offensive of which was "pea-eyed infinitesimal."

New York's grand highway system was open to the Quaker brethren and Massachusetts freely welcomed both families, but as Jersey wanted its dollar a head from every "foreigner" under the most favorable circumstances and a full year's license whenever possible, the doors were slammed against the "thrifty" little commonwealth which lies at the south end of the New York and Philadelphia drainage systems.

Then Commissioner Smith, by virtue of the power which has been construed to reside in him, decided to call in the eight-day licenses or at least to issue no more to the citizens of the "foreign" States and the last loop-hole in the great Jersey



F—This shows the deserted state of the Hudson County Boulevard, a magnificent Jersey highway

G—Jersey possesses some beautiful roads, where the horse can go unmolested

H—The turnpike across the marshes is like the Deserted Village

I—Village streets are covered with leafy bowers, but automobiles are conspicuous by their absence

J—Mosquito Tavern, a pull-up for wagonmen, offers little inducements to automobiles

Chinese Wall was plugged up from the inside and clinched from the outside.

Aside from the fact that all interstate legislation touching automobile traffic is unconstitutional, invalid and void, and will so be pronounced eventually, the situation that has developed is miserable from every point of view.

New Jersey has a large number of automobiles, many of the owners of which have business in New York, Philadelphia and elsewhere. It costs a material sum for the native of New York to gain official sanction from his home State to operate his automobile, and the same may be said for Pennsylvania and residents of other States. But it does not cost the Pennsylvanian a cent to motor in New York if he is in good standing at home, because the Pennsylvania law allows New Yorkers to use the Pennsylvania roads if they have satisfied the legal requirements at home.

Thus, while it only costs the Jerseyman, say, $10 a year for license to operate his car within the State, it costs him dear if he tries to escape. One plunge into New York means a full year's fee; one little slip into Pennsylvania calls for the entire face value of a yearly license and if after making these two excursions the Jerseyman trundles into Massachusetts he is set back for a yearly touring license which will be graciously issued at a price, on behalf of the Old Bay State.

When he gets out of his own bailiwick his Jersey license marks him as fair prey. Everybody knows what happens to one in Jersey under the same circumstances and as a means of reprisal, knowing that the Jerseyman would reverse the positions if he had the power, the "foreigner" plucks him to the bone, without a pang of conscience.

It costs the citizen of Jersey every time he ventures into untried territory and it costs the "foreigner" who invades Jersey. But that is all as far as the "foreigner" is concerned. No other State demands its pound of flesh and gets its ounce except Jersey.

The result is now becoming painfully apparent. Jersey is declining as a touring ground for "foreigners." The magnificent roads are slowly being pecked to pieces by horse traffic and automobiles from outside are growing less and less in value. Automobilists call emphatically to the Touring Club of America and the *Blue Book* for routing directions that will bring them to certain objective points in the South and West without touching Jersey and such information is cheerfully furnished.

In order to show that the attitude of Jersey is deliberate about this matter it may be cited that at the last session of the Legislature one of the solons in contesting the reasonable measure that was being considered said: "This bill must not become a law, because if it is enacted, throwing the State open to automobile touring, our roads will be lined with cars and cannot be used with comfort by our own people."

If such a result could be accomplished by the passage of a law opening the State, it would not hurt the feelings of hotel proprietors, restaurant keepers, garage men, real estate owners who appreciate an advancing market or business men in general who like the idea of plenty of outside money as a motive force for inside business. But far and away the most pleased section of Jersey citizenship would be the dealers in automobiles.

Every little obstacle in the way of pleasurable use of the car limits the market for more cars and when such an obstacle as the Jersey Chinese wall is interposed, the deleterious effect must be felt widely in the course of time. The accompanying pictures illustrate a few of Jersey's fine roads and as they were taken at a time of day when the roads might well be covered with traffic, the absence of automobiles indicates that the wheels of progress have been checked. On the other hand, in the illustrations pictured on Long Island and in other spots outside of the "Wall" the presence of traffic shows that something must be the matter with the Jersey territory.

The law hampers traffic and consequently is bad for business as well as being oppressive to citizens of Jersey and to Americans.

Now the real reason for complaint against the "Wall" is, of course, to a certain extent founded upon the mulcting of automobilists for a money fine, as if there was something criminal in the operation of a car *per se*, but the greater portion of the objections raised do not take the mere money into consideration at all. The chief "beauty" about the Frelinghuysen law is the fact that after the American "foreigner" has paid his yearly license to tour one day in Jersey he must acknowledge that he is incompetent before the law if not actually criminal by signing a power of attorney empowering the Secretary of State to accept legal service in his behalf in case the peace officers or others shall suspect him of violating the law.

If the solons had gone one step further and made the power of attorney broad enough so that the Secretary of State or the Commissioner of Motor Vehicles or someone else could not only accept service but also enter a plea of guilty on behalf of the American in a criminal action or to confess judgment for him in the civil courts the intent of the solons would have been better served.

The legal attitude of the State of New Jersey is an anachronism. It harks back to another age—an age when savage tribes held mountain passes between populous centers and exacted toll from every passer on the highway. There is a disregard of ethics, gentility and fairness in the attitude, but as in all other situations of the kind recorded in history, it must work its greatest harm upon itself. The advantages of quick transit are too thoroughly understood to require argument. The history of transportation is the history of civilization and the automobile is the highest light in the bright pages.

Whatever is done to check transportation and easy communication tends to destroy civilization and points toward chaos.

Jersey has taken a step in that direction in attempting by law to make the use of the automobile unsatisfactory.

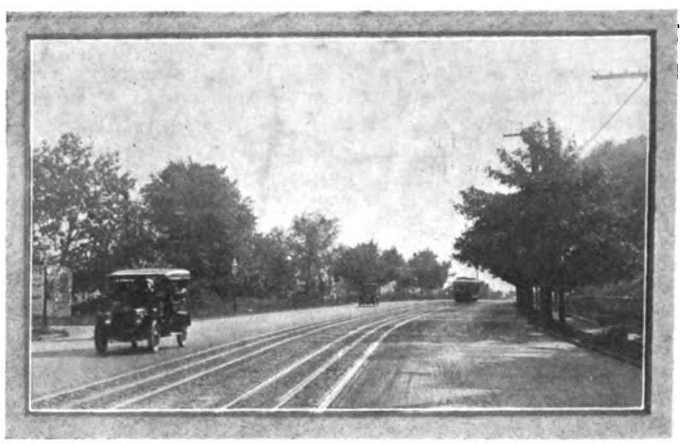
Ordinarily the pleasure automobile is used for its owner's enjoyment. Too frequently he cares nothing what its operation costs and is careless about all the various items of expense that go to make up the grand total. There are hundreds of automobile owners in New York who pay all their automobile bills without giving them the critical analysis that they would if the bills represented some element of a business transaction. The $10, or whatever it is, that it costs for a Jersey license would not be considered for a second as an obstacle to the enjoyment of the automobile owner and yet this autumn will see fewer New York, Pennsylvania and Massachusetts automobiles in Jersey than any year since 1907.

Surely this is not because the owners of the cars balk at the idea of spending $10 more. The fact of the matter is that they will not take out Jersey licenses because they cannot do so and maintain their self-respect. They feel that they do not wish to be hampered territorially, but they will not knowingly and willingly class themselves with ticket-of-leave men, ex-convicts, habitual criminals, etc., by giving up any of their rights before the law in order to have the privilege of paying to tour in Jersey.

They figure that the law stands on the statute books and if they evade it or break it, they are amenable to its penalties and consequently they cannot see why they should hand over the legal right of personal service to an officer of New Jersey, while at the same time the resident of the State is only deemed to be guilty of any crime after due service and conviction in a competent court. Under the nauseous and un-American "Power of Attorney" clause, judgment by default could be entered by a court against a non-resident after the Secretary of State had accepted service in the case, providing the non-resident was not represented in court.

Suppose that a tourist was charged with exceeding the speed laws, or carrying two licenses, or breaking some traffic regulation by some officer in Jersey. Suppose that the alleged crime or misdeamenor was not noticed by the occupants of the car and the officer complaining of the breach of the law was not seen by any member of the party. It is perfectly possible that after the constable has made his complaint and legal service accepted by the Secretary of State that the case should come on for trial without the slightest knowledge of it having reached the defendant. Suppose that the party continues its way out of the State and tours indefinitely through the South, for instance. Upon his return to New York it is conceivable that the owner might discover that during his absence the limit penalty of the law had been imposed upon him. Of course, that would be an extreme case, but there is nothing impossible about it.

A staff representative of The Automobile and a photographer made a tour over a number of typical Jersey roads recently in quest of illustrations for this article and considerable care was exercised in getting accurate pictures showing actual conditions.

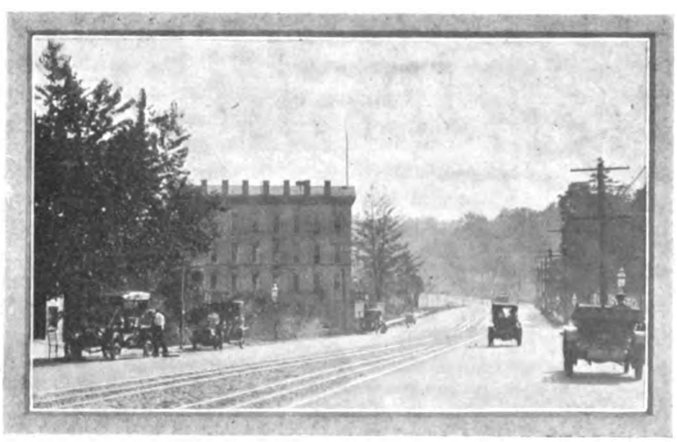


I.—The surface of the Yonkers road has been worn smooth by automobile tires

The trip was made on a week-day between the hours of 2 and 6 o'clock on a pleasant afternoon. The paucity of automobiles was painfully noticeable throughout the trip, as will be noted from an examination of the pictures.

The direct opposite is shown in the pictures taken in and around New York, where every street has cars upon it almost every hour in the day. It costs Americans considerable money to avoid New Jersey and considerable chagrin to think that they are barred from the "sacred precincts," but it costs the Jerseyites much more in money and loss of trade and conditions are gradually developing that will bring these facts keenly to the notice of the Jersey citizen who does not want foreign automobiles to use his roads.

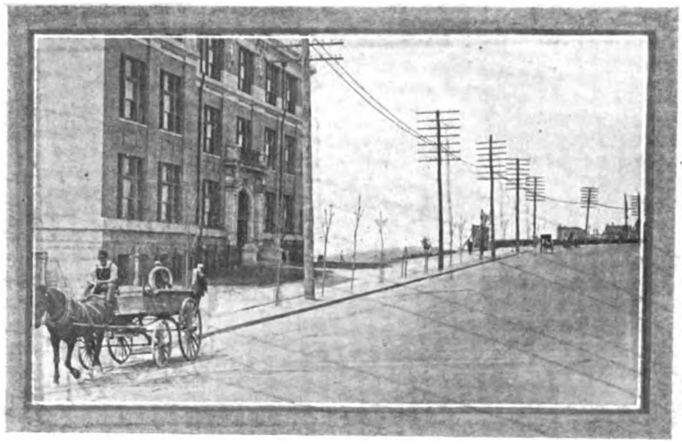
The automobile manufacturing business with its accessory branches and allied interests ranks third in the United States in value. It is growing each season and will continue to grow, according to all indications. This industry was not raised upon



K—Automobile activity along one of the roads leading out of New York such laws as that which disgraces the statute books of the Jersey commonwealth. Such laws are a detriment to the automobile business and consequently to transportation, which means civilization.

There is little comfort to be derived from contemplating the immediate legal future in Jersey, but the life of the present situation must prove short. There are a lot of excellent Americans living in the State. They are not fond of the status of affairs and in the end they will win and the great "Wall" will be shot as full of holes as is its counterpart on the north line of the Flowery Kingdom.

They really represent the American spirit of Jersey and despite the fact that they have not succeeded in abolishing the Frelinghuysen law to date, they earnestly oppose it and if intentions ever forecast action the law will be torn from the books the next time the people of the State have an opportunity to voice their wishes.



N—This fine stretch leading from New York into Jersey is given over almost entirely to horse-drawn vehicles

Mud-Splashing Omnibuses

The nuisance has become so aggravating on the streets of London that the matter has come up in Parliament. It is proposed to scotch the evil by compelling the 'bus companies to equip their vehicles with mud-guards.

THE question of mud-splashing by motor buses in London has become so pertinent that it has got into Parliament, where no less a personage than the Home Secretary, Mr. Churchill, has taken a hand in the matter. So aggravating had the nuisance become, that a meeting of London representative bodies was held at Stratford, as a protest. This conference, "representing twenty-one local authorities in Greater London," having become cognizant of the serious damage and annoyance to persons and property caused by the mud splashed from the wheels of motor omnibuses, "and having regard to the refusal of the Commissioner of Police to take reasonable steps to obtain an abatement of the nuisance," called upon the Home Secretary to intervene and to require the Commissioner of Police to make it a condition of his license that all motor omnibuses plying within the limits of his jurisdiction should be fitted with mud guards.

To all of this, the Home Secretary replied that the reason the Commissioner had not not made the regulation insisting on the use of some form of mudguard which would prevent the nuisance was that, in spite of inquiry, inspection and actual trials, no mudguard had been found which did not entail serious disadvantages and danger. Therefore, he said, "I could not ask the Commissioner to enforce the use of special mudguards till a suitable type is invented." Meanwhile, the motor omnibuses go on splashing mud and the representatives of the twenty-one local authorities in Greater London continue to fume and protest.

Careless Use of Cotton Waste—The interior of enclosed bearings should never be cleaned with cotton waste just before they are finally assembled. Small particles of the waste are apt to be picked up by the oil and carried to a spot where they will effectually clog the oiling system.

New England Hills Free from Heat

Tour of the White Mountains Attractive

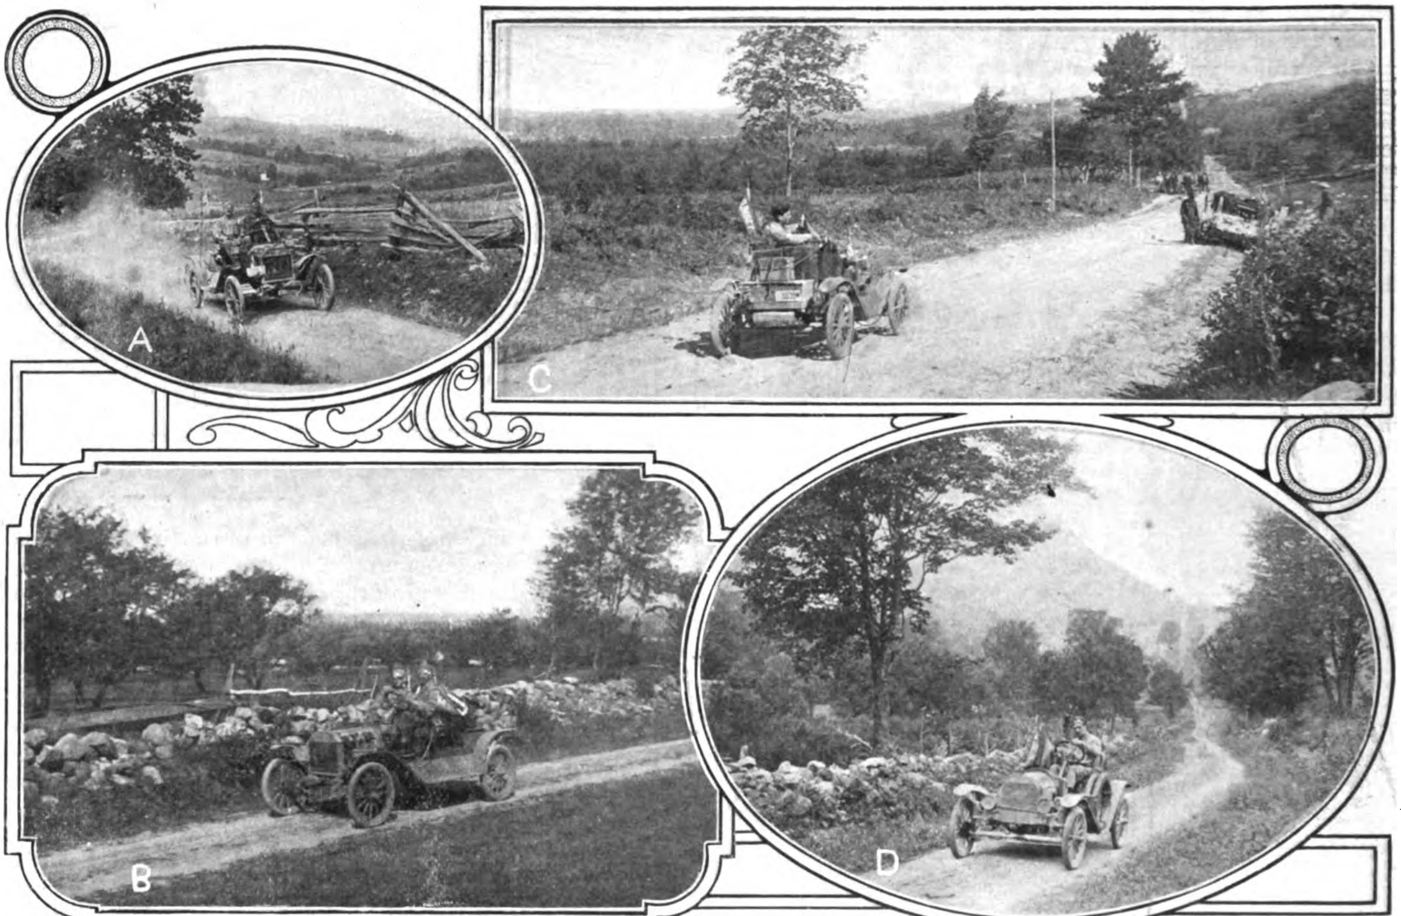
When a change from city or seashore is desired, the automobilist can enjoy the lake country, forest and mountains with a minimum of bother and preparation. One of the most delightful tours possible to take in this section of the country is the two-day run across the White and Green Mountains, passing the celebrated Bretton Woods high in the hills. The scenery is far and away the finest in New England, and many consider it a rival of the Alps.

MAINE, New Hampshire, Vermont and Northern New York are particularly attractive at this time of the year to automobilists, and a trip through the White, Green and Adirondack Mountains holds out compelling charms during the vacation season. When those who may be summering on the Maine coast feel the slackening of interest in the sea and the rocky headlands and the desire to move and see something else becomes a conscious thought, the following suggestion for an automobile tour may strike a responsive chord.

A leisurely run of two days, which may be extended into three or four as fancy dictates, through the Maine forests, across New Hampshire and Vermont to Lake Champlain and as much further as the party wishes affords an opportunity to enjoy the scenery in New England in perfect comfort as regards excessive heat.

Even an ordinary car can negotiate the grades with ease and maintain a running schedule that will be satisfactory. Aside from comfortable underclothing and waterproofs, no special equipment is required for the trip through the mountains.

Starting from Portland via the direct route, which is Route



A—Leaving Montpelier on the last climb of the second day
B—Striking north from the city of Portland, Me.
C—Bethlehem in the highlands of the White Mountains
D—Between the White and Green Mountain ranges

611 of Volume 2 of the *Blue Book,* the road trends northwest, crossing the Presumscot River at Riverton and then skirting Duck Pond on the right, getting a glimpse of Sebago Lake after passing North Windham. Running along the shore of this wonderfully beautiful lake the course passes Naples and then follows the shore of Long Lake to Bridgeton. The main villages and towns passed on this route between Portland and Bridgeton are Morrills Corners, North Windham, Raymond, South Casco, Naples and Bridgeton. The mileage is 39.2 through typical Maine surroundings.

Every few miles a wonderful lake scene is spread before the eyes with its setting of rugged hills and every gradation of green that the forest is capable of producing. From Bridgeton the way leads to East Fryeburg and then Fryeburg, where the foothills of the White Mountains begin to loom up like an impassable barrier to the progress of the car. Just beyond is the State line of New Hampshire at East Conway and at North Conway the route joins Route 403. The mileage thus far is 64.8 and makes just a nice, comfortable all-the-morning run.

Luncheon may be taken at Intervale, a couple of miles further along the way, and after a mid-day rest the remainder of the day's run may be made with ease to Bretton Woods. The road follows a northerly course and swings westward after passing Lower Bartlett.

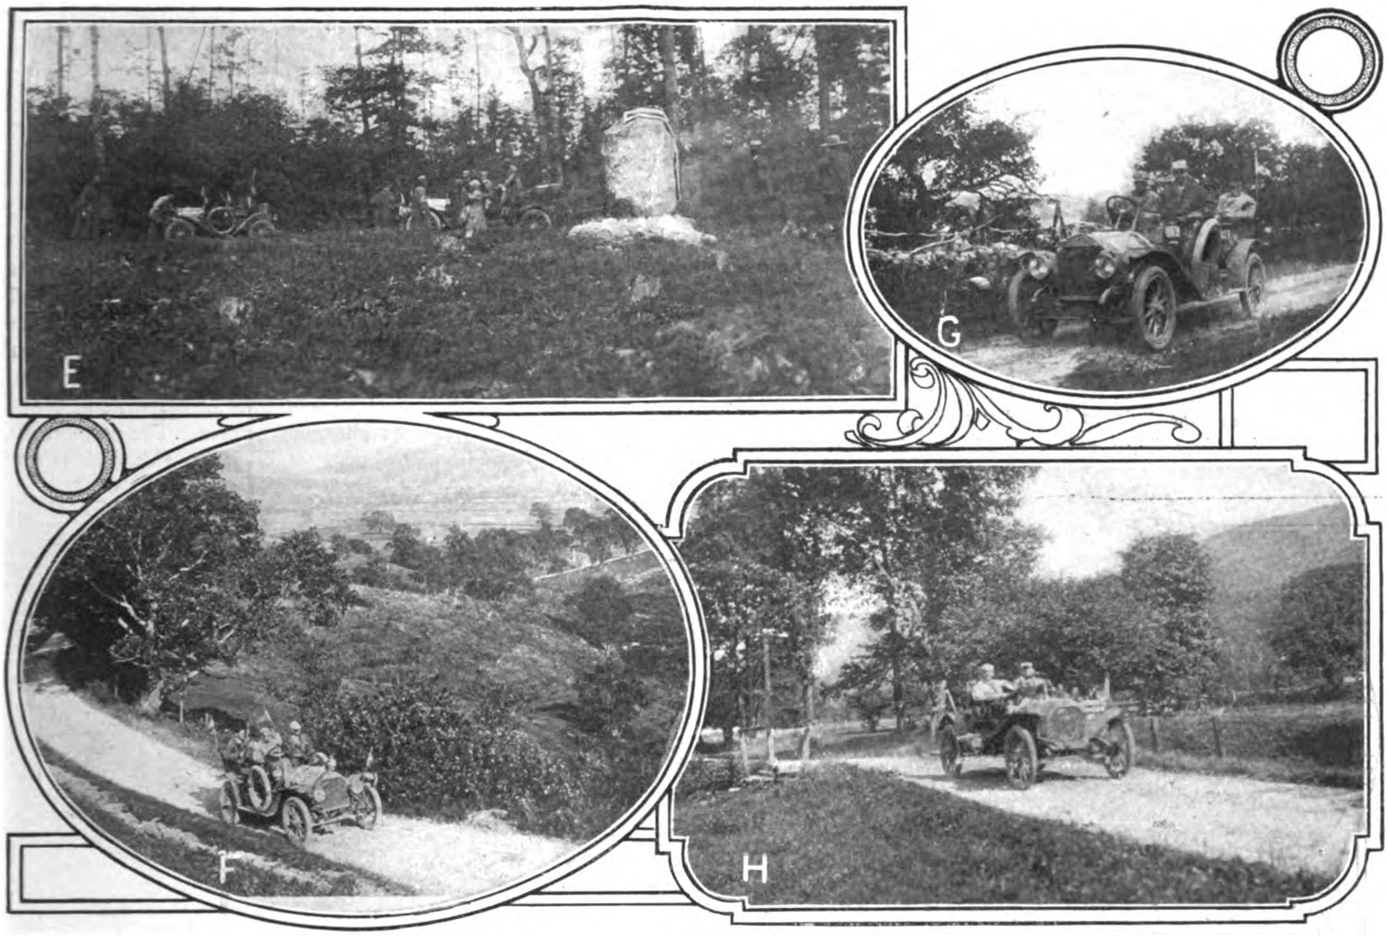
Winding south and then west the road passes Bartlett and continuing west enters the rugged hills. At Sawyer's River the road turns north and climbs past Bemis, Carrigan and Wiley's to the Crawford House. The feature of the day is the passage of Crawford's Notch, a natural gorge through the mountains, that has an interesting legendary history.

It is recorded locally that prior to the Revolutionary War a pioneer named Crawford carried the mails into the little-known Northwest and that he was offered a big land grant if he could lay out a mail route that would shorten the distance between the seaboard and Quebec. Crawford while hunting in the highlands happened to lose his horse and in climbing a tree to get his bearing saw the notch-like groove in the crest of the mountains that seemed to afford the possibility he sought. He did not pass over the notch at that time and the war coming on prevented him from pursuing his explorations until after peace had been secured. Then he received a renewal of the offer by the Government and the test was to be his ability to lead a horse across the mountains. Crawford did this, according to the historians, and won the land grant.

To-day the rigors of the notch have been much ameliorated by road improvements and the cutting down of some of the stiffest grades. From Crawford's the way is through a wild and interesting country to Bretton Woods, where the night stop may be made at either of several creditable hotels. The Mount Washington House, facing toward the giant peak of the range and housing among other conveniences for the automobilists a branch of the Touring Club of America, is a magnificent stopping place, although there are a number of others excellent in every respect.

The day's run by this route is 95.2 miles and is altogether desirable from every point of view. The roads are frequently based upon gravel and well maintained, while in the main they are of dirt, but really rank high in that classification. There are some long steep grades, but they are not excessive and with due care there is no room for fear of mishap.

The second day's trip is via Route 477 to St. Johnsbury, Vt., passing along the Ammonoosuc River and various big resort hotels to Bethlehem and then Littleton. Thence through Waterford, crossing the Connecticut River, the road reaches St. Johnsbury, 37.6 miles across the western foot hills of the White Mountains and entering the ascent of the Green Mountain range. It may be well to take it slowly and enjoy this short run, for there



E—Lowell's Mount, near Fryeburg, Me.
F—Where the Green Mountains smile near Burlington, Vt.
G—Just before the road winds away in Bretton Woods, N. H.
H—Just before crossing the New Hampshire State line

is little in New England that equals this region in scenic beauty.

Route 591 is the accepted way from St. Johnsbury to Burlington and it leads through a country of much charm scenically and much interest historically. The White Mountains have a distinctive, ghostly white aspect viewed at a distance, especially in the twilight, but the hills to the west are as green as verdure even when the searching rays of the sun are glaring upon them. The reason lies in the coloration of the rock in each case. In the White Mountains there is probably an element of limestone that shines white, while the granite of the Green Mountains lends that range its characteristic hue. The tourist will search in vain for a reason for this difference if he confines his investigation to vegetation.

Passing Danville, after steep down and up grades, the road touches West Danville, South Cabot, Marshfield, Plainfield and into Montpelier, the State capital. There is a winding, picturesque road from Montpelier to Waterbury and a few miles further on there is a 15 per cent. hill, which fortunately is short. Reaching Jonesville, the road is up and down to Richmond and after passing that place the way is mostly up until the crest of French's Hill is reached. Looking back over the road and across the valley the view from the hill top is superb. From there to Williston and into Burlington the route is comparatively easy.

The mileage from St. Johnsbury to Burlington is 78.4 and a good five hours will not be wasted in traversing it. If the start from Bretton Woods is made at 9 o'clock in the morning and at least three hours spent in reaching St. Johnsbury, where an hour at most should be spent in refilling with gasoline and oil and getting luncheon, the way to Burlington may be taken up at 1 o'clock and by 6 o'clock the day's journey will be finished.

Such a trip will be memorable. It is like nothing else in this part of the land and for varied beauty and interest rivals anything in the world. The sight of the Vermont valleys from the tops of the mountains is poetically lovely and the roads are not bad, especially in dry weather. There are a few stretches of sand and heavy going, but in the main the going will be found to be fair where it is not better.

All told the day's journey is 116 miles long and at least eight hours of running should be used in making it.

From Burlington there is a choice of numerous interesting routes, particularly the tour to Canada, the one to the north end of Lake Champlain and down the New York side past Plattsburg to Saratoga or to Ticonderoga and thence westward.

Difficulties Attending Exportation

The difficulty of obtaining spare parts without an enormous delay and at great expense proves a great barrier to foreign automobile trade. It would take a number of sales to make it profitable to maintain well-stocked agencies.

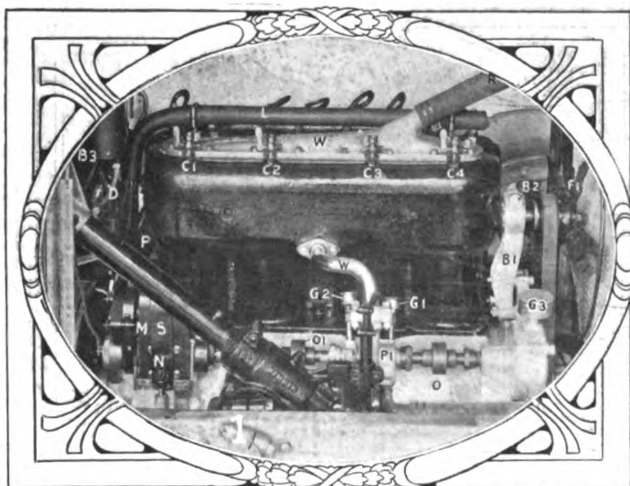
AMERICAN motor cars are not known in Frankfort-on-the-Main, Germany, and dealers do not care to take them up, as they consider it practically impossible, under existing circumstances, to work up a profitable business in handling them. In the first place, the various large German concerns can deliver excellent cars at prices which make foreign competition difficult. German manufacturers have a firm hold on the market and, with the exception of a few French machines, no foreign cars are sold or seen there.

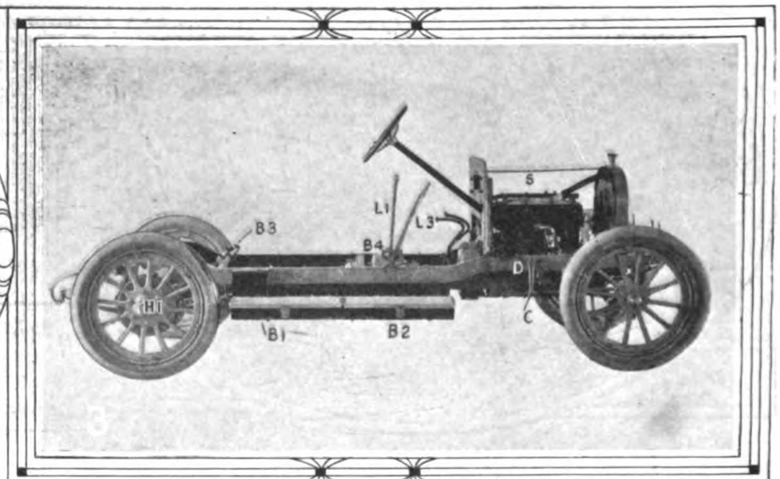
In order to sell American motor cars there it would be necessary to keep up a stock either at Frankfort or some accessible point, where parts could be secured at short notice and where cars could be repaired.

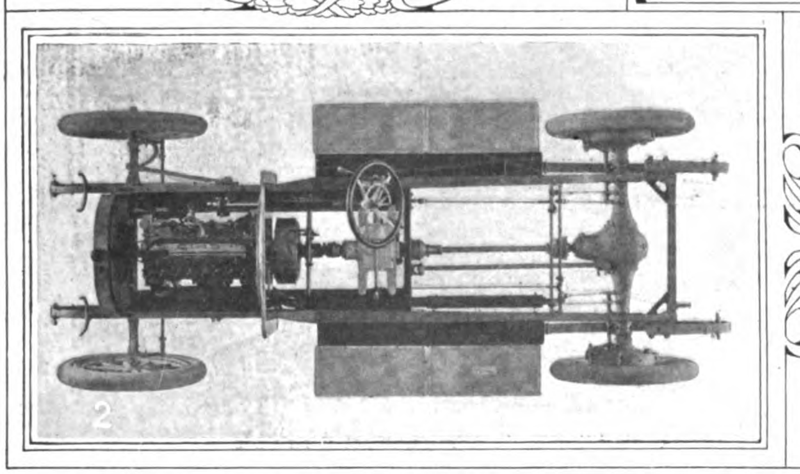
The New Warren-Detroit Models

Describing Their Mechanical Features

In addition to the Warren "30" manufactured by the Warren Motor Co., of Detroit, Mich., two new models have been placed on the market by this concern. The "30" will in future be known as the "12-30," the two new models being respectively designated as "12-35" and "12-40." No material alteration has been made in the design of the "30."







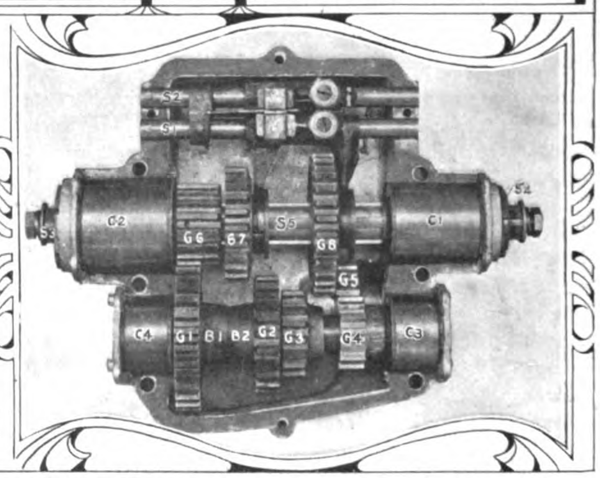


Fig. 1—Right-hand view of the Warren "12-40" motor, showing magneto, waterpump and steering gear

Fig. 2—Plan view of the new Warren "12-40" chassis, showing the general assembly of the units

Fig. 3—Side view of the Warren "12-40" chassis, presenting a clean exterior, showing the neat tool boxes

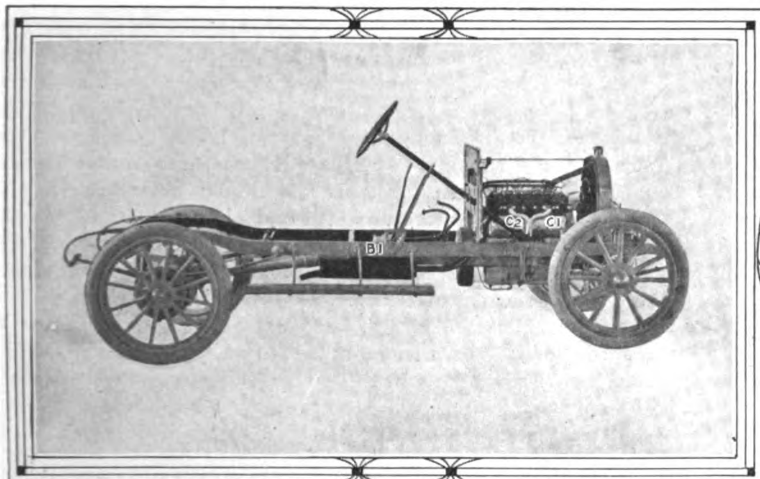
Fig. 4—Transmission of the Warren "35," with the top half removed, showing the relation of the gears

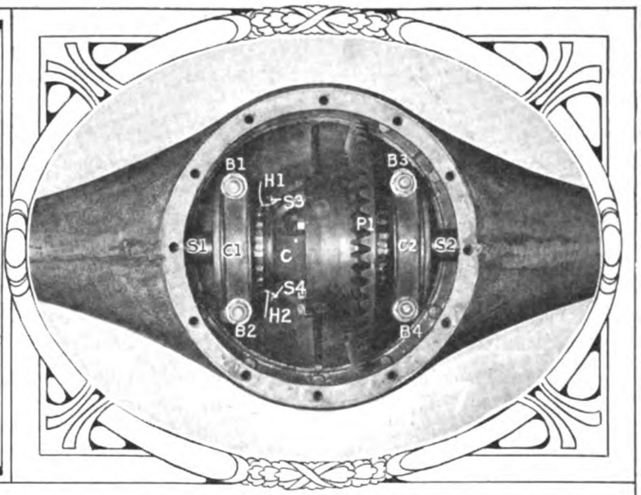
THE motor of the new Warren "40" is shown in Fig. 1, from which it may be seen that the cylinders are cast en bloc with an L-shaped head. It has four cylinders of 4 1-4 inches bore and 4 3-4 inches stroke. The illustration shows the right-hand side of the motor. The water cover W is of cast aluminum and extends the whole length of the cylinders, delivering the water through a rubber connection to the radiator. Compression cocks C1, C2, C3, C4 can be seen and these are fitted with priming cups in the event that it becomes necessary at any time to make an injection into the cylinders, as for instance, when starting in cold weather. The valves are located at the left-hand side of the motor and are 2 1-8 inches in diameter, the push rods, which are adjustable, terminating in revolving mushrooms. The valve springs are entirely enclosed by a neat removable aluminum cover, thus tending to silence the motor. The camshaft is a drop-forging, the cams being cast integral therewith, and runs on three phosphor-bronze bearings. The crankshaft is a drop-forging and runs in three main bearings which are also made of phosphor bronze. The connecting rods are drop-forged and the pistons are fitted with four rings.

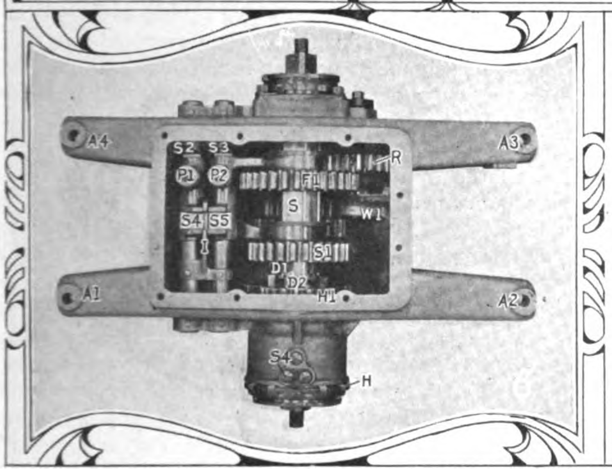
A vertical shaft extending both above and below the motor is driven by suitable gearing from the crankshaft, the upper end operating a timer and the lower end driving the oil pump, which is of the gear type. The oil is taken from the lower half of the base chamber and forced by the pump through a sight feed situated on the dash to the four sumps below the connecting rods, the rotation of which atomizes the oil and forms the splash system. A carbureter of the float-feed type is located on the left-hand side of the motor, being attached to it by means of a bifurcated cast-aluminum intake manifold. The cooling of the motor is effected by means of a cellular-type radiator with 1-4-inch square sections. The water flows from the radiator to the centrifugal pump P1 in Fig. 1, which is driven by the shaft O off the half-time shaft, delivering the water through a single pipe to the center of the cylinder casting. Greasers G1 and G2 are provided on either side of the pump in order to maintain the efficient lubrication and prevent the water leaking through the packing glands, of which there are two. The pumpshaft is extended to the rear and drives the magneto, which is of the Bosch high-tension type. The magneto M rests upon a ledge formed by one of the arms of the motor and is attached thereto by means of a steel band S and the clamp N. In addition to the magneto an independent ignition is provided by means of a high-tension distributor and single-unit coil, which is located on the dash, the distributor being situated on the right-hand side of the motor. Fig. 2 shows the method of suspending the motor upon a sub-frame by means of four arms cast integral with the upper half of the aluminum base chamber. The front end of the crankshaft, which carries the master pinion of the timing gear set, is extended through the front end of the base chamber and a pulley is attached thereto. Fig. 1 shows the bracket B1, carrying at its upper extremity the fan and shaft, and in order to prevent the flat fan belt from slipping an eccentric adjustment is provided. By loosening, the nut B, which holds the clamp bracket tight, and rotating the enclosed boss an eccentric movement is transmitted to the fan shaft, thereby tightening the belt.

The spark plugs, of which there are eight, are located in the valve caps in the cylinder heads, and the wiring is conducted by means of the fiber tube L which is held in position by two clamp brackets fore and aft. Drain and level plugs situated in the lower half of the crankcase afford ready means of ascertaining the correct amount of oil that should be in the motor as well as providing a means of emptying all the oil.

The clutch is of the conventional cone type, the male member being of cast aluminum and faced with leather. The springs that maintain the tension have adjustable slips, and the shifting yoke ring fitted with ball thrust is made so that it can be readily removed. Between the clutch mechanism and the transmission there is a short shaft, each end of which carries universal joints all made of steel forgings. Fig. 6 shows the general assembly of the transmission, which is located amidships and suspended by the arms A1, A2, A3 and A4 upon the continuation of the sub-frame which carries the motor. This frame is attached at the forward end to a cross member of the main chassis and at the rear to the centrally located pressed-steel cross member. This is clearly shown in Fig. 8. The housing of the transmission is a one-piece aluminum casting, the gearshafts being situated vertically one over the other. Referring to Fig. 6, it will be seen that the primary shaft S provided with integral splines carries the sliding pinions. The pinion H is in constant engagement with a secondary shaft and is fitted with dogs D2, and when the dogs D1 are caused to engage with D2 by sliding the rod S2 forward the direct drive is obtained. The pinion S1 when slid rearwards engages with the second speed gear-wheel of the secondary shaft, thus providing the second speed. When the sliding member S3 moves forward the pinion F1 is forced to engage with the secondary shaft gear-wheel by means of the lever arm engaging with the collar. The reverse pinion is shown at R. Slots S4 and S5 accommodate the drop arm, which is in direct communication with the change speed lever, and a slide I is interposed between these







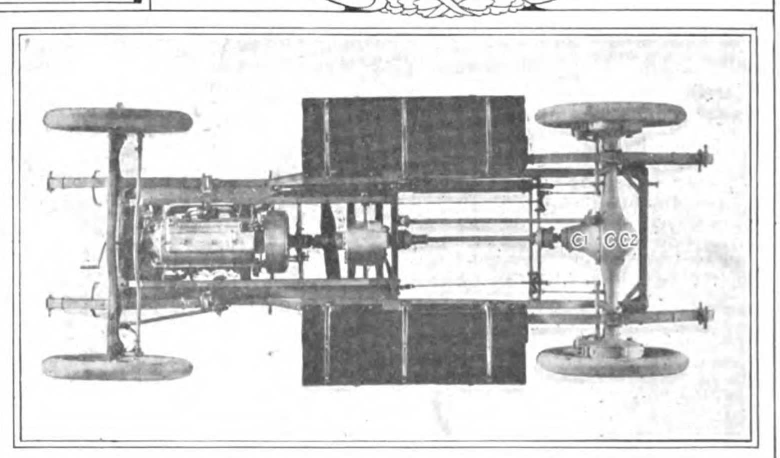


Fig. 5—Side view of the Warren "35" chassis, from which it can be seen that cleanliness has been aimed at

Fig. 6—Plan view of the transmission of the new Warren-Detroit "12-40" chassis, showing the long suspension arms

Fig. 7—Interior view of the rear axle of the 40-horsepower model with the front cover removed

Fig. 8—View of the 40-horsepower chassis from underneath, showing how the running boards are attached to the chassis

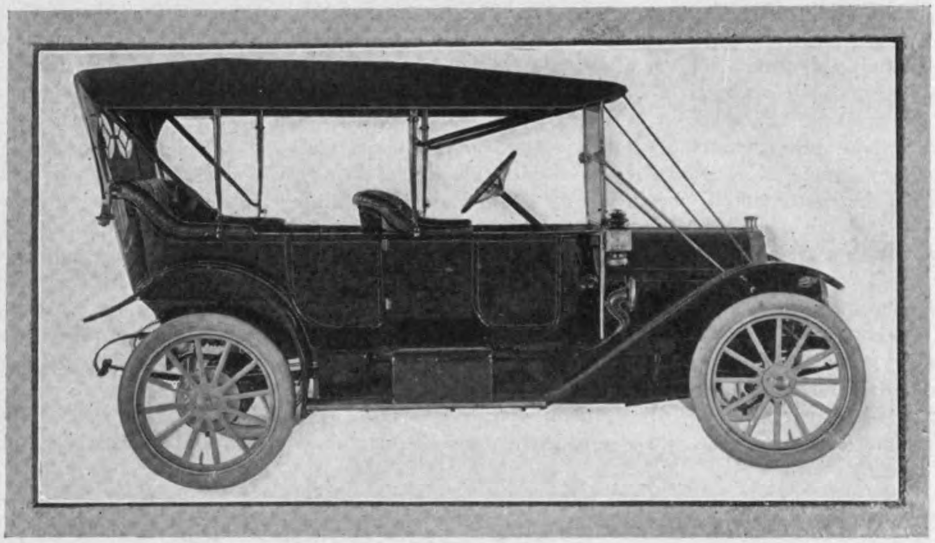

Fig. 9—Warren "12-40" fore-door touring car with flush-sided body

two in order to prevent the engagement of two sets of gears at the same time. To maintain the gears in proper mesh the slides S3 and S2 have V-notches cut in them and corresponding plungers housed in P1 and P2 and spring-urged, engage with the notches and thus hold the gears in position. Ball bearings are used throughout the gearbox for carrying the shafts and are mounted in cages held in position by the retainer S4.

Feature of Rear Axle Is Its Accessibility

A general idea of the rear axle can be obtained from inspecting Figs. 2 and 8. The extension of the gearbox shaft is squared and receives half of the forward universal joint which engages with the propeller shaft, the rear end of the latter terminating in a second universal joint. The housing of the rear axle is a drop-forged steel stamping fitted at the front and rear with removable covers. The forward cover C1 in Fig. 8 carries the driving pinion and shaft as well as the torque tube shown in Fig. 2. The axle proper is of the full-floating type, fitted with ball bearings throughout, and Fig. 7 shows the general arrangement of the interior. The main ball bearings supporting the extensions of the cage C are held in position by the clamps C1 and C2. In order to remove the differential bodily, these clamps may be removed by taking off the nuts B1, B2, B3 and B4 after the jackshafts have been withdrawn. A general view of the chassis is obtained by reference to Fig. 3, from which it will be seen that the forward suspension is taken care of by semi-elliptic springs 2 1-4 inches wide and 38 inches long, while the rear suspension is of the three-quarter elliptic type with the same width of the springs as obtains in front, but 48 inches long. The bolts carrying the springs are hardened and the spring eyes are bushed and fitted with greasers. The frame consists of pressed-steel side members united at three points by cross members, and as before stated a sub-frame is provided for the suspension of the motor and transmission. The front axle is an I-beam drop-forging and the steering knuckles and arms are drop-forged also, the wheels being fitted taper roller bearings. To prevent change-speed and brake levers from interfering with the body construction the bracket carrying these parts is mounted upon, instead of at the side of, the chassis. This eliminates unsightly brake levers outside of the frame and the running boards are formed into compartments 4 inches deep for carrying tools and similar accessories.

Two sets of brakes are provided and operate upon a 14-inch drum attached to the rear wheels, the service brake, operated by a pedal, being of the external contracting type, while the emergency brake expands inside the drums. The wheelbase of the "40" model is 116 inches while the tread is 56 inches as a standard; for Southern trade, however, a choice of 60 inches is given. Artillery wheels with 1 1-2-inch spokes are equipped with demountable rims which carry 34 by 4-inch tires.

Particular attention seems to be paid to the body work fitted to the Warren chassis, eliminating everything that is superfluous, and including in the purchase price, which is $1,700 for the 40-horsepower model, almost everything that is required for comfort. The general equipment includes headlights, side and tail lamps, mohair top and automatic wind shield with other minor refinements.

Passing to the new "35" model, the general details incorporated in the larger model apply to this type. The motor is cast in a similar manner and has a bore of 4 1-8 inches and a stroke of 4 1-2 inches. The valves in this motor are located on the right-hand side as may be seen in Fig. 5, which shows the valve covers C1 and C2. The difference in the price between this model and the 40-horsepower car is in a measure due to the size of the motor. The rear axle of this model is not of the full-floating type and the brakes are 12 inches in diameter. A general view of the transmission is shown in Fig. 4. It will be seen that this type has the housing divided in two halves with the shafts lying parallel to one another, horizontally to the frame, the shafts being carried on roller bearings. G6 is the master pinion with which G1 engages; G7 in mesh with G2 gives second speed, and the first speed is obtained by meshing G8 and G3. The reverse is obtained by engaging G8 with the intermediary pinion G5 which is in constant mesh with G4. The direct or third speed obtains when the gear G7 is slid along the shaft forward so that G6 enters in the interior of G7. The lay shaft is always running as the gears G6 and G1 are constantly in mesh.

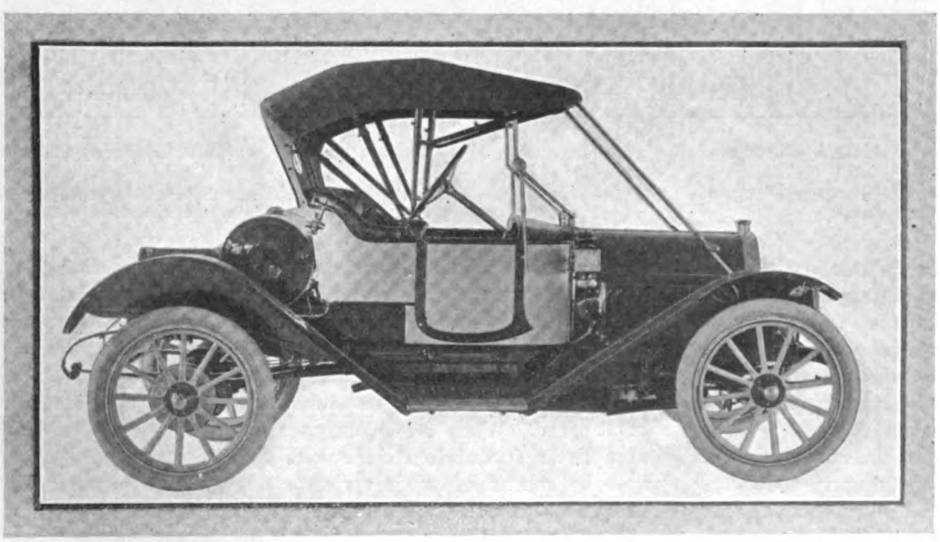

Fig. 10—Fore-door runabout fitted to a "35" Warren chassis, with top, wind shield, gasoline tank and trunk

Previous mention has been made of

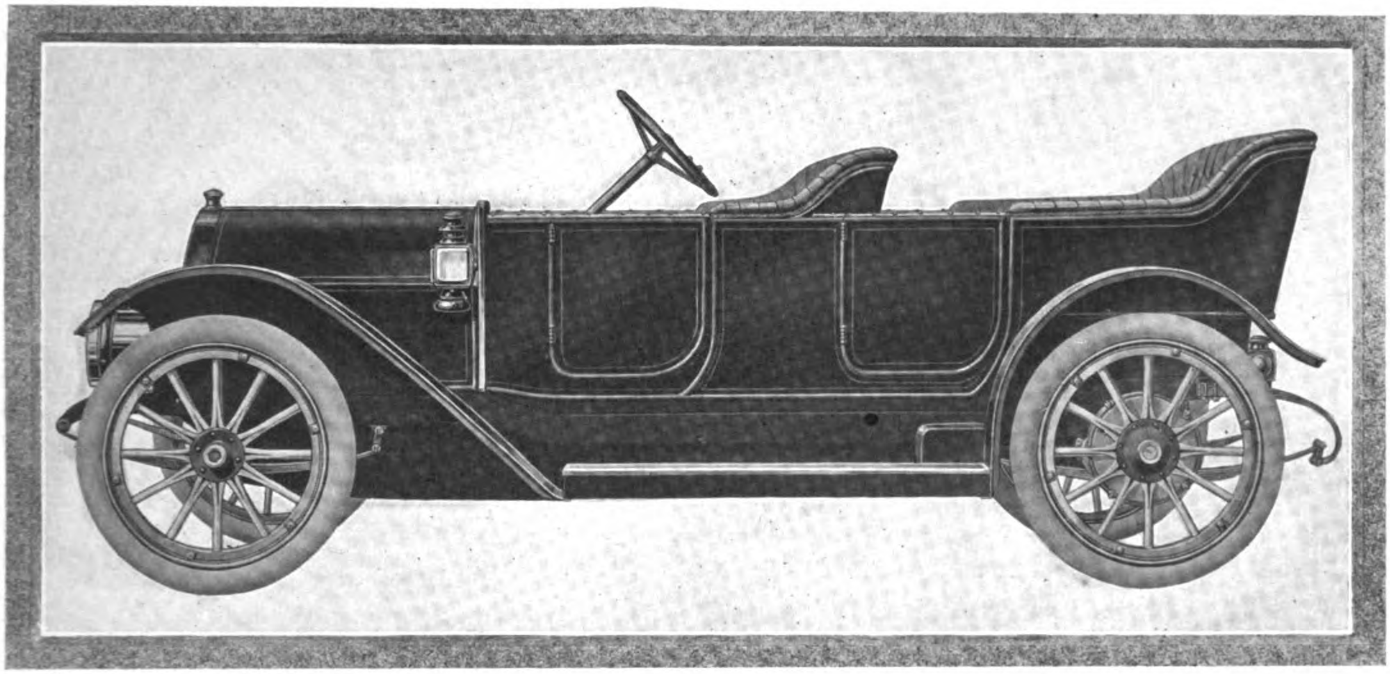

Fig. 11—Standard fore-door touring body fitted to Warren "35" chassis with restrained body line giving a straight-line effect

the Warren "30" in this article, and it only remains to state that the car is in every mechanical essential the same as last year's model. The motor, which has a bore of 4 inches and a stroke of 4 1-2 inches, has remained unchanged and the same applies to the transmission and axles. Additional equipment has been included in the price of this year's car, however.

Useless to Worry Over Valve Stem Lubrication

After the engine has been running for a time a film of oil will be found to have collected on the valve stem which amply lubricates the same, and, if a little pulverized graphite has been placed upon them in assembling, no trouble will be experienced.

IT is quite practicable for valves to work without any attention, so far as their lubrication is concerned, as after the engine has been running for a while a slight film of oil, which has found its way past the cylinder, will have collected upon the stems. If the cylinders are over-lubricated the oil is apt to collect on the stems, gumming them and causing them to stick to their seats.

Where there is any tendency to stick it would be well to allow some kerosene to pass through them. This is a great cure for stickiness on the part of the valves and will be found to relieve them at once. The greatest evil which can occur from an excessive amount of oil reaching the valves is that of carbon deposit. This would, if it held the valve open, cause a loss of compression and hence of power.

Care on Country Roads a Necessity

A lack of foresight is a dangerous thing on a country road where a sudden turn may bring the unwary automobilist face to face with a machine speeding in the opposite direction, with a driver who is also unprepared for the contingency. Ditching a machine is at best a dangerous and unsatisfactory entertainment.

UNDERESTIMATING the other fellow, while as a rule a rather unsafe principle, becomes at times the very essence of safety. In touring about the country there are various contingencies which arise. Whether these contingencies can be classed (after the trip is over) under the heading of incidents or accidents depend upon such a variety of things that it would be impossible to start to analyze them. The largest factor in keeping them under the former head is that of foresight.

There are any number of short "S" turns which are so completely banked off by intervening trees that two cars approaching from opposite directions would hardly have time to veer off to the edge of the very narrow road unless the warning horn was sounded before the turn was negotiated. There are other numerous types of curves and other road conditions which should enforce upon the careful driver's mind the necessity of keeping his attention fixed on the road if he hopes to offset the approaching driver's mistakes.

Buy Suitable Spark Plugs

Spark plugs as well as any other kind of plug are made in different lengths. It is possible to buy them either too long or too short, as it has been found by experience that to have either one of these two conditions represents a fault.

ONE of the great reasons why motorists do not get the best possible results from a very good engine is the fact that the spark plugs may be unsuited for the spark-plug hole by either being too long or too short. If the spark plug is too short the spark is concealed around a bend or behind a wall of metal which interposes itself between the spark aperture and the combustion space. When the plug is too long, the end is apt to glow after a prolonged contact with the hot gases. The spark plug in this case projects so far into the cylinder that it does not get the benefit of the waterjacket space which only can effect the upper part of the plug, leaving the lower extremity subjected to the extreme temperatures of combustion.

The glowing spark-plug points will ignite the gases long before the proper time and will cause them to rapidly burn away or fuse together.

The ideal condition is obtained when the end of the spark plug is just flush with the bottom of the spark-plug aperture in which case the plug is kept cool and the spark occurs in the correct place.

ALTERING VALVE LEAD—The lead of a valve can be altered at any time independently to the cam, by setting the teeth of the timing gears differently.

Improving the Roads of the Dominion

The Automobile Club of Canada is devoting much time and money to the improvement and marking of the roads. Efforts are afoot to improve and properly signboard the international road between Montreal and Rouse's Point, N. Y.

IN considering the subject of roads in Quebec Province, Canada, it may be said that Government intends to expend the sum of $250,000 during the present year for improvements and the making of new highways. One must not lose sight of the fact that the Automobile Club of Canada is eminently visible in every phase of enterprise in connection with the construction of these highways. As a single instance, it is due to the club's persistent work that the authorities of Quebec Province were induced in the year 1910 to increase the State subsidy for the upkeep of roads from the original 50 per cent. basis to 75 per cent.

The revenue derived from all fees collected and penalties imposed within Quebec Province under the section known as "Application of Revenue," is transmitted to the Department of Agriculture, to be applied to the improvement of Provincial highways. Fees and fines have amounted to the sum of $50,000 during the fiscal year just ended.

The members of the Automobile Club of Canada have at their own expense already succeeded in establishing permanent guide signs and caution signs in several sections of the Province, and especially along the international road which extends a distance of 51 miles, covering the course between Montreal, Canada, and Rouse's Point, New York. At the present time they are concentrating their efforts to induce the Quebec Provincial Government to build a State road from Quebec city (the route taking in St. John), to Rouse's Point, a stretch of 230 miles. The line cuts through many localities of signal historic interest. During the year 1910 the club brought about the building of 15 miles of first-class roadway along the South shore of Montreal Island.

Registration figures show that there are 4,000 automobiles in commission within the Province of Quebec. Of this number 1,400, or more than one-third of the total, are maintained in Montreal. Quebec Province has a multitude of drawbacks not found in Ontario; for instance, one of the most serious is the absolute refusal on the part of the Provincial authorities to permit automobilists even to pass through the territory in many sections, while no owner residing within the forbidden lands may own a motor car with the view to driving it there. One of the most hostile sections is Prince Edward Island.

At the same time, it must be admitted that the motorists residing within Quebec Province are doing all in their power to induce the authorities to pursue modern methods of road building and put the Provincial highways in proper shape to accommodate automobile traffic.

Montreal is the center of activity in the matter of automobiles, so far as their propagation as vehicles of travel is concerned. There is no company in Quebec Province which is devoted to the manufacture of motor cars, not even of bodies or parts. The man who sets his mind upon possessing an automobile, buys one that is made either in England, France or the United States—with now and then an exception in the way of an Italian-made machine. But the large majority of the 4,000 motor cars in use in Quebec Province were made in the United States. There is a duty of 35 per cent. on automobiles imported into the Dominion.

If the owner of an American-made motor car were asked why he chose that particular type of machine he would invariably answer: "Because of our closeness to the United States, and the readiness with which we can get parts, in case of an emergency. It means only four-and-twenty hours delay at the utmost; while if we were to order parts by cable from England, France or Italy it would necessitate a delay of at least a fortnight, if not longer."

There is no chauffeurs' club within the Province. The average wage paid to the driver is $15 per week. Every person other than a chauffeur who drives a motor car pays a license of $5 per year to operate his machine. Besides he is required to pay an additional registration fee annually, based on the following graduation: Motor cars up to 25 horsepower are each taxed $5; from 25 to 35 horsepower, $10; from 35 to 50 horsepower, $15, and $20 for every automobile above 50 horsepower.

Quebec Province maintains reciprocal touring relations with such States within the Federal Government as permit Canadians to cross their borders bearing a Dominion license.

The laws governing the operation of motor cars in Quebec Province are quite strict. A fine of $10 is imposed, or sentence to imprisonment for not less than six months is inflicted (within discretion of the magistrate) upon "the person who interferes or tampers" with a vehicle without the permission of the owner thereof.

The law regulates the speed limit to nine miles per hour in towns and cities and to fifteen miles per hour in the open country.

The streets of Montreal, which city is the center of automobile activity in the Province, are so narrow that they constitute a continuous source of annoyance to drivers of every sort of vehicle, motor cars in particular. Fifty per cent. of the paving material used in Montreal is asphalt. The putting down of wooden blocks has been discontinued entirely. The cost of laying asphalt, including a 6-inch concrete base and a "cushion coat" of asphalt, for the fiscal year just ended was $2.11 per square yard. There are two municipal asphalt plants, devoted chiefly to repair work.

France to Change Its Rule of the Road

In July of next year the direction of traffic on the highways of France will undergo a transformation, the present keep-to-the-right rule being superseded by a law similar to that which now obtains in the British Empire, where all traffic keeps to the left side of the road.

FRANCE has flopped over from the right side of the road to the left side, and at the beginning of July, 1912, "the rule of the road" in France will be reversed, and traffic, instead of keeping to the right, as in the past and at present, will be compelled by the law to drive on the left-hand side of the road after the manner of the custom which obtains in Great Britain—even including Ireland. There was a long series of meetings and sittings of the Commission empowered to take the matter under advisement. It is not for the purpose of imitating the British system that this change has been brought about. The movement is due to two causes: First, the enormous increase in the volume of motor car traffic; and, second, the influence which British-made automobiles have had on the designs of machines manufactured in France.

It was sometimes the practice in the early days of the Continental models for designers to have the steering apparatus on the left, thus compelling the driver to sit on the off-side, this having been the best position for managing his machine in the midst of traffic. While this was a point of vantage in Continental Europe, where traffic was directed to the right, the reverse was the fact in Great Britain. And as the English-made cars increased in number, France woke up to the fact that it behooved her to fall into line. Consequently, the French set out to build their automobiles for use in Europe on the British model, so far as the steering wheel is concerned, and having gone in for motor cars after this pattern, they have found it absolutely necessary to alter the rule of the road.

Some Problems of Live Rear Axles

How Selling Points Interfere with Success

It is suggested here that the salesman, who no doubt has his foot upon the cash-box, too often dominates the construction situation, demanding talking points at the expense of quality of the product, and in making his demand the salesman also makes it impossible for the manufacturing department to properly comply with the same because he fixes the price too low to pay for the work that he wants.

MANUFACTURING automobiles, speaking broadly, is attended by many serious difficulties that do not obtain in the other arts from the manufacturing point of view, and in looking into these problems it takes but a little investigation to disclose the inharmonious relations that are at the seat of the most formidable of these troubles. The sales end of the automobile business dominates the situation to a far greater extent than might be generally understood, and the engineers, as well as the constructors in the shops, are too often engaged in the business of giving to salesmen the greatest number of "talking points" that can be brought under one "canvas," not at a price which is made up by determining the cost and adding a profit, but at a price that the salesman fixes at the time he makes his demand.

There is no possible chance of realizing a good automobile out of a salesman's demand, although he, in his diplomatic way, calls his every demand a mere recommendation. A good salesman is rarely ever capable of appreciating the purely mechanical necessities; his scientific training is confined absolutely to the science of wringing money out of the pocket of a "prospective," and his honesty of purpose, however good it may be, is without value from any other angle of view than his own.

Fortunately, the maker of the better type of automobile employs engineers and other "talent," which, under proper direction, produce the type of car that constitutes a selling point in a broad sense, leaving it to the salesman to enlarge upon the details.

Unfortunately, and let it be said, for the maker as well as for the prospective, the car that is composed of a miscellaneous assortment of selling points aggregated at the instance of the sales department is so lacking in harmony of the relations of these selling points that it would be unnecessary to annoy the engineer of the company, which is all that could happen were he to be employed for the purpose of producing this product.

Of course, it is claimed for every plant that it has an engineering department, but too often some high official usurps this function, and it goes without saying that a man who is trying to keep the ends of his investment from getting away is the very type of man who is likely to fall into the trap that the salesman sets and this type of engineer agrees to, he not knowing, of course, that a real engineer would put his taboo upon any such activity, and that the poor devils who are told to make an automobile out of selling points are merely working for so much a week, knowing perfectly well that the automobile so made will be a thorn in the side of the purchaser, and a stumbling block for the company that builds it to stub its company toe upon.

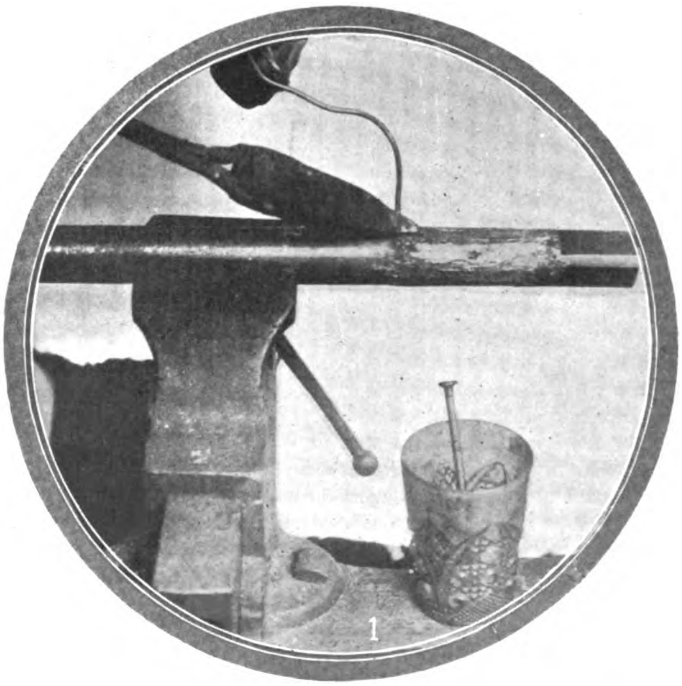

Fig. 1—Showing how the jackshaft may be tinned to increase its diameter so as to prevent leakage of lubricant

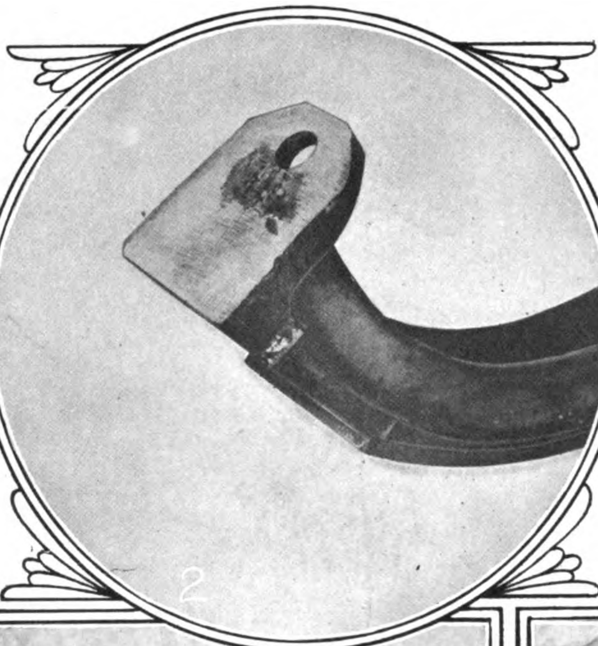
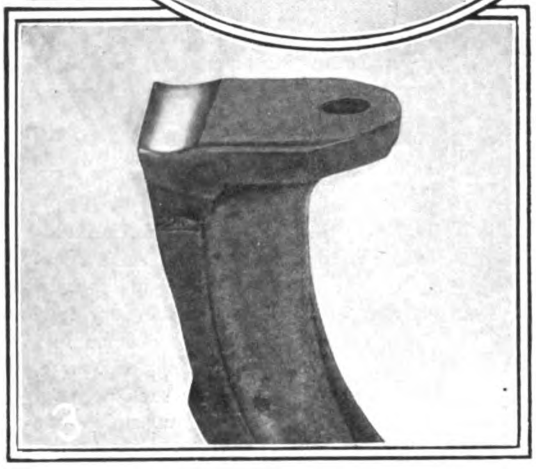
in a position to rectify the mistake in the current series, and it is quite possible that mistakes are perpetuated.

Mention has previously been made of building cars at a price fixed by the selling department, leaving the designer no other choice than to evolve a car that will not cost more than a given amount. This method will eliminate refinements and will cause the purchasing department to be guided more by economy than intrinsic value. Manufacturers who do not manufacture the entire car themselves have a good deal to contend with, as they cannot be personally responsible for the goods that are turned out by parts makers. There is just as much necessity for the maker to have a representative, either traveling or resident, who looks after his interests at the parts factories, to assist in the calibration and see that it is properly carried out, as there is to maintain such a department in the factory proper.

Initial price cutting recoils on the maker's head, as will be conceded by any right-minded person, since it will be necessary for the purchaser to remedy the shortcomings by replacing such new parts as show early wear and resorting to artifices in the endeavor to overcome constructional blunders. Matters being in this state, it is proposed to show by the use of illustrations how some of the inherent defects of live rear axles may be overcome.





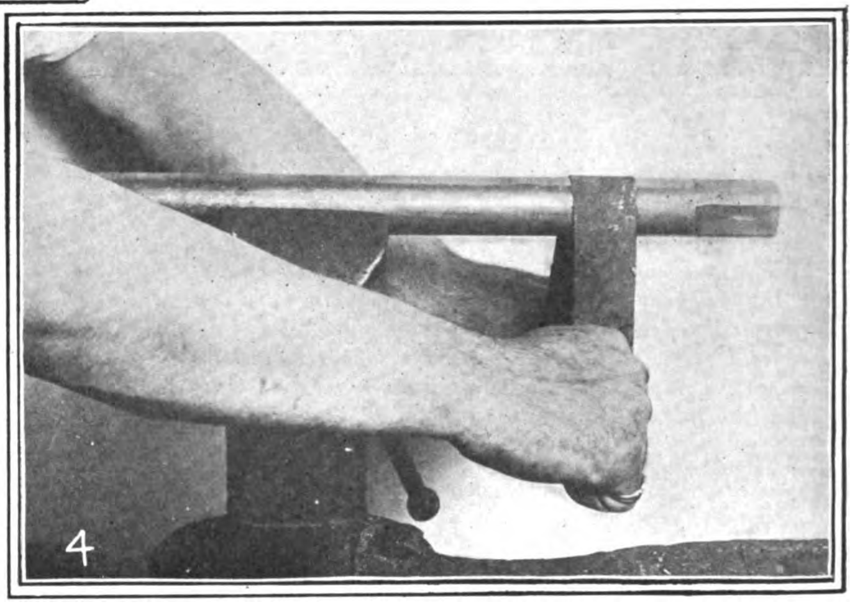


Fig. 2—Showing a worn brakeshoe after having been repaired by the oxy-acetylene process

Fig. 3—Depicting the worn shoe before being fixed up

Fig. 4—Cleaning a shaft with emery cloth preparatory to tinning, also useful for cleaning up a burr

There is no part of the car's mechanism that offers more fruitful thought for the competent designer than the live rear axle and its component parts. The full-floating type of axle with a pressed-steel housing, if properly made, is comparatively light when compared with a webbed casting and the independent assembly of the jackshafts permits of more careful adjustment of the differential proper. The live rear axle is as much in need of lubrication as the motor, yet it is surprising how this one item alone has been neglected or perhaps side-stepped.

A conversation that recently took place in an automobile factory reveals the state of affairs in a nutshell. After a five-hour road test the car was rolled to the running shed and the tester's sheet showed that it was ready for delivery to the customer in perfect working order, and when questioned by the chief engineer the tester stated that it was the best car that had been turned out so far. That may have been the case, but after the test the rear wheels and tires were bespattered with nearly as much oil as it would require to fill the rear axle casing. When the tester was asked if he thought that it was proper to pass a car in that condition his reply was: "Why, they're all like that, and you can't stop it."

It is true that the tester could not be blamed for the construction of the axle, but, nevertheless, it was his duty to report that each and every car that he tested had this defect. Unless the engineering force is apprised of such shortcomings, they are not in a position to rectify the mistake in the current series, and it is quite possible that mistakes are perpetuated.

The oil-leaking propensities of some rear axles may be remedied by tinning or brazing the shaft, thereby reducing the aperture through which the oil finds its way. This may be seen by reference to Fig. 1, in which a jackshaft is shown in a vise, and the operator in the action of tinning the shaft. It is preferable to put the shaft in a lathe after the tinning operation has been completed, but in cases where it is unhandy emery cloth in the manner shown in Fig. 4 will answer nearly as well. The operation shows the shaft being cleaned up prior to the tinning.

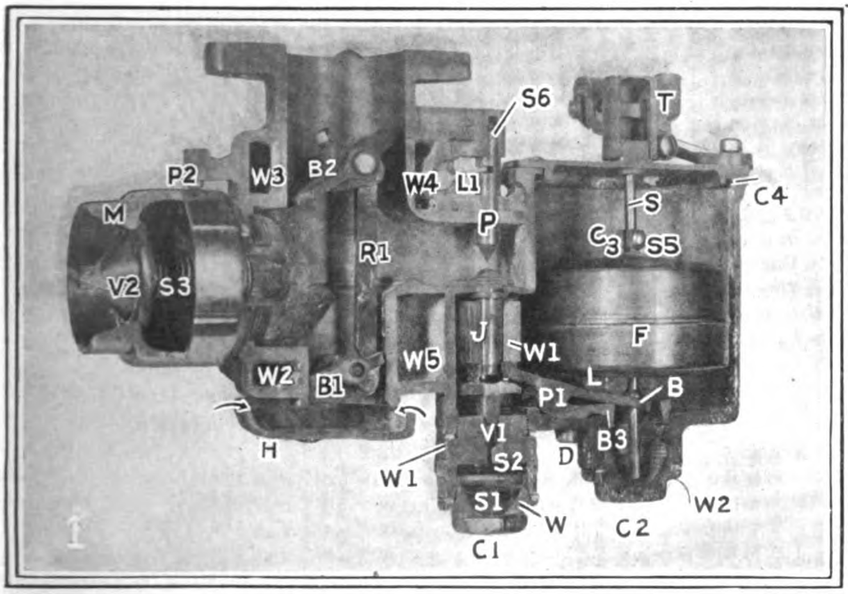
It is most essential that a car should be fitted with a good set of brakes, with adjustments that can be speedily effected. Brakeshoes of the type shown in Fig. 3, the surface of which was originally flat, but which has worn owing to the softness of the metal, are a cheap form and are a constant source of annoyance to the user. With the advent of the oxy-acetylene welding process it is no longer necessary to purchase a whole new shoe, as it can be seen from the Fig. 2 that the surface that contacts with the operating tongue is virtually as good as it was when turned out by the makers.

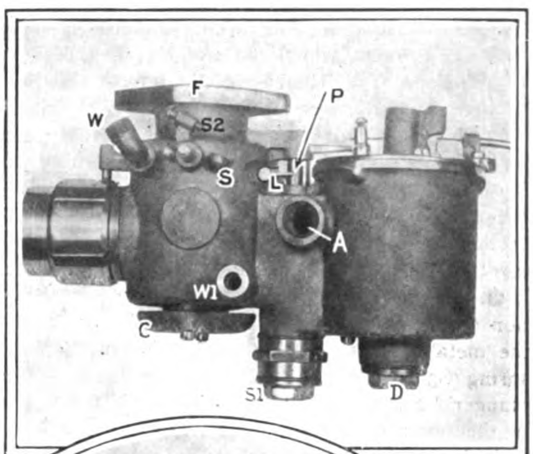
One has to be somewhat of a mechanic to improve what someone else has left undone. After the time that the unfortunate owner has changed this and altered that, he might have just as well paid a little more money in the first place, thereby saving himself a good deal of annoyance.

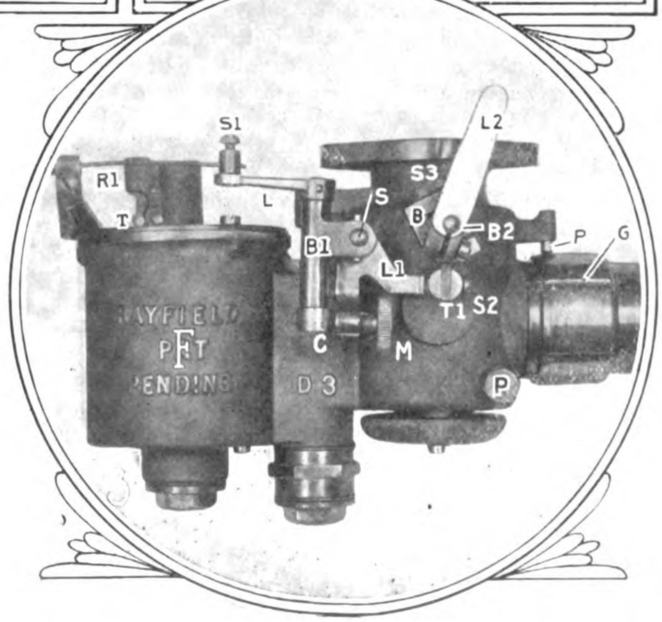
How to Study the Carbureter

Discussing the Details of Operation

It cannot be expected that a carbureter will work well every day all the year round under precisely the same adjustments when the atmospheric conditions vary in such wide degree. Every driver will have noticed how a car pulls better on some days than on others and how, when the car is new, the motor responds at once to a touch of the throttle, whereas when the motor has limbered up there is something still to be desired. In discussing these points the Rayfield is used as an illustration.







THE vagaries in the performance of the average carbureter are due to the fact that the adjustment of the gasoline to the air is better on some days than on others. This may not altogether be clear at first view, but when one considers the heat of a Summer's day and the intense cold of the Winter or the humidity that prevails on some days as compared to the crispness of others it must be apparent that gasoline will not always combine with the air in the same manner, and its differing volatility under various conditions will be understood.

In order to cope with the difficulties put before the motorist in his endeavor to obtain the maximum results under any condition, be they along the line of efficiency of the motor or minimum gasoline consumption, the Rayfield carbureter offers an example worthy of notice. The general principle of the carbureter follows along the broad lines of carbureter manufacture. Refinements have been introduced whereby through the turning of a milled screw or the pressing of a knob on the dash an alteration of the ratio of gasoline to air can be obtained.

It is proposed to show from the photograph of a carbureter that has been cut in two, as seen in Fig. 1, the relation of the various parts of the mechanism, and later from the two exterior views how these are operated and controlled. On the right-hand side of the illustration is the float chamber containing the float F, which is attached to a spindle S by means of a split clamp C3 and locked in position by means of a screw S5. If it is found necessary at any time to alter the gasoline level such an operation can be carried out in a very short space of time by removing the cover C4 which is held in place by three screws. The lower part of the float chamber is fitted with a plug which is removable if it is found necessary to drain the float chamber from time to time from any impurities, such as water, that may find their way inside. The lower end of the spindle S is formed in the shape of a ball which engages with a hole in the lever arm L, which is caused to rock on the pin P1 so that when the gasoline enters and fills the float chamber the needle valve V1 will drop and cover the orifice S2 through which the gasoline enters the carbureter in the first place. The lever and its support are carried on a bracket B3 held in place in the base of the float chamber by a screw D. To make the float chamber gasoline-tight there is a washer W2 interposed between the base and the cap C2.

Fig. 1—View of a Rayfield carbureter cut in half to show the co-relation of the various component parts

Fig. 2—Exterior view showing air intakes and general aspect

Fig. 3—Regulating device by which the flow of gasoline is varied

Below the seating S2 into which the needle valve fits there is a cap attached in a similar manner as C2 with a washer that contains a fine mesh wire gauze S1 and the connection for the gasoline feed screws into the base of C1. The needle valve seating is also removable, as the whole part S2 can be unscrewed from the main body. It will have been noticed that there are no weights in the float chamber, but this is carried in one piece with the needle valve V1, as seen at W1. The tip of the valve is made of steel and less susceptible to wear than brass or phosphor bronze. The weight is hollow and crossed drilled to allow the gasoline to pass from the float chamber to the spray nozzle or jet J. The jet is screwed into the part of the casting forming part of the mixing chamber and can be removed after the seating S2 has been removed, as it has a slot in the base for a screwdriver to get a purchase.

The quantity of the gasoline that is allowed to pass through the jet is controlled by an inverted plunger P with a conical end and the height of which is regulated by the small lever L1. One of the features of the Rayfield carbureter lies in the method of controlling this plunger. A spring S6 is placed in the recess above in order to insure that the plunger will return after being lifted by the lever. Without dealing at the moment with the operation of the plunger it might be mentioned that the higher the plunger is lifted the more gasoline will be allowed to pass into the mixing chamber.

Opposite the orifice of the jet there is provided a constant air intake, but it is not shown in the illustration; it can be seen, however, at A in Fig. 2. The mixing chamber is water-jacketed, the conduits through which the water passes being shown at W2, W3, W4 and W5. The base of the mixing chamber is open, being covered partially, however, by the cap H, air passing in as indicated by the arrows. Two butterfly valves situated in the mixing chamber control the main body of mixture at B2 that passes to the intake manifold, and the smaller butterfly B1 controlling the supplementary air which is required as the gasoline is increased by the automatic lifting of the plunger regulated by the throttle lever. On the left-hand side of the mixing chamber there is an automatic air valve that works in accordance with the suction of the motor. The valve is shown at V2 with a section of the metal cut away to show the nature of the valve and the spring S3 that holds it on its seat at slow speeds. A spring plunger P2 is situated above the valve and registers in slots cut in the outer casing M. The adjustment of the valve is controlled by screwing the casing M one way or the other, which has the effect of bringing the seat on which the valve rests nearer or farther away from the main body of the carbureter, thereby increasing or decreasing the tension of the tension spring.

Having thus dealt with the internal organs, it remains to show how the adjustments are effected and how the relation of gasoline to air is altered to suit certain conditions.

Just what effect the extra air valve has over the carburetion can be summed up in a few words. In order to equalize the flow of gasoline and air it must be remembered that as the suction of the motor increases with a corresponding increase of speed the capillary attraction on the jet is increased and more gasoline is caused to spray through the orifice of the jet. The air, however, does not increase in the same proportion, therefore the automatic air valve is employed so that with the increase of suction the spring will be overcome and allow additional air to pass in and mingle with the gasoline.

It has already been shown how the plunger P in Fig. 1 is formed and how if this is raised or lowered the quantity of gasoline that will pass through the orifice will be increased or decreased respectively.

Fig. 2 shows the lever L and the part of the plunger that is exterior of the carbureter. The lever L is caused to move up and down carrying the plunger with it. The constant air intake is shown at A and the water connections for heating the mixing chamber to assist evaporation and prevent condensation are shown at W and W1.

The adjustments are shown in Fig. 3. The small shaft S is connected to the lever L in Fig. 2 and therefore to cause the plunger to rise or drop is a matter of causing the shaft S to rotate. The tube C extends to the dash and terminates in a bracket with a push knob. This knob is attached to the extension of the wire R1, which in turn is attached to the lever L by the set screw S1. If the knob on the dash is pushed in or pulled out the lever arm will be moved to and fro, and being as it is connected by a shaft inside the bracket B1 to the cam C, and rotation will cause the cam to ride on the set screw M and so turn the shaft S which will move the plunger over the jet.

This offers a means of increasing the amount of gasoline for starting purposes and fixes the slow-speed setting. The limit of travel in this direction is regulated by the set screw S2 in Fig. 2. The lever L1 in Fig. 3 carries at one end a slot with a tongue held in place by the screw S2. The tongue T1 is in contact with the curved block B and as the throttle lever L2 is moved the tongue will ride on the block B and cause the lever L1 to move and so turn the shaft S, thereby raising the plunger. The butterfly valve shaft is attached to the block B2 and the adjustment of the lever L1 in relation to the throttle is regulated by the screw S3, which causes the block B to press down on the tongue or recede from it. The plug is connected with the water circuit and should be unscrewed to let the water out of the jacket whenever it is found desirable to let the water out of the motor and radiator in the case of frost, otherwise the water may expand and burst the carbureter casting.

When Judgment Whispers Don't

DON'T imagine that taking care of an automobile is a matter less serious than the work of nursing a child; trouble will come if either is neglected.

DON'T believe that the noise of a motor is of lesser significance to the well-being of the car than the whine of the baby is an indication of an ill-balanced digestion.

DON'T overlook the fact that oil is great stuff in putting deranged organisms and mechanisms into order; a good dose of lubricating oil will benefit the car much as castor oil will silence the suffering baby.

DON'T misunderstand the desire of the motor for gasoline; it delivers its useful work in just the proportion as it drinks up the stuff.

DON'T entertain the idea that a good ignition system is less important than a sufficient supply of gas; the stimulant must be burned to make the car move.

DON'T monkey with the ignition system of your car; it ought to be below your dignity to play with the sundries.

DON'T be impressed with the self-conscious air of the chauffeur adjusting the carbureter; he may be unable to restore the good adjustment which he spoils.

DON'T underestimate the value of the man who goes about his work on the automobile without trying to show off and to put up a bluff.

DON'T tell your friends about the virtues of your chauffeur and then object when the fellow demands a raise; someone might have handed him the tip.

DON'T frown when you pay for the maintenance of your automobile: an automobile, if rightly applied, more than pays for the cost of buying and keeping it.

DON'T think that the only way in which an automobile pays is in cash coin; pure atmospheric air, moving at a speed of 20 miles or so, is more useful than gold and, therefore, it has to be paid for.

DON'T forget that the refreshment brought about by a 20-mile ride enjoyed every evening will stretch your lifetime to three-score and ten years.

DON'T pour gasoline through a dirty funnel. If it has been standing for a while, clean it out.

Peeps Thro' Goggles at Distant Lands

What the Foreigners Are Doing in Automobiling

Siam's King's official physician is provided with an automobile—British discussing visible sign-posts—London's Fire Brigade being rapidly motorized—Building cars to measure—Imports of gasoline into the United Kingdom—Coronation Durbar in Delhi brings demand for automobiles.

FAR-OFF, benighted Siam is stepping out into the spotlight, so far as the adoption of automobiles for public service is concerned. The latest example of modern enterprise along these lines is the purchase of a 10-horsepower motor car for use by the Medical Officer of the Bangkok, Siam, Board of Health, Dr. Highet, who is also physician to the King of Siam. He will employ the automobile extensively about the country, since his professional duties are calling for a wide circle of work.

In dealing with the scheme for providing a unification of the erection and maintenance of warning signs in England for the benefit of automobilists, the British Roads Improvement Association has considered the question of the visibility of the posts carrying the signs at night. The scheme involves a series of five sign posts, each differing in color, and so painted as to be seen after nightfall.

London's automobile Fire Brigade has met the expectations of even the most sanguine promoters of the new plan. The force of this statement will appear when it is said that London has decided to discard horse-drawn fire engines and horse carts altogether. The Finance Committee of the London County Council having the preparatory matters in hand, estimate the cost of the complete conversion of the Fire Brigade equipment—more than 210 appliances—at $1,050,000. The Treasury will be asked to sanction a period of ten years for the repayment of so much of the expenditure as would be considered equal to the net addition to the capital value of the Fire Brigade's plant.

Certain English automobilists are arguing with the aim to bring about car-building to accommodate individual requirements, after the manner that one would order his tailor to make him a suit of clothes. Special attention is called to the individual requirements in the distance between the seat and the steering-wheel. One motorist who confesses to be "of generous proportions" bewails the fact that not he alone, but many other "motorists of huge anatomical proportions" frequently are forced to subject themselves to painful contortions in order to get safely ensconced behind the wheel; while small men are seen steering with the wheel in an awkward position, much too high for them. The complainants seek to have all of these errors of construction changed.

The United Kingdom imported 30,000,000 gallons of gasoline during the first six months of the present year, ending the 30th of June. Of this amount, the bulk came from the North American oil fields. Only 10,000,000 gallons was sent from the Far East, the quantity falling below the supply shipped from that section of the world into England during 1909 and 1910—years in which the American supply to England was very low. There were 3,000,000 gallons of Far East imports into Holland, which amount was reshipped to England, during the first six months of this year. This product came from the Shell Royal Dutch fields. Russia gained considerably over previous years, her supply of Grosny gasoline into England amounting to 5,000,000 gallons.

The Far East is raising a loud voice in the call for the automobile. The Indian Government is manifesting a spirited interest in this respect, having just ordered thirty English-made, 15-horsepower, four-cylinder motor cars for official use during the forthcoming Coronation Durbar to be held in Delhi on the occasion of the visit of their Majesties, King George V and Queen Mary.

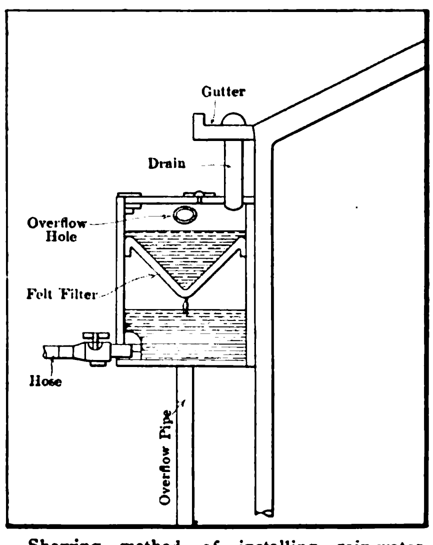
Soft Water for Radiators

The thoughtful garage owner and motorist can have the very best water for the radiator by the installation of a device for catching the rain water from the roof of the garage and keeping it bottled up so that it is handy at any time. The water can be used not only for the radiator, but also in washing the finely finished parts of the body.

THE virtues of soft water for the automobile radiator are well known and recognized by all those who have any knowledge whatever of the preservation of metallic surfaces which are in contact with water. Ordinary city hydrant water always contains a number of impurities which are extremely injurious to metal even if they are present in very small quantities, the greatest amount of damage, perhaps, being caused by the carbonic acid which is present to a greater or less extent in our city water. This acid is very active when heated.

The hardness of water is determined by the amount of lime or magnesia it contains which have the ability to decompose soap. This faculty provides a means of measuring the hardness of the water and by chemical relations involved determines the purity. Rain water lacks to a great degree the corroding elements and hence is valuable for use in automobile radiators. The accompanying wax illustration shows a method whereby the rain water may be caught from the roof of the garage, filtered and kept for use at any time.

If the tank is made large enough the water may be used in washing the more finely finished parts of the body, thereby preserving the delicate finish for a much longer time than if the ordinary hydrant water were used. The water flows from the roof into the upper part of the filter-tank and strains to the lower part, passing through a piece of felt which effectually filters the water. The felt may be replaced by a fine wire-gauze strainer if desired. In case of a superabundance of water, the excess will drain to the ground by means of the overflow pipe and hole in the upper part of the tank. This should be led to a spot where it will not collect in a pool, and soak into the walls.



Showing method of installing rain-water tank so as to take the water from the garage roof.

The Heat Losses of Cooling

Enforced Radiation a Necessary Evil in Any Engine

Greatest among the sources of loss of thermal efficiency stands the cooling process, which, although necessary, can, by an intelligent manipulation born of a knowledge of the basic principles involved, be made to perform its work in the most economical manner possible.

ALONG with all the other ideas of obtaining "something for nothing" in a mechanical way that of producing an engine without some process of cooling, with its consequent loss of thermal potency, has long passed away. The flow of heat through a body, such, for instance, as the walls of the cylinder of a motor, is a function of the time of the process, the area of the surface involved, the difference in temperature of the opposite surfaces of the body, the conductivity and the thickness. The thickness, in so far as the purpose of this article is concerned, may be neglected. A knowledge of these facts is of use if taken with the other phenomena of the gas engine cycle and used to secure the utmost efficiency from the engine without sacrificing certain necessary features in construction.

Since the longer the cooling process is carried on for each charge brought into the cylinder, the more heat (which has been abstracted from that charge) will be thrown away by the radiator, it is evident that the best conditions obtain when the exploding charge is submitted to the cooling influence of the cylinder walls for the shortest length of time. This means that more charges must be burned per minute in order to have each charge acted upon for a less amount of time and also, since, as we have stated, the radiation is a function of the time, to allow a less amount of heat to pass through the walls. Evidently the more explosions per minute the higher the piston speed, which indicates that the greater the number of revolutions per minute at which the motor is run the lesser the amount of heat lost through the cooling medium from a per-horsepower standpoint.

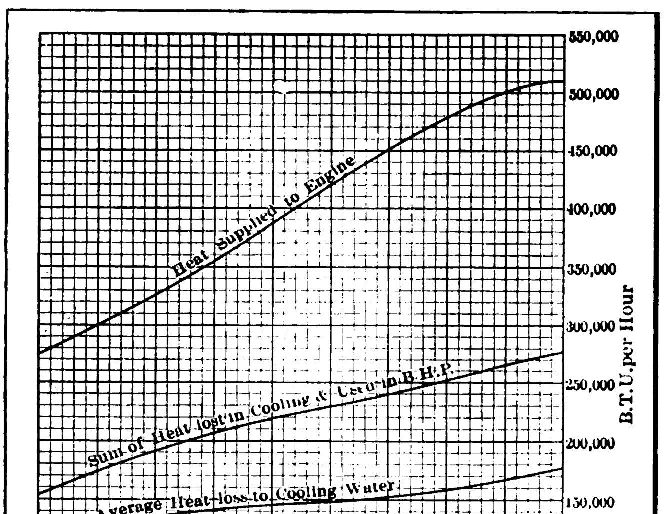


Fig. 1—Showing the amount of heat lost in the cooling fluid as compared with that given up in useful work. (B. H. P.) The distance between the two upper curves gives the heat lost through other causes

The area of the metal exposed to the burning charge is directly dependent upon the bore and stroke, with the exception of the irregularities in the shape of the combustion space due to ignition system openings and valves. Hence the factor of area is determined very closely in the primary design of the motor. It serves to illustrate, however, that there is a greater loss, per horsepower, of thermal efficiency due to cooling in a large engine cylinder than in the smaller high-speed type. Combining the two functions of exposure, time and area, it will be seen that the least amount of heat lost is under the condition of having the least area exposed per unit of time per explosion. This again brings in the condition of high speeds for the reduction of the loss of thermal efficiency due to cooling.

In order to cut down the heat extracted by the cooling fluid from the burning gases the difference in temperature between the inner and outer faces of the cylinder walls must be as small as possible. Since the heat of combustion is fixed and definite, the nearness of the temperature of the cooling water side of the cylinder wall to that of the combustion side will be determined by the heat of the cooling water, the hotter this is the less the difference in temperature between the two faces. The cooling water must therefore be allowed to run as hot as practical limits will permit. The heat of the cooling water is regulated by either the amount of water passing through the jackets in a given time or by the rapidity of the circulation. Good practice on level ground is to have the cooling water at about 180 degrees Fahrenheit; this leaves a margin before reaching the boiling point of 32 degrees, so that in climbing a long steep hill where the motor will heat up owing to the open throttle and late spark there will not be such a tendency to overheat the water.

The remaining factor of conductivity is negligible in this discussion, as it is constant for all the standard radiators in use and may be regarded as a fixed quantity.

The set of curves given in Fig. 1 will illustrate graphically the amount of heat lost in cooling in the average motor of good design running under mean conditions. The four curves show the thermal equivalent of the brake horsepower, the average heat lost per hour through the medium of the cooling water, the sum of the heat lost in cooling and used in producing the brake horsepower and the total heat supplied to the engine with the fuel. Since the third-mentioned curve is the sum of the heat lost in the water and that used in brake or useful horsepower, the distance between this and the top curve of heat supplied with the fuel will represent the heat losses by other means than by the cooling water, that is through the exhaust and by friction. An examination of this set of curves will show that the heat lost to the cooling water is more than double that used in producing useful work at the lower number of revolutions, while the ratio grows less as the revolutions become higher and the cooling water is exposed to the heat of each explosion for a less amount of time.

Although the cooling fluid carries off much of the heat in the cylinder walls it must not be supposed that the walls are ever of the same temperature as the cooling fluid even at the coolest part of the cycle, for the remaining dead gases after the exhaust are of very high temperature. On the suction stroke this temperature is reduced by the incoming mixture, but even then the walls are hot enough to contribute toward heating the new charge. It would be impossible for the walls to give up all the heat absorbed by them during each explosion stroke in so short a time as that which marks the interval between these operations. After the engine has been running a while at a regular speed a rythmic wave motion of heat rises and falls in the cylinder and cylinder walls. The difference in temperature between the cooling water and the metal of the cylinder walls must, even in the most favorable conditions, be 55 degrees and in very large cylinders even more. Referring to the curves in Fig. 2, the rapidity of rise of the curve of B. t. u. in cooling water referred to piston displacement will be noticed. This is mainly due to the greater temperature difference between the water and the cylinder walls.

The shape of the combustion and expansion space has a very large influence on the number of heat units lost in cooling. The expansion space is of necessity cylindrical, while the ideal combustion space is a smooth and unbroken hemisphere. Omitting the question of structural strength entirely and looking at the matter solely from a cooling standpoint, it is seen that the reduction of exposed area per cubic inch of combustion space is as great as possible in the dome shape of head and since the amount of cooling is a function of the area exposed the advantages of this type of head for the combustion space is evident. Since it is impossible to get away from the cylindrical form of expansion chamber; cylinders are designed so that the engine will be suitable for the work required of it and yet give the least area relatively to the volume of the combustion space. We can find the relation of stroke to bore which will give the condition when the relative exposed area is least by solving the equation of the volume for a minimum in terms of the surface. Let L equal the length of stroke, D the diameter of the cylinder, V the necessary designed volume, S the exposed surface.

$$V = \frac{\pi D^2 L}{4} \qquad (1)$$

$$S = \pi D L + \frac{2 \pi D^2}{4} = \frac{4V}{D} + \frac{\pi D^2}{2} \qquad (2)$$

Let

$$\frac{dS}{dD} = 0 \quad \frac{dS}{dD} = -\frac{4V}{D^2} + \pi D = 0, \pi D = \frac{4V}{D^2},$$

therefore $D = \sqrt[3]{\frac{4V}{\pi}}$ (3)

But

$$L = \frac{4V}{\pi D^2} \text{ from (1) and } D = \sqrt[3]{\frac{4V}{\pi}} \text{ substituting } D = L. \qquad (4)$$

That is, the surface of a cylinder of given volume is least when the diameter equals the length. Other practical factors entering in, however, make it better to have a different relation of bore to stroke than that just deduced.

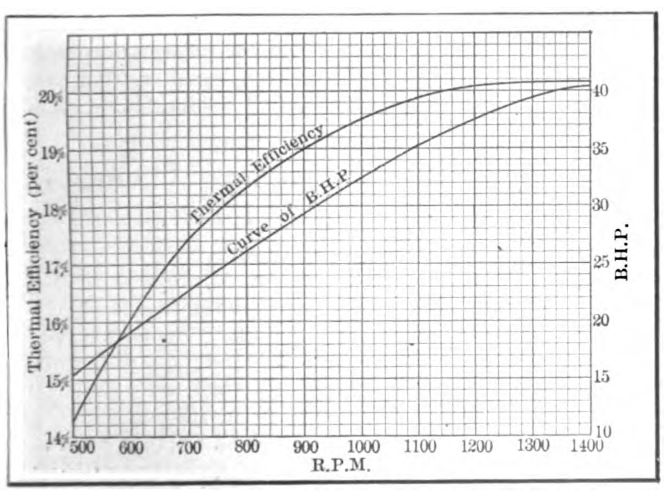

Fig. 3—Curves of B.h.p. and thermal efficiency plotted on the basis of revolutions per minute

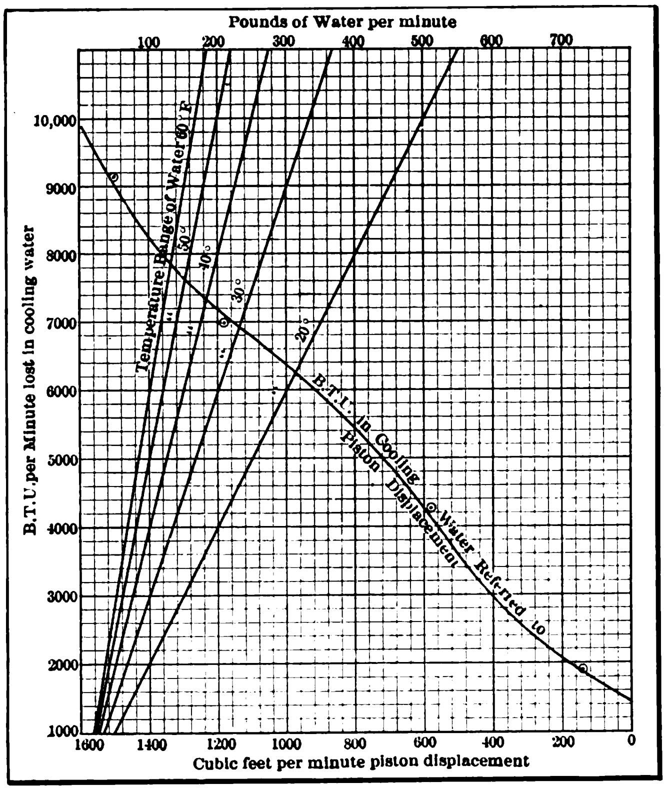

Fig. 2—Curves of B.t.u. in cooling water and temperature ranges. These curves are read vertically from the base up to the curve of B.t.u. in the cooling water, then horizontally to the temperature range curves

The thermal efficiency is affected by many conditions after the engine has reached 1,200 or 1,300 revolutions per minute and, as will be seen in Fig. 3, the slope of the curve, which measures its rate of increase, will fall off appreciably. The curve of brake horsepower will also start to fall off as the revolutions per minute become excessive and the difficulties of overcoming the inertia of gases and reciprocating parts of the engine increase. Fig. 3 was taken from tests on a 36-horsepower motor and is fairly representative of an egnine of that rating. The engine was six-cylinder, four-cycle, having a bore of 3 15-16 inches and a stroke of 4 3-4 inches. The rating is according to the A. L. A. M. formula.

Loss of Power in Motor

Where fiber gears are used to drive the camshaft an evasive squeak will often be heard which can be traced at times to the fiber gears which have swelled so that they no longer fit their driving pinions. The remedy is not hard to apply and will be found to be a success.

SOMETIMES the motor will not be developing its usual power and an unusual scraping sound will be heard. This trouble often occurs with engines having fiber gears to drive the camshafts, which have been in service for some length of time. The cause is the swelling of the gear wheels due to the absorption of the oil, the gears expanding and meshing too tightly with the steel driving pinions, or, at the same time, swelling laterally and rubbing against the casing. This will heat the camshaft bearings.

The remedy lies in replacing the fiber gears or in recutting the teeth of the gears and reducing the pinion to normal thickness by planning or turning in an engine lathe.

A HABIT that can be readily acquired by a new driver is that of throwing out the clutch when turning a sharp curve at any speed. Severe torsional strains are averted and tires saved by this precaution.

What Some Subscribers Want to Know

Increases the Power of His Engine Thirty Per Cent.

Editor THE AUTOMOBILE:

[2,779]—The accompanying sketch (Fig. 1) illustrates a change I made in my automobile engine which increased the power 30 per cent.; thinking the same may interest some of your readers I am sending it to you. H. W. BARTOL.

Philadelphia, Pa.

Clutch Jerks on High Speed

Editor THE AUTOMOBILE:

[2,780]—I am a subscriber to your magazine and would like to know what is the trouble with the cone clutch on my car. When I put the clutch in on high speed it does not seem to take hold; it jerks and pounds, whereas when I hold it half in only it does not pound so much. I have oiled it and have wiped off the oil, but it does not seem to have any effect. Would you give me some idea of the trouble? DECORATOR.

Sarnia, Ont., Canada.

The symptoms of your trouble seem to point to either one of two things. Either the leather has become lifeless and lost all its elasticity or the transmission and the flywheel are no longer in proper alignment.

May Be Due to a Variety of Causes

Editor THE AUTOMOBILE:

[2,781]—Will you kindly inform me through your columns to what cause the following may be due: A friend of mine has a four-cylinder machine which has been run about 10,000 miles. Whenever the throttle is wide open all the cylinders work fine, but when the throttle is closed only two cylinders work. If you could give me any information on this matter I would greatly appreciate the same.

FRANK MOSHER.

Roberts, Ill.

Owing to the lack of detailed information at hand it is impossible to specificize an answer. The trouble may be due to

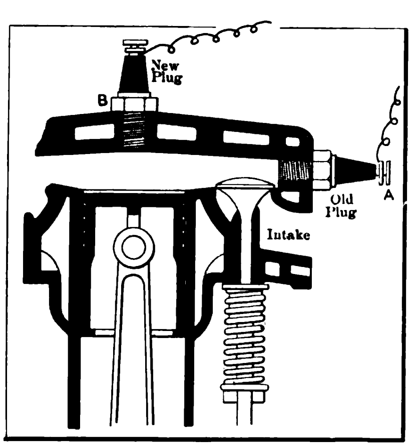

Fig. 1—Illustrating the manner in which a reader increased the power of his motor by 30 per cent.

several causes which may be searched for in the following order: First, test for a spark at all the cylinders while the engine is running at low speed; if this test shows that the current is satisfactory try closing the gaps between the points on the spark plugs in the missing cylinders. If the current is not satisfactory the trouble might lie in a dirty magneto distributor. Having eliminated the ignition system as being the source of trouble there remains the gas supplied to the cylinder which may be the cause of trouble. Examine the intake line at all parts between the carbureter and the intake manifold of the engine for leaks, clean the dirt out of the carbureter and if the disturbing element is not located as one of these, the throttle

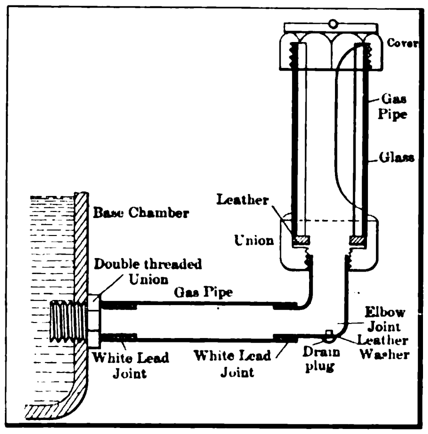

Fig. 2—Method of making and attaching an oil level gauge to the base chamber with standard pipe fittings

lever is apt to close the valve too much, thereby supplying very little gas at low speeds.

Wants to Install Oil Level Gauge on Crankcase

Editor THE AUTOMOBILE:

[2,782]—I have a car which is lubricated by the splash system. The oil reservoir is located in the lower part of the crankcase and carries the whole supply of oil for the engine. At present it is impossible to tell how much oil there is in the crankcase or if the pump which takes the oil from the reservoir and places it in the splash chambers is working or not, as there is no sight feed on the motor nor is there a level gauge. Will you kindly tell me how to go about installing either a level gauge or some other device to ascertain the amount of oil present in the crankcase at any time? I thank you in advance for the information which I am sure will be of general interest. R. F. G.

San Antonio, Texas.

A very good level gauge may be attached to the average crankcase with very little expense since it can be made up of

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their automobile troubles, stating them briefly, on one side of the paper only, giving as clear a diagnosis as possible in each case, and a sketch, even though it may be rough, for the purpose of aiding the Editor to understand the nature of the difficulty. Each letter will be answered in these columns in the order of its receipt. The name and address of the subscriber must be given, as evidence of good faith.

standard plumbing or gas fitting parts. As shown in Fig. 2, it will be made up of a double-threaded union, a piece of gas pipe, an elbow and the other parts illustrated. If the specifications in the sketch are carried out a very neat and satisfactory job should be the result.

Hears a Mysterious Rattle Beneath Car

Editor THE AUTOMOBILE:

[2,783]—I have noticed a rattling sound some place in the car and have been unable to locate it. The noise seems to come from some place in the transmission or differentials; it is not a constant rattle, but is only noticeable on first and second gears, and it seems as though the car only rattles in going around sharp corners or up an uneven grade. The machine has only been run about 800 miles and has been well oiled and greased at all times. I sometimes speed the car up on the lower gears and notice that the rattle will cease. If you will give me any information through your columns as to the method of locating and remedying the trouble, same will be greatly appreciated.

A SUBSCRIBER.

Selmer, Tenn.

It is difficult to accurately locate the seat of trouble from the information at hand; we would suggest, however, that you examine the internal floating brake bands.

Attaching Blame Where It Does Not Belong

Editor THE AUTOMOBILE:

[2,784]—In THE AUTOMOBILE of May 11 there is an article under the head of "The Tempering of Steels." I tried the salt bath on a cold chisel and find that it is not right, making the steel too soft.

Could you give me through your paper a method by which an amateur could arrive at a fair degree of accuracy in the matter of tempering cold chisels? The average thing that is sold in tool kits for a cold

What Other Subscribers Have to Say

The Editor invites owners and drivers of automobiles who are subscribers to THE AUTOMOBILE to communicate their personal experiences for publication in these columns for the worthy purpose of aiding brother automobilists who may be in need of just the information that this process will afford. Communications should be brief, on one side of the paper only, and clearly put, including a rough sketch when it is possible to do so, and the name and address of the writer should be given as evidence of good faith.

chisel is far from what the name implies. Most of them break with the first blow.

Perley, Minn. J. E. RICHARDS.

In trying the salt bath in the process of tempering a cold chisel you very improperly blame the bath instead of questioning the quality of the material in the chisel. If the cold chisel is composed of steel including from 60 to 80 points of carbon it will take temper if it is heated to a cherry-red and quenched in either water or a salt bath. It is more than likely that the cold chisel used in your test is some cheap imitation holding carbon below 20 points.

One reason why cold chisels break so readily as referred to by you lies in the fact that they are not "drawn" after they are tempered. The right way to proceed is to heat the chisel to a full cherry-red, quench it in salt water, and thereafter draw the temper of the steel to perhaps a "straw" color.

Installing a Strainer and Cover on Oil Tank

Editor THE AUTOMOBILE:

[2,785]—I have at my disposal a small shop in which I make little repairs on my machine as they happen to be necessary. The car is rather old fashioned and is not equipped with a very suitable cover on the oil tank. There is no strainer and I am very liable to get foreign matter into the tank. Could you tell me of an easy method of making a cover which will contain a strainer?

READER.

Bath, Me.

The accompanying cut (Fig. 3) illustrates one method of making a cover and strainer for an oil tank, which will be found to be satisfactory and easy to make. A threaded ring is soldered into the tank as shown. A piece of tubing fits into this ring and supports the strainer, which is held in place by the tube, which is turned down as shown. The cover fits over the filler opening and provides a dust-tight seal.

Fooling Prospective Chauffeurs

Editor THE AUTOMOBILE:

[2,786]—In taking my examination for a chauffeur's license at the secretary's office I was given the following question: Name several methods of running an engine on compression when the low gear is engaged. I could only answer in one way. Will you kindly tell me other methods of doing this? G. B. M., JR.

Brooklyn, N. Y.

Unconventional Type of Differential

Editor THE AUTOMOBILE:

[2,787]—I understand that there is a French car made that used a type of differential in the live rear axle different from the conventional, inasmuch as the sides of the bevel pinions are approximately the same. Give an explanation of the workings of this type of differential.

Brooklyn, N. Y. DESIGNER.

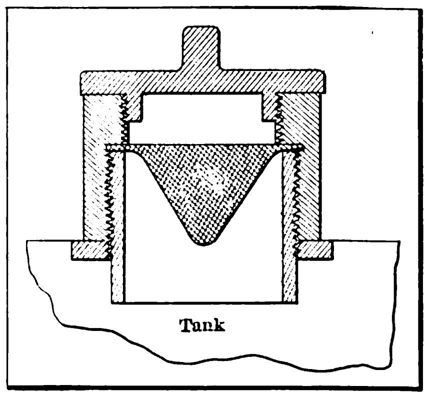

Fig. 3—Showing a home-made oil-tank cover and filler cap containing a strainer to remove the foreign matter from the oil

The type of differential you probably allude to will be seen in Fig. 4. The driving shaft A taking the power from the motor through the transmission is fitted with load and thrust bearings, being an integral part of the gear wheel B. An intermediary shaft fitted with annular load and ball thrust bearings carries two pinions. The bevel gear wheel C meshes with B and transmits the power to the gear wheel D, which is keyed to the shaft. The straight pinion E is bolted to the boss F, which contains a set of star pinions. The jackshafts, which have square ends, fit into corresponding holes.

Wants a Little Tire Information

Editor THE AUTOMOBILE:

[2,788]—I am taking the liberty of asking you a question in regard to a tire for my machine. Would I require a smaller tube for the tire if I used a liner? I use 30 x 3 1-2 inch tires and would like to know if it would be right to get a smaller tube if I should use the liner, or if the same size would be suitable. Any information would be appreciated. ED. C. BATES.

Clarksville, Tenn.

The same size tube would be required whether you used the liner or not.

Wants Information with Reference to 1912 Specifications

Editor THE AUTOMOBILE:

[2,789]—Can you give me any information in regard to the specifications of the 1912 Cadillac? Will they have a four-speed transmission and will they have a 4 1-2 x 5 motor? Will the wheelbase be longer?

Corvallis, Ore. WALTER H. KLINE.

Up to the present moment the company has not made any announcement as to its 1912 models, and no doubt you will be able to get the information you desire from the factory direct.

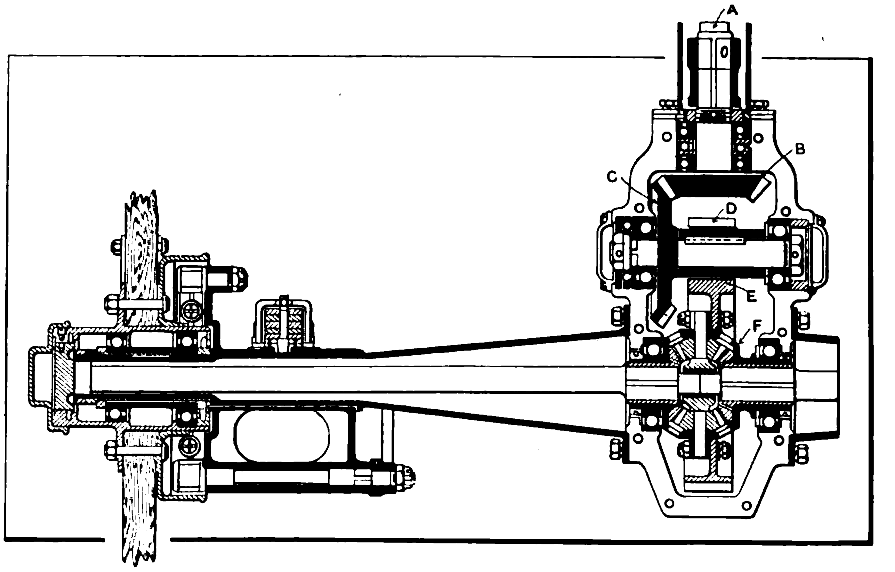

Fig. 4—Section through a live rear axle showing the method of operating the driving pinion by straight tooth gears

Meeting Recurring Troubles

Presenting a Series of the Most Probable Cases

A series of co-related short stories, accompanied by diagrams and characteristic illustrations, indicating the nature of the troubles that are most likely to happen to automobiles, discussing their causes and effects, all for the purpose of arriving at a remedy. It is the aim, for the most part, to show how these troubles may be permanently remedied, and as a secondary enterprise it is indicated how the automobilist can make a temporary repair, thereby enabling him to defer the making of a permanent repair until a convenient time arrives.

THE BUTTERFLY VALVE.—The throttle valve is the valve which, in conjunction with the spark timer, governs the speed of the car and relatively the amount of fuel it consumes. This valve is of necessity positive in action and must give a wide range in the size opening of the inlet pipe. There are two types of throttle valves which are in general use at the present day; they are the butterfly valve, as shown in Fig. 1, and the plug type, which is not so often used on motor cars. The butterfly type of valve is arranged so that a rotating metallic flap (the butterfly), which is actuated by a spindle, can be turned so that it shuts the pipe completely and thereby throttles the inlet pipe. The opening is a maximum when the butterfly is parallel with the pipe. In this case the opening is not obstructed except by the thin metal disk which forms the valve and which is so narrow that the flowing gases are not checked to any appreciable extent. Generally the throttle valve forms a part of the carbureter and the spindle is continued up a distance above the inlet pipe to allow room for a governing lever. To this is attached the throttling mechanism, which, of course, is controlled from the steering wheel throttle lever.

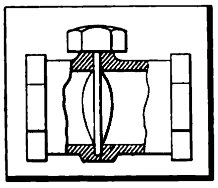

Fig. 1—Illustrating a common form of butterfly throttle valve. The valve is often punctured by a small hole so that the engine will just turn over when the valve is closed

The plug type of throttle valve is found for the most part on steam apparatus. It is a cylinder or cone in which there are either a number of slots or in other cases one. The cylinder is hollow and can turn on its axis or can slide longitudinally. The slot is arranged so that as much of it as is needed can be exposed, allowing the fluid to pass through. The opening is a maximum when the whole slot is exposed or a minimum when the slot is behind the bushing. The advantage of this type of valve is the great nicety to which it may be adjusted. This advantage is possessed to a great degree by the butterfly type as well.

CARE OF STUFFING BOXES.—No matter where the mechanician's field of activity is located, whether in a garage equipped with machinery or in the country home, where the machinery of the garage is used to pump the water and perhaps light the house, he is going to strike at some time or another a stuffing box which needs repacking. The average stuffing box will hold its packing in a water-tight or gas-tight condition for a great length of time before it needs replacing. When the time does come to replace the packing it is not as a general rule necessary to send the box to a repairman, but the work can be done at the garage by anyone who understands the construction of these devices. The accompanying cut (Fig. 2) gives the usual form in which the stuffing boxes are made. The cover is always made removable and the packing can be taken out after the cover has been removed, new packing can then be placed in position. The packing used will, of course, depend upon the nature of the service to which the stuffing box is to be adapted. A leaking stuffing box does not always have to be repacked, as there is an easy method of adjustment to tighten the pressure on the packing, which will stop leakage if the material used for packing is in fair condition. In the type shown in the illuustration, if the nuts on the ends of the bolts are tightened the packing will be squeezed against the shaft and the leakage will generally be stopped. In tightening the adjustment of a packing box the nuts should not be tightened any more than is required for a non-leaking joint, for if this is done a large amount of friction will ensue which helps to cut down the efficiency of the machine besides heating the bearing and wearing the parts.

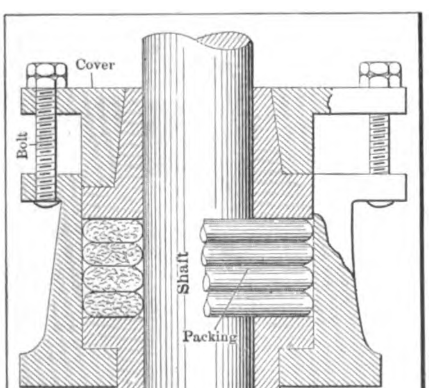

Fig. 2—Simple packing or stuffing box which may be adjusted by the tension on the bolts

SHEET METAL JOINTS.—There are two types of sheet metal joints which are in general use, they are the lap joint and the butt. To resist a pull of any amount the butt joint possesses the greater strength, as in order to fail two rows of rivets must be sheared or the butt strap must fail by tension. An examination of Fig. 3 will show the relative merits of the two systems of making joints and give an idea of the comparative strengths of the two. The joint most used in automobile practice, in such places as the channel automobile frames, is the butt joint. This type of joint may be welded or held in place with a butt strap, as the illustration shows. Very often in heavy work there are two butt straps employed which give a large amount of additional strength, in this case the rivetting is either double or triple. It is not used in automobile work, however, as there are no requirements for it.

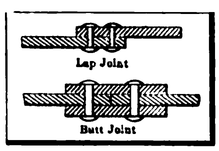

Fig. 3—Showing a double rivetted lap joint and a double strapped butt joint—two common forms of sheet metal joints

RELATIONS BETWEEN TIRE PRESSURE AND FLEXURE.—The following tables show the amount of flexure of the tires taken promiscuously, as compared with the size of the tire at the top:

Tests on Rear Wheel of Empty Seven-Passenger, Six-Cylinder Touring Car Fitted with 37 x 5 Plain Tread Tires.

Pressure in pounds per square inch	Measurement of tire on top in inches	Measurement of tire at bottom in inches
105	4 9-16	4 1-16
100	......	4
90	......	3 7-8
80	......	3 13-16
70	......	3 25-32
60	......	3 3-4
55	4 1-2	3 3-4
50	......	3 11-16
40	......	3 5-8
30	......	3 7-16
20	......	3 1-8
14.7	......	2 13-16

The extreme widths of the tire at the pressure that the tire was found to contain, viz., 55 pounds, measured with a pair of calipers, were as follows: Top, 5 5-16 inches; side, 5 1-4 inches; bottom, 4 3-4 inches.

Tests on Front and Rear Wheels of Limousine Fitted with 36 x 4 1-2 Tires.

Pressure in pounds per square inch	Front Tire Top	Front Tire Bottom	Rear Tire Top	Rear Tire Bottom
90	4 1-16	3 3-8	4 1-16	3 3-8
80	......	3 1-4	......	3 5-16
70	......	3 7-32	......	3 1-4
60	......	3 3-16	......	3 3-16
50	......	3 1-8	......	3 1-16
40	......	......	......	2 7-8
30	......	......	......	2 5-8
20	......	......	......	2 3-16
14.7	......	......	......	1 13-16

BEST WAY TO "SET OUT" PISTON RINGS.—Cast-iron piston rings may be set out by means of a pien hammer, just as was formerly done with steel steam rings. The only thing is that the work must be done more slowly and more carefully. There are machines on the market in which the rings are turned concentric, and then made elastic enough to spring out and hold against the cylinder walls by hand-piening on one side of the ring. The number of examples of this are few in America, but a number of French car makers use it.

GEARS AND PINIONS MUST HAVE DURABILITY.—The great factor in the design of involute gears and pinions is the angle of obliquity or pressure. This angle can not be made standard for all sizes of gears as for instance in using a pinion of ten teeth with the common pressure angle of 14½ degrees the flanks of the teeth will be undercut too much and the tooth materially weakened. Take for example Fig. 4, which shows a segment of a gear of ten teeth, four diametral pitch. The angle of obliquity causes the teeth of this pinion to be undercut to such a degree that its durability would be considerably shortened, hence gears that are to do heavy work may require a greater angle of pressure than 14½ degrees if they are to run with a pinion of less than 12 teeth.

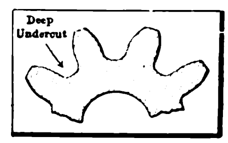

Fig. 4—Showing gear with excessive undercut

In the choice of an angle of pressure some idea of the correct angle may be obtained from Fig. 5, which is taken from a ten-tooth gear, four pitch, the angle of pressure being 22½ degrees. The greater strength of the gears in this figure is readily seen. In any case the angle can not be much more than 32 degrees and have the addendum of the teeth, the ordinary height which is equal to one of the diameter pitches or the module.

LIQUID IN MIXTURE IS MISCHIEVOUS.—Gasoline as light as octane will vaporize sufficiently well in the carbureter and the intake line to justify its use in automobile work. The heavier products, however, vaporize but poorly and cause the most annoying crankiness on the part of the motor due to the deposit of carbon, which can be so often traced to these fuels. Octane is just about on the border line and a gasoline which contained any quantity of it would be a very poor quality indeed, a trace of it will be found to be present as a rule though and if it is not in too large quantities it will vaporize sufficiently well to allow it to just pass.

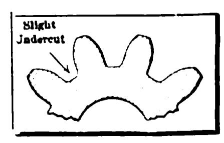

Fig. 5—Segment of 10-tooth, 4-pitch gear

The accompanying cut, Fig. 6, will show a common form of trap which may be placed in the intake line. This trap will catch the liquid globules as they pass through the pipe and drain them into the recess which forms the lower part of the trap. The liquid strikes the baffle plate, which protrudes into the intake pipe and fall through the hole into the retainer located below. If the liquid gasoline should pass into the cylinder itself and burn there the result would in time be a deposit of carbon on the piston head or some other part of the combustion space. This carbon would in time start to glow and thus cause pre-ignition, and hence a pound in the motor.

A set-bolt placed in the bottom of the trap plays the rôle of a drain and in case of its becoming filled it can be emptied by means of this arrangement. To elaborate on this idea it is only necessary to hot-water-jacket the reservoir and thereby enrich the mixture with the gas generated by the heated nonane or pentane, as the case may be.

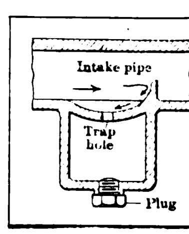

Fig. 6—Common form of gasoline trap inserted in intake line

Removing Piston Rings From Pistons.—In removing piston rings, lay down on the surface of the piston three or four strips of very thin flat steel. Raise the first ring out of its groove, either by expanding it by means of special tongs or by simply picking it up as best you can. Then slide the flat strips of steel under this and slide the ring along on the strips until the top is reached, when it may be picked off. The reason for the strips of steel is, first, to allow the rings to slide easily, having a uniform surface to slide on, and, second, to prevent the second and later rings from drooping into the open grooves made by the first ring. It is not always convenient to take the bottom ring off first, and even if it were done there would be the other rings to pass over, which is just as difficult as passing over an open ring space. Care should be taken not to scratch the delicate surface of the piston rings with the hard pieces of metal.

Oil Leads Often Clog.—In the force-feed system of oiling there is generally far more oil supplied to the motor than is absolutely necessary. The usual methods of force-feed oiling do not depend altogether on the force-feed system to do all the lubricating of the machine, but have an auxiliary splash system. Many very fine systems, however, rely wholly on the force-feed and while there is as a rule a good margin of safety left when the system is designed, a plugged-up oil lead may have very serious consequences if not detected after a time. There are several ways of conducting the oil from the mechanical oiler through the motor, the most common being that of leading the oil to the main bearings and from there through the drilled crankshaft up to the lower connecting rod bearings. The force pump is considerably aided by centrifugal force in sending the oil on its way to the crank bearings, so that when the oil reaches this point it has the necessary momentum to send it up into the wrist pin bearing.

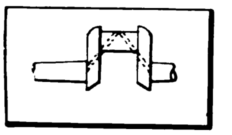

Fig. 7—Slanting oil leads cut in crankcheek and pin, very often used in conjunction with centrifugal ring

Should the hollow crankshaft become stopped up the oil would take a different course than that which it is intended to take, thus leaving the bearings dry. There are two ways of drilling the crankshaft in common usage. The most frequent, shown in Fig. 7, is drilled on a slant directly through the crankpin and crankcheek into the crankshaft. Or, if the leads are not drilled into the crankshaft they are led to an oil ring called a centrifugal oiler, which is a ring resting on the crankshaft. The ring is arranged with a rim so that as the oil is sent to the perimeter by centrifugal force, it is retained there, while the oil which is opposite the hole in the crankcheek is forced through up the slanting grooves into the lower connecting rod bearing. The method of drilling the oil leads through the crankshaft depicted in Fig. 8, is of course, not adapted to the centrifugal ring, but is intended for cases in which the oil is sent through the crankshaft from the main bearing by means of an oil hole and from there is forced up to the various leads until it reaches the wrist pin.

A stoppage of the oil flow within the crankcase itself would not be such a serious matter at medium speeds, as there is always an oil vapor in the crankcase which is generated by the swiftly revolving cranks. Should the new supply be cut off for any length of time though, the results would become very serious if heed were not paid to the warning signs which would be given forth by the heating motor. A sudden loss of power and perhaps pre-ignition causing a knock while turning at low speeds would evince itself if the case were serious enough to cause a shortage of lubricating matter to one of the bearings.

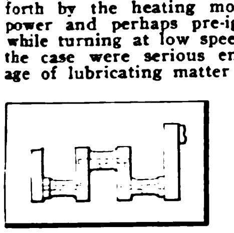

Fig. 8—Oil leads in crankshaft used in force feed system where oil is pumped up as far as wristpin bearings

Should the sight feed indicate that the oil were flowing properly and still these indications of overheat forced themselves into prominence it would often puzzle even an experienced driver, as he would probably put the blame on the water circulating system at first, and if that proved to be all right, would then wonder what the trouble was. When the oil leads are drilled they are of course drilled all the way through the various pieces of metal and are then plugged to the required depth by means of a screw. When the leads become stopped up within the crankshaft or crankcheek these openings prove themselves a real boon, as the screws simply have to be removed and a copper wire run through the hole to remove the residue which has been deposited therein. A warning may be read in the fact that this impediment to the flow of the oil will be found to be a thread of cotton waste much more frequently than an impurity which was present in the oil when bought.

The reason for this oil waste being found so often in the oil circulating system is that when cleaning out the tank or other parts of the machine cotton waste will be employed to wipe off the superfluous matter. This waste will leave threads on the rough walls of a casting, which work loose and collect in some place where they will eventually give a great deal of trouble. When using waste around any part of the machine which comes in contact with moving parts it should be very carefully removed so that accidents of this nature do not occur.

Drainage Troubles Will Crop Up.—The makeshift drainage trap which is often slapped into place by an incompetent or perhaps an amateur plumber, which often amounts to the same thing, is as a rule a rather ineffective piece of mechanism. The greatest mistake is to put a bend in the pipe under a drain and expect it to perform the office of a trap in a satisfactory manner. It might do so for a time but eventually will cause trouble. Smells are bound to arise from a drain if it is not adequately protected from them by some means of sort of baffle, a water-sealed bell by preference. The cuts shown herewith illustrate the correct and incorrect types of trap to use. Fig. 9 illustrates the unsatisfactory type which is often installed in careless work.

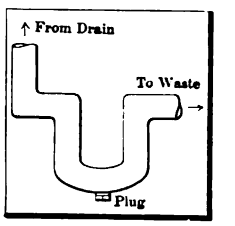

Fig. 9—An amateur's job commonly seen. A very poor form of trap

Fig. 10 shows the bell type. The drainage first flows through a strainer so that no large pieces of solid matter are allowed to flow into the drainage pipe in the first place, so that there is a very small chance for the system to be clogged in this manner. The water is poured in as shown until it covers the edges of the bell baffle, thus effectually sealing the waste pipe so that no smell can pass from the foul pipe up through the strainer into the garage or whatever is being drained by the system. The cup formed by the casing of the trap below the bell can be very readily cleaned out by removing the strainer cover and by means of a wire or small scraping tool the sediment can be taken out. This should be done very often so that the bell trap does not forfeit its own purpose and become a trap for waste matter instead of a device to prevent foul atmosphere in the space which the drainage system takes care of.

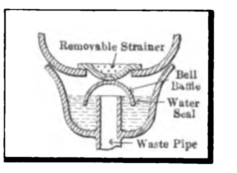

Fig. 10—Bell stench trap used in careful drainage work to keep dangerous odors from the room drained

Action of the Centrifugal Pump.—The action of the centrifugal pump is practically the exact reverse of the action of the ordinary water wheel with which we are nearly all familiar. The efficiency of the water wheel and the conditions under which it acquits itself with the greatest amount of satisfaction are the same as those under which the water turbine is found to be of the greatest use and satisfaction, that is, where there is a positive and continuous flow to be maintained against a back pressure or head which is not excessive.

The power given to the shaft of the centrifugal pump is transferred to the water by means of a series of radial vanes which are illustrated in Fig. 11, showing a section through the pump chamber. The water is led to the center of the revolving group of impeller vanes and is picked up by the slower moving parts at this point without shock or noise. It is then conducted by means of centrifugal force to the outer ends of the vanes. During the flow to this point the water has accumulated a greatly accelerated motion and pressure until it has absorbed all the power which is transmitted to the pump shaft and has not been lost in mechanical ways, as in overcoming friction, etc. The most satisfactory pump will be the one which has given the water the maximum velocity and pressure with the minimum amount of noise, shock and friction.

The water pump on an automobile is generally of the centrifugal type, and for the use it is almost ideal since there is no appreciable head to pump against and the velocity of flow is required to be somewhat high. The water pump is generally driven on a full-time gear ratio, that is, the speed of the pumpshaft is the same as that of the crankshaft. Very often the magneto is driven off the same shaft as the water pump, the shaft in most cases running longitudinally with the motor. There are a few notable exceptions to this, however, the shaft being placed laterally across the front end of the engine.

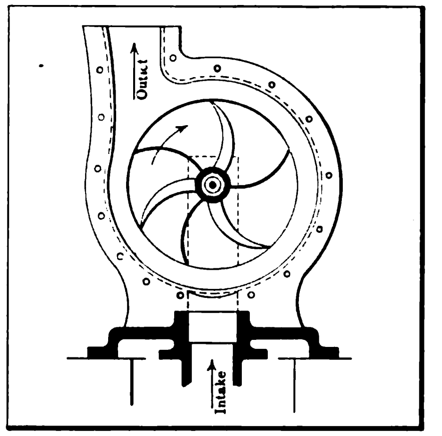

Fig. 11—Common form of centrifugal water pump, much used on automobile water circulating systems

In a case where the pressure required is high it is obtained at the expense of the velocity. The speed of the water is slowed down in an annular diffusion space which is designed so that the contraction is as gradual as it is possible to make it so that there will be no needless waste of energy in making eddies or whirlpools within the casing. With a proper design of the diffusion space and volute it is possible to transform nearly all the energy of velocity into that of pressure so that the pump is capable of working against a normal head without any difficulty if it is well designed. The automobile water pump has not much head to overcome, as a rule, so that the pump can be designed to give a very satisfactory velocity through the water jacketing. This velocity is of great importance, as the effectiveness of the cooling fluid depends to a large degree on the rapidity with which it is renewed.

Since the continuity of flow is of great importance in the automobile water pump it is necessary to furnish a uniform supply of water to all the parts of the inlet or suction opening of the impeller, for unless all the impeller vanes get the same supply of water the continuity will be interrupted.

A Tool of Great Utility.—Clamps are of such universal use that it is not usual to find a garage or any shop where there is any repairing done at all which is not equipped with a number of these instruments. In purchasing clamps great care should be taken that they are adapted for the work to which they are to be put. The accompanying illustrations show two types of these tools. The clamp shown in Fig. 12 is a cheaper tool that that shown in Fig. 13. It is a very good tool, however, and is very satisfactory if it is able to perform the work. For heavier work, though, the more costly clamp will probably be required. In wood working, tire repairing, and like odd jobs, the lighter of the two will be perfectly satisfactory. In tightening the clamp care should be taken that it is not fastened to some delicate surface which will be damaged by the pressure exerted. If there is any risk of this a piece of soft wood may be inserted which will remove the danger to a large extent. One of the great objections to the type of clamps generally on the market is the winged nut, the projections on which are so small that it is not possible to bring it to the required tightness by hand; in this case a wrench will be required to overcome the difficulty.

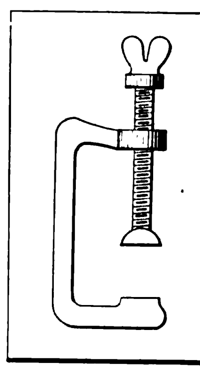

Fig. 12—Type of clamp used in lighter work, such as wood working

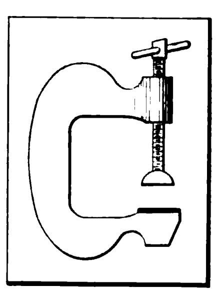

Fig. 13—Heavier clamp employed in metal working or any heavy work where such a tool is required

Carbureters with Sunken Jets

The Tendency in Modern Foreign Practice

This article, which appeared in "La Vie Automobile," discusses the tendency in modern carbureter construction, utilizing several different makes of carbureters as examples in dealing with the principle of the sunken jet. The author endeavors to show what must be done to make a carbureter automatic.

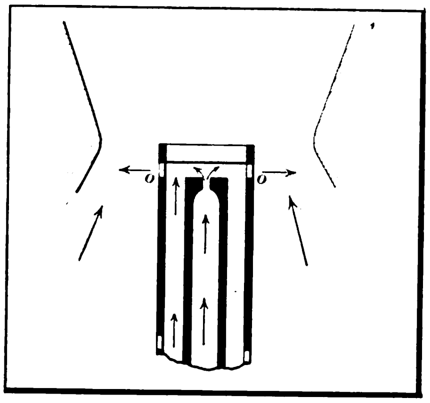

Fig. 1—Section through the Claudel jet showing the air passage way around the jet proper

CARBURETERS with automatic air adjustment seem to be on the decline, according to the author, which no doubt applies to the types manufactured in Europe. The majority of carbureter "specialists" have dropped that idea. The vogue now is for carbureters with a fixed air intake without any adjustment for the air or gasoline and without adjustment for the automatic air intake. The modern method is the regulation of the gasoline automatically.

It is conceded that all methods that assure automatic operation will give the same results; nevertheless the automatic regulation of the gasoline seems to prevail owing to its simplicity and the fact that it eliminates all moving parts.

A mechanism, no matter how delicate it may be, can run for a long time without getting out of order if made with care and fitted methodically. Unfortunately every driver loves to tinker with his carbureter, and more than ever when his ideas of carburetion in general are a negligible quantity. The motor may knock a little; immediately, not enough gas! and he proceeds to close the valve or stop up the additional air ports. With what result? The motor knocks just the same and instead of using 15 gallons it uses 25 gallons. If the motor heats because the fan belt slips or because the ignition has not enough advance, or any other reason for a matter of that, the carbureter is blamed. Too much gas! The jet is given a blow to close the hole and the air holes are enlarged. Result: The motor no longer responds and loses its vivacity. It is a difficult matter to make some drivers understand that for the most part it is a physical impossibility for the carbureter to cause the motor to knock or overheat or at any rate that the influence of the carburetion on these two phenomena is extremely small and should not find a prominent place in daily practice.

As it is difficult to inculcate these ideas into drivers' heads, it remains to give them carbureters that they cannot put out of order owing to the absence of adjustments. Then the only reason for the jet to be taken apart should be initial adjustments or cleaning. Even then if a fine wire gauze filter is interposed in the gasoline circuit it should never be necessary to remove the jet, and if this part were fitted with a difficult means of taking same apart the driver would have little desire to tinker, thus avoiding troubles that might arise from his lack of knowledge.

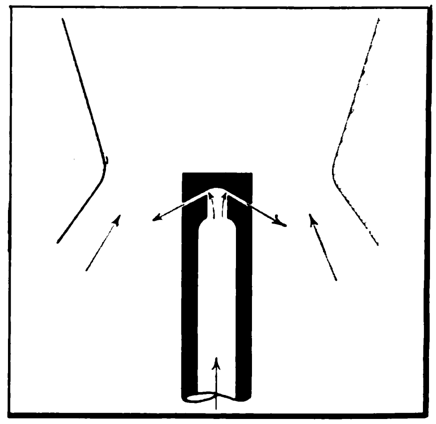

Fig. 2—Section through another type of jet in which the outlet is deflected downwards

Automatic Methods of Regulating the Gasoline

It has for many years been thought impossible to realize an automatic system of controlling the gasoline flow without utilizing any moving part that is affected by the depression caused by the motor. The problem is shortly this: A way has to be found of preventing the gasoline from surging from the jet in too great quantities when the speed of the motor is increased, or, to be more exact, when the depressions on the jet are increased.

Several systems have been proposed in the last few years which can be divided into two classes: placing a braking effect on the gasoline, and the flooded jet.

The Claudel is the prototype of the first system in which an ordinary jet is surrounded by a funnel or air circle. The air and the gasoline leave the upper part at the same time through small holes drilled laterally. It will be understood that at

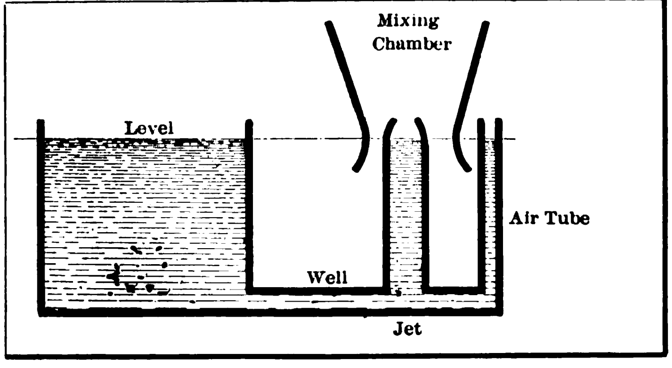

Fig. 3—Section through vapor carbureter, showing the method of sinking the jet under the level of gasoline

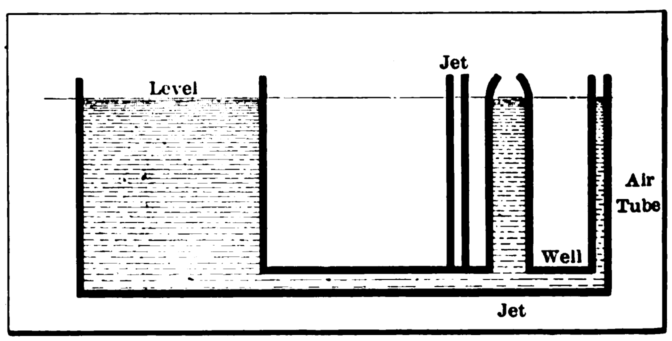

Fig. 4—Section through the Claudel carbureter, showing the well containing the jet and the compensating jet alongside

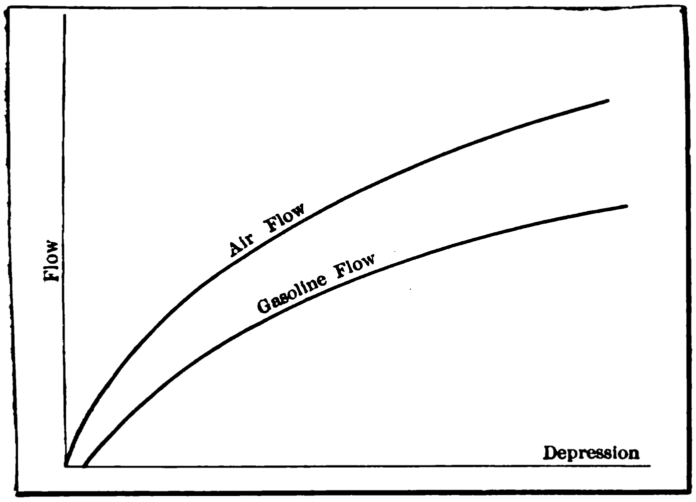

Fig. 5—Diagram representing the differences between the flow of air and gasoline in an ordinary carbureter

high speeds of the motor the air which is forcibly aspirated in the funnel will abut at the end of this chamber, and set up a counter-pressure at the orifice of the jet. It follows that the air chokes the passage of the gasoline and prevents an excess of gasoline at high speeds. On the other hand an energetic mixing is produced in consequence and the gasoline leaves the orifices O in Fig. 1, divided in minute particles, which facilitates its subsequent vaporization.

An analogous system but of simpler construction is shown in Fig. 2, which consists of directing the orifices of the jets so that they are opposed to the direction of the incoming air current. The angle of inclination must be determined by practical tests. At high speeds the air current tends to draw the

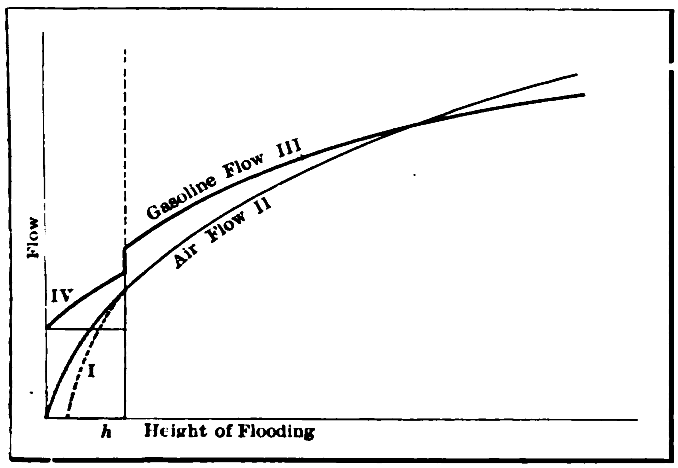

Fig. 6—Curves taken from tests of the Vapor carbureter, the dotted line I indicating the flow of gasoline up to the time the well floods

gasoline from the jet and to push it back at the same time.

The question arises then as to the point where compensation exists, leaving the mixture more or less constant, and this is more difficult to estimate. It is possible to arrive at practical results with the Claudel carbureter, which is in itself an example or proof. But an absolute automatic action is not attained by this method, as may be seen from the slow picking-up qualities and the loss of power on hills. In spite of its simplicity this system has been abandoned by its most staunch adherent, Claudel, who has gone over to the flooded jet.

Flooded Jets

As the name implies, this is a jet placed below the level and through which the gasoline tends to flow constantly on account of the difference in levels. In order to eliminate a mechanical means of closing the jet when the motor is not running it is placed at the bottom of a well, as shown in Fig. 3, the sides of which are slightly higher than the level of the gasoline. When the motor is at rest the well fills up to the level of the gasoline, completely drowning the jet and preventing it from giving off any more gasoline. An air passageway in communication at one end with the base of the well and at the other extremity with the exterior allows air to pass in and carry with it the gasoline given off by the jet.

When the motor is stationary the well and the passageway, as has been shown, are filled up to the corresponding height of the level in the float chamber. As soon as the motor is started a depression is produced in the mixing chamber or throat. The gasoline tends to rise in the well to a height equivalent to this depression. But, as the sides of the well are scarcely any higher than the level, the gasoline leaks or dribbles along the walls of the well and is carried along, at any rate in part, by the lapping effect. At this moment the carburetion is very insufficient because the gasoline that trickles along the outside walls of the

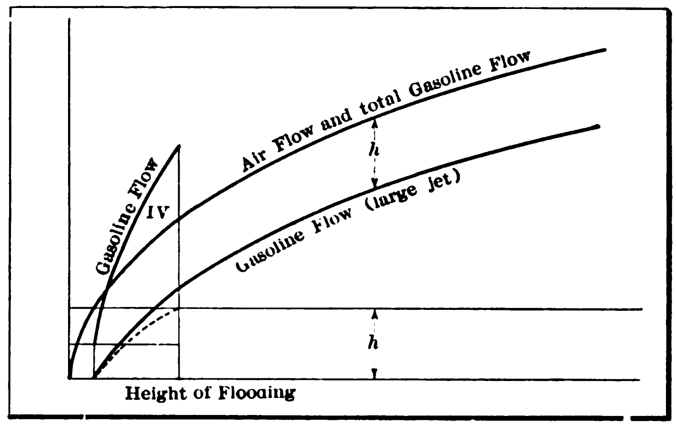

Fig. 7—Curves taken from tests made with a Zenith carbureter

well is not vigorously vaporized and carried in by the current of air. The flow of gasoline is then that of an ordinary jet acted upon by the depression which obtains at the orifice of the well. According to the degree that this depression increases the level decreases in the air passageway and as soon as the depression is equal to the column of gasoline which is flooding the jet, the air will enter the passageway, carrying with it the gasoline that remains in the well, and leave the extremity of the latter, passing into the mixing chamber.

At that moment there is a discontinuance of the procedure, as the depression which exists in the mixing chamber makes itself felt in the base of the well as soon as it is empty. And the moment the gasoline is taken from the well the depression, which was as great as the height of the flooding, suddenly becomes double. Further the flooded jet does not come into operation until the depression is sufficient to expel the gasoline

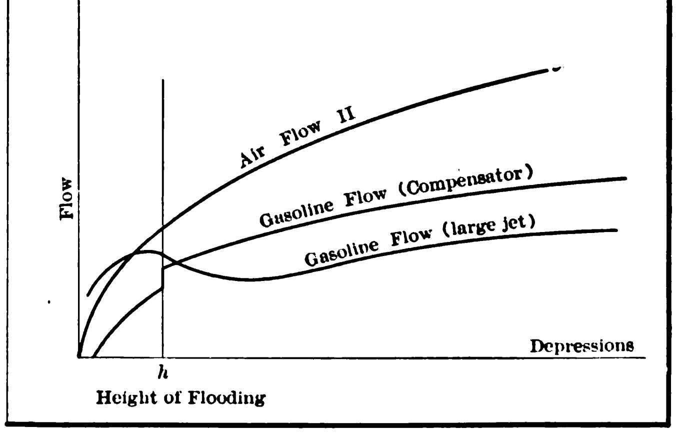

Fig. 8—Showing the flow from the large and compensating jets of the Claudel carbureter, together with the air flow

from the well; but at that moment it is stirred up, leaving the orifice of the well, and then intermingles with the air. The gasoline thus expelled, which operation is not the least of the advantages of the flooded jet, makes an effective combination, producing a good mixture even with small depressions, which is equivalent to slow-speed running for picking up and running on a grade.

With the engine running slow and the car standing still it is necessary to resort to an artifice. In the Vapor carbureter a small lead not shown in the illustration, Fig. 3, takes the gasoline at the mid position of the well and atomizes it on the flap of the butterfly valve. Until the well has been thoroughly primed, and it is always half so, the jet sprays into the mixing chamber. Fig. 6 shows the relation of the curves of the gasoline flow, which more nearly approaches the air flow than is obtained in ordinary carbureters, the relative curves of which are shown in Fig. 5. It is impossible to arrive at perfect compensation with this type of sunken jet, but on the whole a good result is obtained.

As a matter of fact the delivery of the gasoline is caused to leave the axis of the abscissæ from another point; in other words, it is displaced horizontally instead of vertically, which is necessary to assure a perfectly theoretical compensation. Too much importance must not be attached to these reasonings, which are rather in the nature of indications than scientific truths.

Another type of flooded jet obtains in the Zenith carbureter, which was probably the first of this kind. In this carbureter the sunken or flooded jet, which is not submitted to the depression and consequently has a constant flow, is in communication with an ordinary jet and the combination of the two permits a theoretical automatic operation which is at the same time practical. At very slow speeds and when the well is not primed the gasoline leaks not only out of the large jet but also out of the cap. The large jet and the compensator therefore deliver both at the same time. Unfortunately, however, the gasoline that flows does not become entirely utilized in the suction unless a hot air intake arrangement is provided. In order to have the gasoline thoroughly atomized it is precipitated on to the flap of the butterfly valve and as it is given off by a sunken jet it is delivered in constant and equal quantities independent of the depression. The horizontal line in Fig. 7 denotes this. The total gasoline flow is represented by the curve IV. This curve is purely theoretical, as all the gasoline is not carried along. From the moment that the well is filled the air and gas curves become confounded.

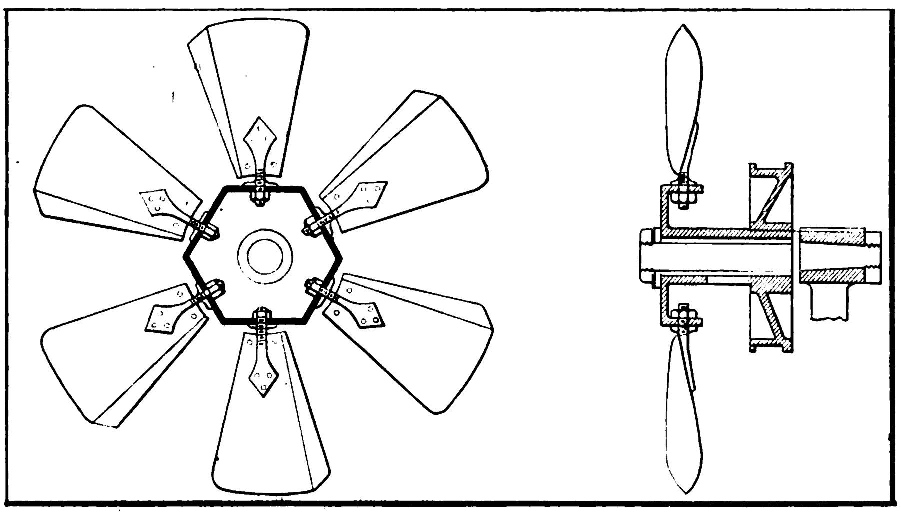
The new Claudel carbureter is very similar to the preceding ones, but it is very difficult to theoretically explain its workings. As a matter of fact a sunken jet under the influence of the depression and identical to the Vapor shown in Fig. 3 is joined with another jet similar to the older type as shown in Fig. 1, which means in other words that the old Claudel jet is combined with a sunken jet.

It is clear that this disposition is not entirely automatic in operation. In fact, a given depression above the choke throat or a given flow of air and a given flow from the sunken jet do not correspond to a fixed flow from the large jet. This flow is variable according to the aperture of the choke. It is not possible to represent the flow of this jet according to the workings of depressions in the mixing chamber before arriving at the throat. Therefore a curve is given which will approximately correspond to the working of a motor giving off full torque. In practice this lack of automatic operation is perhaps very small; in fact, it may be a negligible quantity under certain conditions. The duty of the large jet is above all of importance at slow speeds; that is to say, when the flooded jet is hardly operating at all. The weak point in the old Claudel is thus eliminated—viz., slow picking-up qualities—by the addition of the sunken jet. A careful adjustment permits one to arrive at good carburetion for all points of the sector and all practical speeds. This incomplete article shows the new field that has been opened up of late years in carburetion.

A Suggestion in Fan Design

It is no uncommon sight in the Winter months to see radiators on cars partially covered with strips of metal or leather to prevent the water from getting too cold.

THE radiator has to perform the duty of dispersing some of the heat contained by the water after it has fulfilled its task of maintaining the cylinders at a uniform temperature. It stands to reason that the maximum efficiency which will obtain at a given temperature will diminish if the temperature of the water is raised or lowered materially. This phenomenon is exemplified when the fan belt breaks or slips, in which case, if the outside temperature of the atmosphere is high, the water will in all probability boil. Therefore, if the fan is so made that the pitch of the blades can be altered so as to cause a greater or lesser suction, it should be possible to maintain the circulation water at a uniform temperature all the year around. One method of accomplishing this can be seen in the accompanying illustration. The fan bracket carrying the blades and pulley wheel may be cast from aluminum in the manner shown at B. The blades proper are made from sheet aluminum, the sides of which are given a slight bend in the manner indicated. It is possible then to attach the blades to suitable feet which pass through a hexagonal boss, being held in position by spring washers and nuts. The amount of pitch given to the blades will determine the suction through the radiator.



Type of fan, which permits alteration of pitch to maintain the water at an even temperature despite the variations of atmospheric conditions

There would be no difficulty in reversing the pitch of the blades in Wintertime and forcing hot air upon rear side of the radiator, thereby warming it to counteract the low outside temperature. The pitch could be altered without dismantling the fan in any way, as the nuts holding the blades in position are accessible from the rear of the bracket.

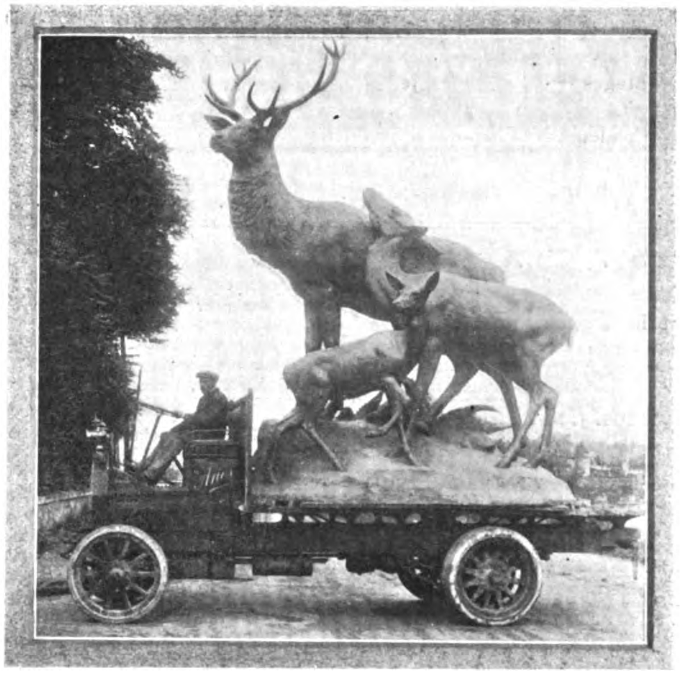
The design of a fan in the first place is largely a matter of trial and error, based on experiments until a compromise is obtained which most nearly conforms to the given conditions. Another advantage possessed by this fan is that three other blades may be removed without interfering with the balance in any way. From some tests on this type of fan it was found that by altering the pitch slightly and removing three of the fan blades the circulating water would retain practically the same temperature in Winter as in Summer.

It may seem difficult to some to determine whether an alteration in the pitch of the blades has increased the suction of air or has caused it to decrease. A thermometer test will show the difference in temperature, but a rough and ready test can be carried out by placing a handkerchief or piece of paper on the face of the radiator, and the ease with which the article can be removed when the motor is running will act as a guide, providing the fan belt has the requisite amount of tension to eliminate slip.

It is of vital importance that the hood should have a good seat upon the ledge of the radiator if the fan is to perform satisfactorily. The practice of fitting a strip of rawhide on the ledge to prevent rattling sometimes leaves spaces for the air to find an inlet which should pass through the interstices of the automobile radiator.

A Novel Motor Wagon Load

The accompanying illustration depicts the bronze statue which has recently been cast in Paris, and which is intended to be erected in the town of Nantes. The statue is no less than 17 feet high, and weighs about 3 1-2 tons. Seeing that it could not be conveyed to its destination either by rail or river, the problem of its transport presented some difficulty. However, after some negotiations, the Aries Automobile Company of Villeuve-la-Garenne, Paris, undertook the work with one of their motor wagons, which, with only a single person in charge, successfully conveyed the statue to the town of Nantes in three and one-half days and entirely without accident. The feat is being duly appreciated in freight automobile circles on account of the difficulties involved.



How a huge statue was transported from Paris to Nantes

TIRE DAMAGE BY CAR TRACKS—One of the great causes of rapid tire wear is the penchant of some chauffeurs to run their machines on the tracks of trolley car lines. Tracks of any description should be avoided as much as possible by careful drivers.

INTELLIGENCE is chained to a stump, as it were, by the man who permits his skepticism to blind his foresight. As an illustration of the devious ways that skeptics arrive at conclusions the following letter will suffice for the purpose: "You continually favor the makers and blame the users of tires. You follow the lead of the tire manufacturers, who advocate a degree of inflation that few cars can stand. I point out also that even the passengers would object to the hardness of the tires that comes from this degree of inflation. In the meantime if the degree of inflation advised by the makers is necessary, why don't you put it up to them to provide tubes that will hold this pressure? I have tires 34 x 4 and am provided with at least 20 tubes that are described as the best makes, but not one of them will sustain under a pressure of 75 pounds per square inch. I find that starting with a pressure as above it is scarcely more than four days before the pressure reduces down as low as 35 pounds. Moreover, I am sure that this pressure does not leak out through the valves. I am informed by one who has every opportunity to know that tires can be made of the type that will scarcely have to be inflated up to the hardness as advocated by you, and my informant also states that a greater mileage may also be expected if the tires are not inflated to such great hardness as you are in the habit of indicating. I believe that you should take this matter up in the interest of users of cars, remembering that the manufacturers of tires advocate a degree of inflation that the tires will not hold, a degree in fact that few people will use, and from all appearances tire makers skulk behind this inflation situation.

(Signed) "H. W. W."

* * *

UGLY as the inference is coming from this reader of THE AUTOMOBILE, it affords an opportunity to point out that the logic of the criticism is defective since, in all fairness, the reader merely accepts the opinion of an individual who claims to have inside information rather than the expressions relative to tire inflation problems as they have appeared in THE AUTOMOBILE from time to time. If our worthy critic will take a piece of wire and bend it back and forth a few times he will doubtless succeed in breaking the wire. If this method of flexing a piece of wire will result in its destruction in a brief space it only remains to observe that flexure in a tire will accomplish the same destruction, but the reason why cotton fabric is employed rather than the wire as above referred to is because cotton is better able to survive the wiles of flexure; but even this excellent material breaks down in time, the measure of which depends upon the quality of the cotton, its weave and amount of flexure.

* * *

WHEN an automobilist finds that properly inflated tires produce disagreeable vibrations, especially when a car is traveling at a high rate of speed, it is optional with him to reduce the degree of inflation of the tires in order to promote more agreeable conditions of riding, but the life of the tires will be enormously decreased on account of the ills of flexure, whereas the real remedy lies in properly inflating the tires and for the rest it is a mere matter of regulating the speed of the automobile so that disagreeable vibrations may be avoided. There is room for improvement in the making of tires, and those who have the best interest of the automobile art before them are quite as keen in their advocacy of the production of good tires as there is any occasion for.

* * *

LEGISLATION as it relates to the use of the highways by automobilists seems to be of the type that accords with the condition of the automobile art of a decade ago, and it suggests the thought that legislators have failed utterly to keep pace with the growth of this newer industry, which has reached substantially the third place in the leading industries of America, thus bringing into bold relief the glaring inconsistencies of the men whom the States intrust with the framing of the laws relative to the highways and their proper use. The impression is gaining force that some of the legislative methods in vogue are founded upon a type of stupidity that will lead to disaster. Take the State of New Jersey as an illustration. Its citizens freely admit that automobilists generally are among the most intelligent of the nation's makeup. But in the face of this fact the legislative forces in the State of New Jersey have built a wall around that State depriving these intelligent citizens of the right to traverse its highways excepting under conditions that would affront the intelligence of a skate. It is a mere matter of time, of course, when the citizens of New Jersey will awaken to the fact that they are being put to great loss, but it will take a number of years for the State to regain what it is losing through its failure to encourage the principles of reciprocity.

M. C. A. Clears Sporting Skies

Bans Half-Mile Tracks and Sifts Rules

Half-mile dirt track racing was killed; mile track owners were ordered to take precautionary measures to insure safety and supervision of such racing was provided; weight restrictions in stock car race was limited; weight restrictions in stock car classes were raised and truck contest sanctions were restricted to regularly organized automobile clubs by the recommendations of the M. C. A. in its meeting at Detroit last week. Many more legislative changes were considered and discussed.

DETROIT, Aug. 14—A number of radical changes in the rules governing automobile racing were discussed and recommended to the Manufacturers' Contest Association by the executive committee of that body which met here Thursday and Friday. The most prominent of the recommendations are as follows:

Refusal of all sanctions for racing on half-mile dirt tracks.

Mile-track associations to be given sanctions only after safety has been approved by a member of the Contest Board.

The number of starters in any race to be limited to one for every 400 feet of track.

The elimination of the weight restriction in stock car races and the limiting of such events to such cities only as offer a market which may be influenced by the results of the events.

Refusal of truck contest sanctions to any but regularly organized automobile clubs.

In addition a committee was appointed to wait upon the N. A. A. M. at its next meeting, for the purpose of securing from that body financial backing which will enable a more thorough supervision of the sport. Ways and means to this end were discussed though not formally voted upon. Some of the members of the committee were in favor of placing the Contest Board in the position of race promoter while others believed that close supervision of the work of the promoters and the presence of an authorized representative of the Board would be sufficient.

President Howard Marmon of Indianapolis presided over the sessions of the committee which were attended by 15 members, as well as Chairman Butler of the A. A. A. Contest Board, David Beecroft and F. E. Edwards of the technical committee of that body, and George Robertson, president of the Racing Drivers' Association.

It was the unanimous sentiment of the committee that racing on dirt half-mile tracks should be abolished. The committee would also have made a similar recommendation regarding the mile tracks, but for the fact that this would deprive many cities of the sport altogether. Its recommendation in this respect is for a rigid examination of all such tracks before sanctions are granted. Specific recommendations are that the tracks shall be oiled several days before the meeting and that the inner rails shall be lowered to such an extent as not to interfere with the safety of the drivers whose cars shall happen to be diverted to the infield of the course. This was done on the advice of George Robertson, who advanced the theory that a large share of injuries from such accidents were the results of the height of the top boards of such fences. To further insure the carrying out of such safeguards it was recommended that every promotor give bond for $500 that precautions will be taken.

The elimination of the weight restrictions on stock car races was a general surprise, the significance of which is not readily apparent. It was rumored, however, that several companies which were very anxious to have this done, stood ready to not only take an active share in racing but also to lend financial assistance to the Contest Board in its endeavor to secure a firm footing and to guarantee the presence of at least one of its members at every race meeting.

The recommendation regarding the elimination of sanctions to corporations and individuals other than automobile clubs was made to prevent the securing of gratis advertising by such promoters. While truck and delivery wagon contests were particularly mentioned in this connection, the recommendation applies to all sorts of competitions between motor cars.

All the recommendations will be presented to the parent association at its meeting in New York, September 6.

The first topic to be taken up was that of the proposed Glidden tour for October which is scheduled to run from New York to Jacksonville, Fla., by way of Atlanta, Ga. This tour is scheduled to be a good roads booster scheme and as such, Chairman S. M. Butler, of the Contest Board, asked that the entering of cars by private owners be simplified by not requiring said cars to be registered. At present it is necessary that stock cars be registered with the contest board before they can compete in any reliability run. There are a few manufacturers who have refused to register their cars this year. They have refused to register them in order keep their dealers and owners from entering contests. Chairman Butler explained that there are many owners of these unregistered cars who wish to enter this southern Glidden, and it was for the benefit of these that the demand to eliminate the stock registration clause was introduced. After continuous discussion it was decided to make no change in the rules so that only registered stock cars will be allowed to compete. Representatives of some makers present frankly admitted that they did not want owners to enter contests and had refrained from having their cars registered in order to prohibit owners entering such.

It was the general consensus of opinion that no change should be made in the present stock car rules. It was a matter of general regret that stock car competition has not been entered into with greater vim by the manufacturers this year. The Elgin races will be practically the only large stock car events of the season. It was resolved that for the 1912 season a contest committee be asked to sanction twelve stock car events in which its technical committee will attend. These events are to be scattered through the greatest market sections of the country.

It was the unanimous opinion of the many delegates that additional precautions be taken in the matter of roadway, beach and track races. It was accordingly recognized that in all speed contests a mechanic must ride with the driver. This also applies to practice for road races or track meets.

Among those representatives attending the meeting were: Howard Coffin, Hudson Motor Car Co.; Howard Marmon, Nordyke & Marmon Co.; S. M. Butler, Chairman Contest Board A. A. A.; F. E. Edwards, Chairman Technical Committee A. A. A.; C. E. Emise, Lozier Motor Car Co.; M. C. Meigs, J. I. Case Threshing Machine Co.; N. A. Hawkins, Ford Motor Car Co.; J. H. Newmark, Oakland Motor Car Co.; Mortimer Reeves, United States Motors Co.; A. W. Markham, Mais Motor Truck Co.; E. W. Curtis, Electric Vehicle Association of America; Elmer Pratt, Pierce-Arrow Motor Car Co.; George H. Robertson, President Racing Drivers' Association, and Russell Field, secretary, Manufacturers' Contest Association.

Success Crowns Dead Horse Climb

Biggest Eastern Event of Season Is Held

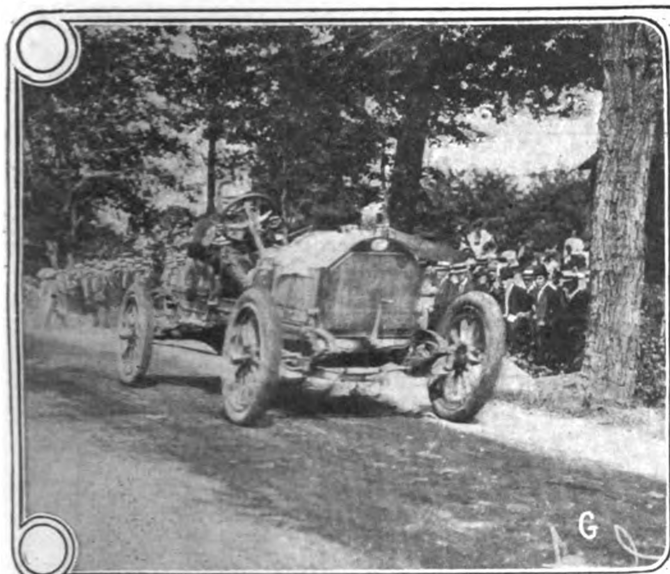
Thirty-four cars, representing the stock models of sixteen makes of American automobiles contested for hill-climbing honors at the sixth annual renewal of the Dead Horse Hill Climb under the auspices of the Worcester Automobile Club, Saturday. The cars representing the National, Cole, and Oakland factories won every event in which they were entered and a special National won four races, and in addition thrice lowered the record of the hill for gasoline cars. There were eighteen races decided.

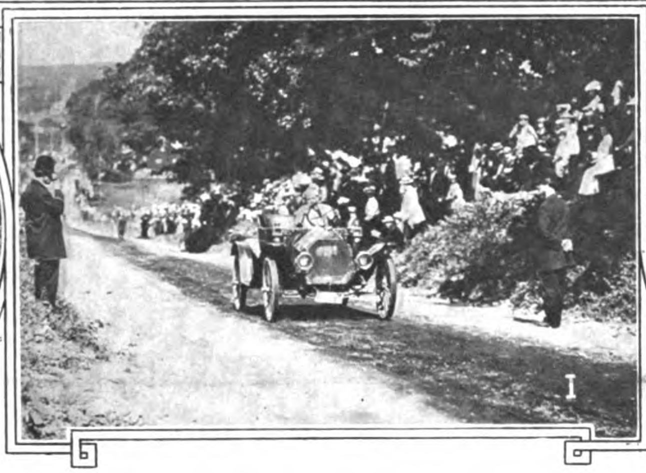
WORCESTER, MASS., August 14—Dead Horse Hill was mounted sixty-one times during the sixth annual hill-climbing contest under the auspices of the Worcester Automobile Club on Saturday afternoon.

Records were lowered all around and a new mark for gasoline cars on the course was set. The three-year-old record of the hill, made by a Stanley steam car (Baldwin) at 54 seconds flat was not quite reached. A four-cylinder National with the regular stock diameter of cylinder but with a stroke elongated to 7 1-2 inches and rated at 50-horsepower swept the boards in the free-for-all classes. Four times this car started with a factory driver at the wheel and four times the officials announced that it had won. Each of these events developed the hottest sort of a contest, for the big brown Knox car that made such a creditable showing at Indianapolis on the occasion of the late 500-mile international sweepstakes, pushed out the blue car to its speed limit and in the final event for the hill record, came within a second of defeating the National.

The Stanleys which were entered in the big car events did not equal the work of the former season when they made the speed record.

The contest was far and away the most important in a sporting sense that has been held in the East this season so far, and far exceeded any of the former climbs that have been held on Dead Horse Hill.





G—Cole. Jenkins, driver, which won two races in fast time in stock and non-stock classes

F—Showing how the spectators massed on the natural grandstand formed by the side of the hill

J—Buick, No. 13, which won the 161-230 cubic inch class race

I—Krit, No. 24, Pilling, driver, winner of the 1A race—$800-and-under class

H—The Gramm five-ton truck negotiated the hill with a full load

There were thirty-two starters in the various events not reckoning ten motorcycles which competed for two prizes. One of these, an Indian number 34, ridden by Frank Hart, lowered the record of the hill for this type of vehicle by making the climb in 54.60 seconds.

There was a tremendous crowd out to see the races and the club handled it in such a way that it probably made a handsome profit out of the affair. The lower end of the course was boarded in and admission to the side hills was charged. Of course everybody who saw the contests did not pay, but a fine percentage of them had to. Then, too, the prizes in the various classes consisted largely of certificates issued by the club showing the performance of the cars.

A more perfect day for the climb could hardly have been made to order. It was warm when the sun shone but the sky was partly overcast and the temperature delightful. The course was not smooth and despite its preparation for the climb was dusty. The running of the numerous trials was done accurately and promptly and the whole affair reflects much credit upon the club.

Sure enough stock cars competed in their various classes and gave a comparative exhibition of their prowess and powers in competition with similar cars which is expected to do much toward stimulating business. Every entry in Classes A and B which include respectively, equipped automobiles according to price classification, and stripped stock chassis, were examined and checked over by A. F. Camacho as technical representative of the Contest Board. On Friday night Mr. Camacho was informed that there might be a protest lodged against the Cole pair entered in their stock chassis class and he pulled down the cars, measuring the cylinders and other questioned parts. No difference was discovered between the cars entered and the certified stock models and they were allowed to start. There was also some question raised as to the eligibility of two of the Buicks entered, but it was shown that neither of the cars was a model of the current year and the protest was squelched in its incipiency. All the other cars in Classes A and B were not questioned, but checked up with the certificates.

The timing was done with an electrical instrument, the property of the Worcester Polytechnic Institute and was supervised by Professor David L. Gallup and a corps of assistants from the college. The instrument wrote the record of each climb in an unmistakable way and while the seconds were only divided into twentieths in the announced figures, the hundredths or even more minute decimal fractions could be determined by using a magnifying glass on the tape, if such a course proved necessary in order to differentiate a winner in case of a very close finish. This occasion did not arise during the afternoon.

The first number on the program was for stock cars selling for $800 and less and the only entry to qualify was a Krit. The next larger class was won by an Oakland runabout which defeated a Cameron. The class selling from $1,201 to $1,600 was captured by a bigger Oakland from a New Parry. In the 4A event for cars selling as high as $2,000, Velie number 9 won handily from a Buick (38) and another Velie, while 5A went to a National (40) entered by the Poertner company of New

York and driven by Rutherford. Another National stock car and a Knox (4) finished close up.

In the stripped chassis classes, the smallest class open to cars of less than 160 cubic inches piston displacement was won by a Flanders 20 in the astonishingly fast time of 1:18.85. An Empire was second. Hudson 16, a 20-horsepower car had a walkover in the 161-230 cubic inches class and the 231-300 class race was won by Cole 22 in 1:17.55, with Firestone-Columbus second and another Cole in third place.

Class 4B for cars of 301-450 cubic inches developed one of the prettiest struggles of the day and attracted a field of eight fast cars. The winner turned up in National 1 (Wilcox) who mounted the three hills in 1:00.35, lowering the record for this class. The same may also be said for the foregoing performances of the Flanders in 1B and the Cole in 3B. National 5 was a fair second and National 3 a close third. Another National, a Velie, Knox and two Buicks also ran.

Class 5B for cars from 451 to 600 cubic inches piston displacement was won by Knox 6 (Coffey) in 1:03.60.

In the non-stock sections in which most of the competing cars were in reality stock cars, the showing was also excellent. In Class 2C which corresponds with 2B except for weight restriction, Buick (10) had a walkover.

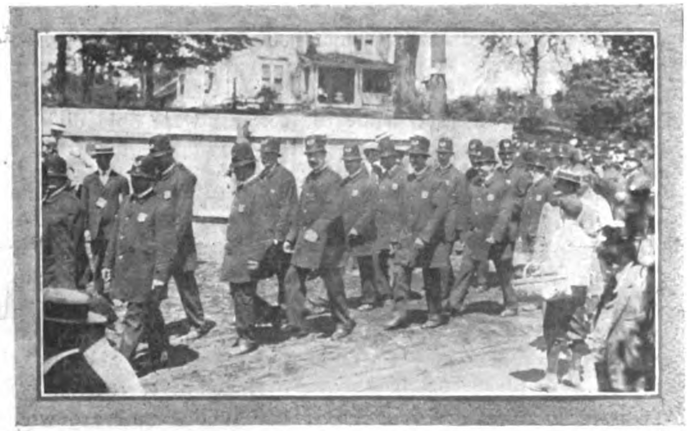
In Class 3C for cars of 231-300 inches displacement, the Cole pair finished first and second, the winner, number 22 turning the trick in 1:16.75. The third place was taken by the Cameron Six.

Class 4C brought out a field of six including three Nationals, a Knox and two Buicks. The finish was in that order, the winner, number 1 National (Wilcox), making the run in 1:01.70.

The 5C class for big cars saw the hill-record for gasoline cars lowered a peg and later in the afternoon it was twice brought down from the new level. National 2, a 50-horse-power machine and said to be a duplicate of the cars that raced at Indianapolis on Decoration Day and of the car that cleaned the boards at the Galveston beach meeting this month, won first honors in 55.70 seconds, over two seconds faster than was made by a Fiat (90) (Bragg), last year over the same course. At that, the car did not get a really good start and did not make the first quarter of the hill at top speed. The Indianapolis Knox almost equalled the time of the Fiat and was credited with 58.80 seconds. Another Knox was third.

Then came the free-for-all events. The first of these was for any kind of an automobile and National 2 (Wilcox) made the ascent in 0:55.50, again lowering the record of the hill. The big Knox was second, two seconds slower and a Stanley Steamer was third, nine seconds after the Knox.

The second race in this class was for the Amateur Championship of Worcester County. The trophy for this race had already been won twice by a Stanley steamer guided by Jay Clark, Jr., and Mr. Clark foreclosed his option on the cup by driving his car leisurely up the hill in 1:15.75 for a walkover victory.



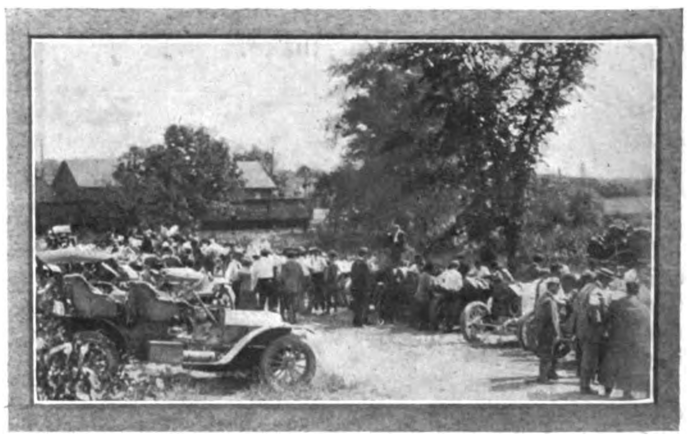
K—Worcester's bluecoats marching up the hill to their stations

The third race was for D class gasoline cars and National 2 again triumphed over the Knox pair.

The final event which was open to anything in the automobile line, for the record of the hill, witnessed another slash at the new mark when National 2 clipped 1-20 of a second from its recently established mark and set the new target for aspiring hill climbers at 55.45 seconds. The big Knox was within a second of the winner's time.

The hill record would have been materially lowered in this event except for an unfortunate occurrence near the finishing line. Wilcox at the wheel of the big car got away to a magnificent start, taking the little bridge just beyond the trip wire with his throttle wide open. Up the first grade, a stiff climb averaging rather more than 8 degrees and infinitely stiffer than the figures apparently show, the car plunged, making a new mark for the quarter distance. Along the little flat bench of perhaps 100 feet the car shot with dazzling speed and entered the 12 degree hill on high gear with the driver's foot hard on the accelerator. The fierce energy of the motor raised clouds of dust under the traction wheels and like a bird the big car mounted the grade that numbers its slain horses by the hundreds. At the top there is another little bench and then a sharp, long grade, the heaviest spot in which is over 20 degrees. Across this flat and charging at the foot of the hill the car began its upward flight to the wire at a terrific rate of speed.

Everybody at the crest of the hill and around the timing apparatus station was tensely awaiting the flash of the monster automobile when a touring car slipping out of its parking space just at the brow of the hill came dashing along toward the wire. The car reached the wire just as Wilcox began to mount the third hill and tripped the machine as the National's exhaust gave warning of its approach under full power. An assistant of Professor Gallup seized the wire and slipped it over its hook again a fraction of a second before the front wheels of the racer struck the



L—General view at the foot of Dead Horse Hill, where the contestants lined up

wire. The National probably lost two full seconds between the crest of the hill and the wire on account of its proximity to the touring car as Wilcox took his foot from the accelerator and even closed his throttle in order to avoid a rear-end collision with the intruder. He did not apply his brakes and by some quick-witted driving missed a bad mess with the other automobile. Except for this happening there was nothing disagreeable about the afternoon's sport, but the car was surely robbed of the honor of establishing a mark lower than that of the Stanley Steamer.

Knox No. 7, the big car driven by Belcher also lowered the last year mark of the Fiat, in this event turning the course in 56.30 seconds. This is 85-100 of a second slower than the winner, but 1.70 seconds faster than the Fiat's time.

The policing arrangements for the event were not of the highest class, as the number of men detailed proved insufficient to handle the crowd, and along toward the end of the card when the big cars were contesting the course was not clear at all times.

One thing that aggravated this condition was the injection of the truck exhibitions between the races. First a Cameron delivery car went up in 2:00.05 and then a fully loaded Gramm truck of five tons capacity made the climb. This car covered the course in 6:25.25 and when it passed many of the spectators thought the last race was finished and swarmed out upon the course. As the big cars were slated to try for the record of the hill after the trucks had passed, the situation was acute for a few minutes. Fortunately there was no accident except that which deprived the National of the absolute record for all classes of automobiles. The summary:

1-A—Stock Cars for $800 and Under

No.	Car.	Driver.	Time
24	Krit	Pilling	2:10

2-A—Stock Cars Selling at $801 to $1,200

15	Oakland	Bauer	1:50.15
21	Cameron	White	3:57.55

View from the grandstand at the automobile beach carnival at Long Branch

3-A—Stock Cars Selling at $1,201 to $1,600

14	Oakland	Bauer	1:37.10
26	New Parry	Wiggin	1:47.85

4-A—Stock Cars Selling at $1,601 to $2,000

9	Velie	Wiggins	1:21.15
12	Buick	Jessup	1:36.60
10	Velie	Wallace	1:48.95

Long Branch Parades

Decorated automobiles paraded Saturday at Long Branch as the culminating feature of the midsummer carnival conducted annually at that resort. Automobiles were used to a much greater extent this year in the festival than ever before in the history of the institution.

LONG BRANCH, N. J., Aug. 14—An automobile parade was one of the big features of the closing day of the third annual midsummer carnival held here under the auspices of the Long Branch Board of Trade, on Saturday. Automobiles were used in the festivities to a much greater extent this year than ever before and proved to be a prime factor in each succeeding stage of the program.

During the boardwalk exercises, hundreds of cars were used to convey sightseers and when the baby parade was in progress, the procession of pretty children and their prettier mammas and nurses was reviewed from the vantage ground afforded by the parked cars.

Saturday afternoon was the culminating point in the festival and the parade of automobiles, some of them fearfully and wonderfully decorated, was the big number of the program.

At the conclusion of the parade the judges announced that the first prize for the best decorated private automobile had been awarded to Mrs. John H. Parker. The prize for original design was won by M. G. Kahn, Gimbel Brothers, Park and Tilford, Leo Metzger and Adolph Graf were other winners in the competition.

Remy Brassard Successfully Defended

BALTIMORE, Aug. 14—The Remy grand prize and brassard were successfully defended by Benz (Burman) at Electric Park Saturday on the half-mile track. The other races were won by Kline (2), Abbott-Detroit (1) and Mercedes (1).

Seven Still Perfect In Chicago Truck Run

KALAMAZOO, MICH., Aug. 15—After eight day's running the Chicago *American's* commercial vehicle reliability test from Chicago to Detroit and return there are only seven of the twenty-five starters left with perfect scores. The survivors to date are the No. 6, Hewitt; 23, Lemoon; 32, Federal; 16, Kelly; 13, Mais, and Nos. 10 and 11, Buick. The three Gramms have not been figured up as yet on to-day's run, but they have been out of the perfect score class for several days. The past week has seen some remarkable work on the part of the contesting cars. The second day's run was from South Bend to Fort Wayne, and at the end of the trip there were sixteen still perfect. There were three penalized on the run from Fort Wayne to Toledo on Thursday, five were penalized going to Lima on Friday, while Detroit was the destination on Saturday, a stop being made there over Sunday. The run from Detroit to Jackson on Monday was comparatively easy, with only one penalization. To-day, however, the run from this city resulted in seven penalizations. So far there has been only one withdrawal, the No. 9 Poss being withdrawn the end of the third day, a cracked cylinder jacket being the main difficulty. As the score stood to-night it was as follows: No. 9, Poss, out; No. 24, Lincoln, 4 points; No. 37, Vandike, 13; No. 6, Hewitt, perfect; No. 20, Bauter Jurgens, 7; No. 30, Owosso, 22; No. 38, Clark, 68; No. 39, Ideal, 7; No. 34, Chase, 4; No. 1, Gramm, 1492; No. 23, Lemoon, perfect; No. 38, Stephenson, 62; No. 32, Federal, perfect; No. 2, Gramm, not figured; No. 16, Kelly, perfect; No. 13, Mais, perfect; No. 3, Gramm, not figured; No. 14, Dayton, 30; No. 17, Kelly, 3; No. 4, Gramm, not figured; No. 10, Buick, perfect; No. 11, Buick, perfect; No. 27, Kretworth, 21; No. 31, Chicago Pneumatic, 26; No. 33, Chase, 6: No. 5, Modern, 26.

Four Road Races at Cincinnati

CINCINNATI, Aug. 14—The course selected for the Fern Bank dam road races is 7 7-10 miles in length with Cooper avenue, Blue Ash road, Montgomery Pike and Reading road making the four sides of a quadrangle. The committee has contracted for the erection of a grand stand located 12 miles from the city on Blue Ash road to seat 20,000.

The Interurban company will give the use of its car barns and machine shops at Silverton in near proximity to the course for two weeks prior to the races, insuring comfortable quarters and all necessary conveniences for repair work. The numerous crossings are to be well guarded and car service to and from the points of view will be ample.

The most valuable prize announced thus far is by The Cincinnati Automobile Club; it will be of not less than $1,000. Four races, 125, 150, 180 and 250 miles, will be run.

Where the entrants in the Chicago truck were parked overnight in Lima, Ohio

Columbus to See 200-Mile Race

COLUMBUS, O., Aug. 14—Arrangements have been completed by the Columbus Automobile Club, of Columbus, Ohio, for a 200-mile sweepstake race to be run on the Columbus Driving Park track September 3. At first the club was figuring on a number of different events for its 1911 race meeting, but after consideration it was decided to have the 200-mile contest. The contest will be a sweepstake with a purse of $1,000 to the winners in addition to $1,500 in trophies.

The race will be limited to cars having 600 or less cubic inches and the drivers who participate must reside in the State of Ohio. A sanction has been secured from the Contest Board and the representative is Mr. Grimes, of Cleveland. It is the purpose to make the meet a popular affair and an admission fee of only 50 cents will be charged. It is expected that at least 25 cars will start in the big race.

At the Contest Board the information was given that the Columbus sanction would be granted providing the track was adequately protected according to the rules.

Premier Caravan Finishes Tour

LOS ANGELES, CAL., Aug. 14—Still intact, the Premier caravan consisting of ten touring cars and two official automobiles rolled into Los Angeles last week and completed its long journey from Atlantic City, N. J. The ceremonies were finished when the front wheels of the dozen cars were driven into the Pacific ocean.

Scene in Cadillac Square, Detroit, where the Chicago truck run stopped overnight

The whole trip has been accomplished, according to those who took part in it, without resorting to anything but the power of their own motors. The schedule arranged for the tour was something in excess of 150 miles a day and the start and finish were on schedule time.

St. Louis Tour Starts West

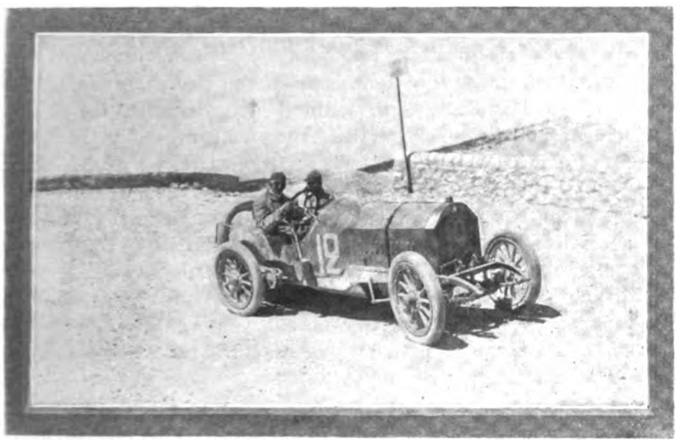
ST. LOUIS, Aug. 14—Thirteen contestants, three official cars and one non-contestant left St. Louis early Monday morning on the Manufacturers 'and Dealers' Reliability Run to Kansas City. At the time of the start it was said in St. Louis that the Kansas City motorists who had been announced to make the return trip with the St. Louisans had abandoned the plan, and the contest will be entirely a local affair. The tourists expected to arrive at Moberly Monday night, by way of Mexico and Columbia. The cars taking part are: Interstate, Dorris, Mitchell, Marmon, Ford, Ford, Ohio, Buick, Cadillac, New Parry, Flanders, Flanders, Hudson, American Traveler, Amplex, Marion and Ford.

The cars were given a rousing send off despite the smallness of the procession and at every town along the route delegations of automobile enthusiasts met the tourists and escorted them through town. Good weather was encountered and the roads were fair.

Mont-Ventoux Hill Climb

The annual French automobile classic which is held on Mont-Ventoux was a greater success this year than on any previous occasion. Several of the cars that had taken part in the recent light-car race vied with each other for fresh honors.

BEDOIN, Aug. 6—The hill which starts from here is an ideal one for a race, as it is possible from the plateau at the top to witness the cars making the arduous climb practically for the whole length of their course. Although the record for the hill was not beaten, nevertheless the time made by Deydier on the Cottin-Desgouttes was very fast. This car took part in the Grand Prix de France and it is to be regretted that the driver did not have more opportunity to study the hill as some precious time was lost on several of the turns. The Ford car, shown in the illustration, having been put in order after its accident at Le Mans, finished first in its class and second in the general classification, finishing slightly under three minutes slower than the winner. The Lion-Peugeot cars driven by the veteran pilots Goux and Boillot finished first, each in their respective classes. Gaste driving a Rossel car, who won most of the races held in the South of France last year, including the Salon meet, was unable to make good time owing to the lightness of the rear portion of the car; oftentimes the wheels spun round while the car remained stationary. The Bugatti despite a broken front spring and a burst tire managed to climb the



The winner of the Mont-Ventoux hill climb, a Cottin-Desgouttes, driven by Deydier

hill in 30 minutes, 55 seconds. The meeting was organized by the Automobile-Club Vauclusien and the arrangements were carried out without a hitch. The following are the list and times of the winning cars.

Car.	Driver.	Time.
	Sixth Class (2)	
Rossel	Gaste	23 m 34 s
	Sixth Class (1)	
Cottin-Desgouttes	Deydier	19 m 45⅗ s
	Fourth Class	
Ford	Depasse	22 m 19⅗ s
	Third Class	
Lion Peugeot	Boillot	23 m 30⅗ s

Lebanon Road Temporarily Closed

Owing to new road construction under way on the east side of Lebanon mountain, on the main route between Albany and Pittsfield, the Massachusetts Highway Commission has decided to close the road for several weeks.

State Officials to Inspect Roads

One of the most important conferences in the interest of highway improvement that has ever taken place in the East, will be held within the next fortnight, when the highway officials of New York, Massachusetts and Connecticut will make a tour of inspection over some of the more important roads of their respective States.

The details for this conference are now being arranged by the Touring Club of America. The New York delegation will meet at Albany and from that point the motor tour will be made to Pittsfield and thence to Springfield, Mass., where the general conference will be held.

Hupp Sells Stock in Motor Company

DETROIT, MICH., Aug. 15—Robert C. Hupp, president of the Hupp Motor Car Company, of which he was also organizer, yesterday disposed of his stock to a number of the present officers of the company and will on September 1, cease all connections with it.

Until that date he will retain his offices of president and general manager, although practically all of his time will be devoted to the affairs of the Hupp Corporation, a collection of manufacturing plants in Fairview east of Detroit.

Mr. Hupp's retirement from the affairs of the Motor Car Company has been rumored for some time but has been categorically denied by both himself and by the officers of the company.

Local gossip is now busy with the future plans of the Hupp Corporation. It is freely rumored that it will soon add to its products a gasoline car of light type, on lines somewhat similar to those of the Hupmobile. Mr. Hupp refuses to discuss this matter aside from authorizing the statement that the Hupp Corporation is now fully equipped to build any sort of automobile product. Prior to his organization of the Hupp Motor Car Company, which has been a marked financial success, Mr. Hupp was connected with the Oldsmobile Company, both at Detroit and Lansing.

Briscoe Predicts 210,000 Cars for 1912

Benjamin Briscoe, president of the United States Motor Company, has declared in an authorized interview that the production of passenger automobiles in 1912 will in his opinion reach the record-breaking total of 210,000 cars. He states that he believes that fully 60 per cent. of this number, or 126,000, will be required to fill the demands of physicians, contractors, salesmen, etc., who use their automobiles in business and pleasure.

Mr. Briscoe estimates that the average cost will be reduced from $1,533, where it stood last year, to about $1,100. This would indicate a largely increased production of cars selling under $1,000. In his figures Mr. Briscoe does not include trucks.

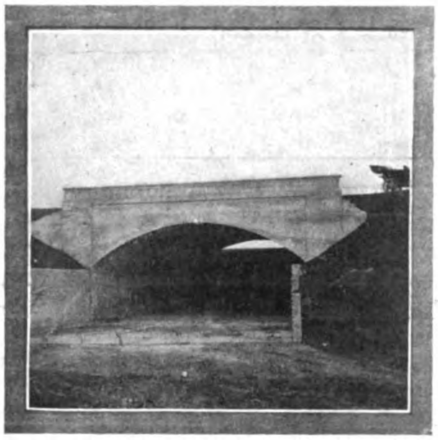
Oklahoma City Shows the Way

Cow Town Is Building Vast Park Speedway

America's newest metropolis, Oklahoma City, is completing a speedway boulevard project that makes anything else of its kind in the world look like a counterfeit. The course is almost finished and when the last touch has been added the course will be twenty-six miles long, surrounding the city with a ninety-foot speedway without a single grade crossing, smooth as to surface and absolutely protected throughout its length. Already plans are being made to run off some of the motor classics on the new course before cold weather sets in.



Side view of one of the arches over a "fill"

OKLAHOMA CITY, OKLA., Aug. 14—Oklahoma City is spending a half million dollars in constructing an automobile boulevard, approximately 26 miles in length, and a system of public parks. Plans are being discussed by the local and State automobile associations for holding races which will attract the attention of the speed demons from all parts of the country, because of the excellent opportunities offered on the course for smashing records.

The route of the boulevard circles the city in a rectangular manner, 6 miles to the side, with half-mile curves at the corners. The heaviest grade is approximately 3 per cent. for a distance of a little more than 900 feet. All grade crossings have been eliminated by subways and the ravines through the parks are bridged with concrete arches.

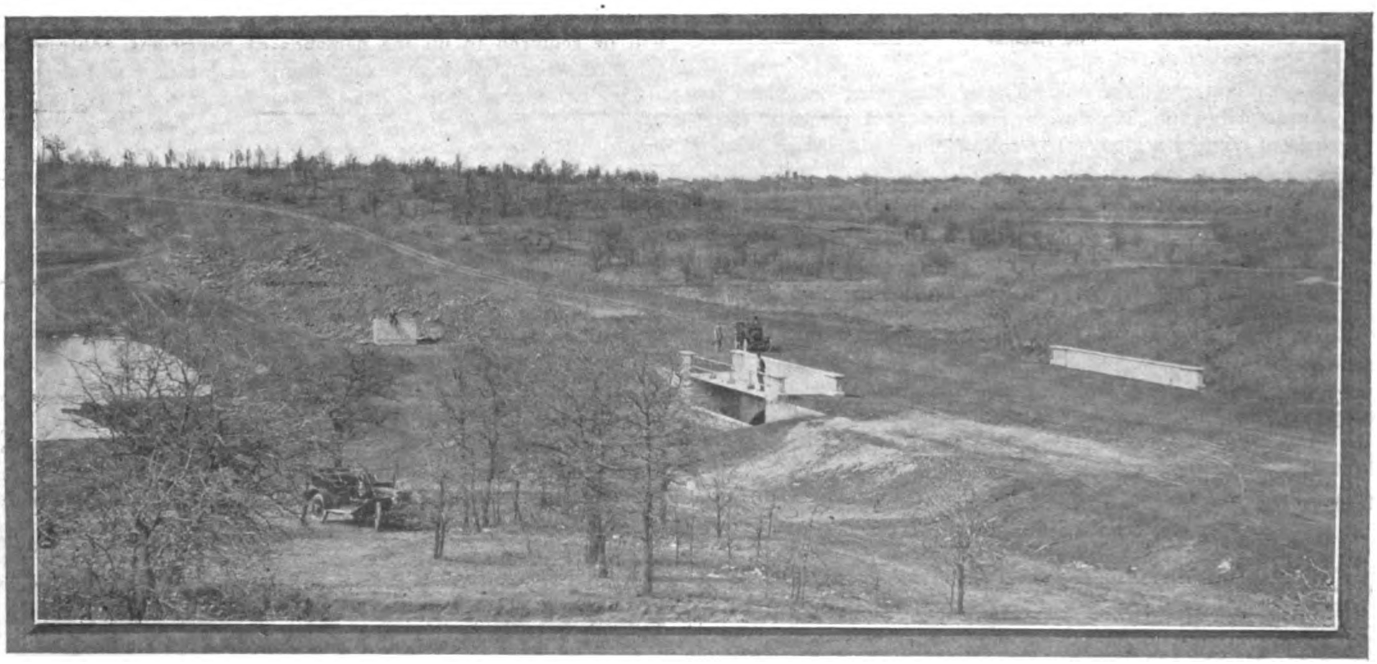
The speedway proper is 90 feet wide. On either side are driveways for carriages. At different places these cross and recross to opposite sides of the track by subways. At no place do they cross a grade, thus eliminating the possibility of the fatalities of road races.

Twenty-one miles of the main drive have been completed, so far as grading, construction of bridges and elimination of sharp curves are concerned. The remaining portion of the track is being held up pending adjustment of little details as to the right-of-way through a school-land section. The dust is to be laid and packed with oil.

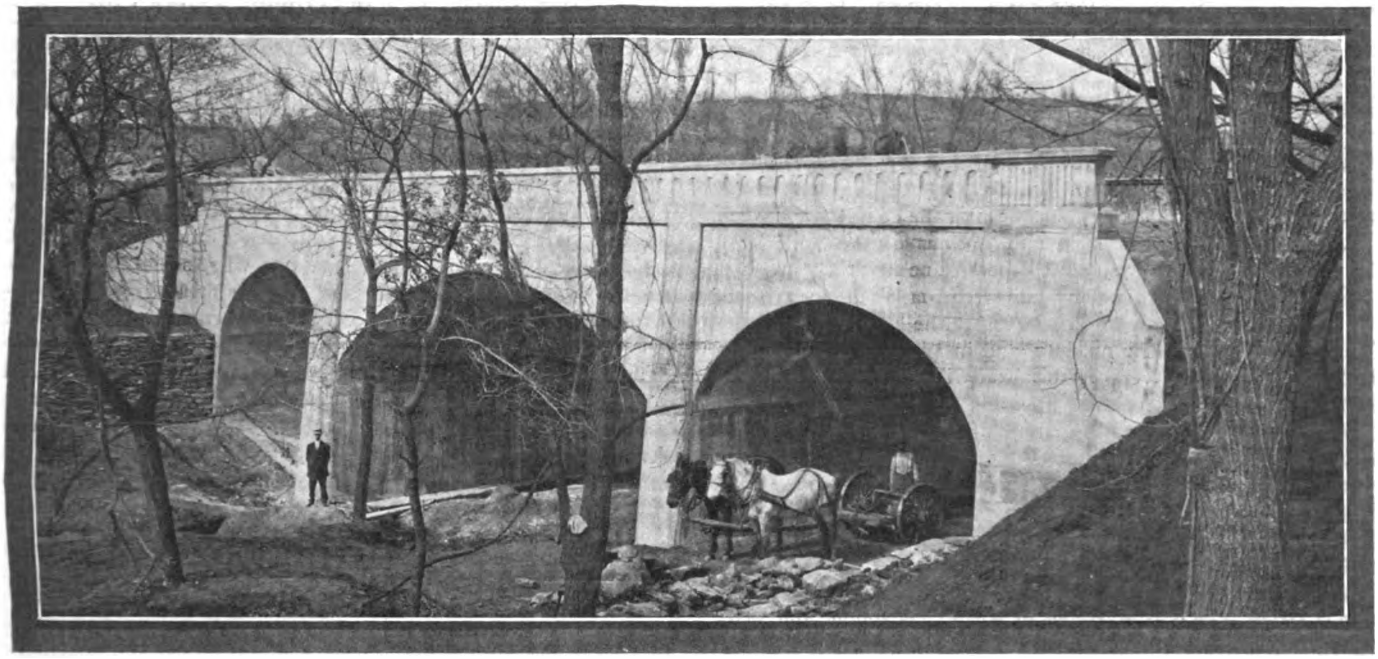
When completed the track is expected to be one of the fastest and least dangerous of the inland race courses, combining the possibilities of the straightaway and the road race course with sharp curves, steep grades and grade crossings eliminated.

Constructed under the supervision of the city park commission, the boulevard is being built with all consideration for the development and bringing out of nature's beauty spots along the route. Four large park tracts have been acquired at the northeast, northwest, southeast and southwest corners of the boulevard system, consisting of approximately 1,600 acres. A lake of 60 acres has been created at the northeast park. A second of 70 acres is to be built at the southeast corner. Property owners at various points have donated smaller tracts for park purposes at various times until the city now has more than twenty-five parks with a total estimated value of more than $1,750,000, obtained at a total cost of $209,319.17.

A preliminary bond issue of $400,000 was voted in 1909 to



View of the 26-mile automobile speedway at Oklahoma City. All grade crossings have been eliminated and one 3 per cent. incline is the steepest



Triple-arched bridges span the streams and form subways for carriage driveways at the right and left

begin the work. Property adjacent to parks, valued at $500,000, is now held by the commission, and is ready for the real estate market, all of which was obtained by donations and financiering by the board in the purchase of the property for the right-of-way. The value of the land obtained as a side issue to the proposition has more than paid for the first series of bonds.

One of the most beautiful parts of the course is the portion passing through the northeast park. It passes over the dam in a roadway 40 feet wide. The dam is 1,100 feet long and 44 feet high. The spillway is 40 feet wide, covered by a reinforced concrete arch. The driveway is 60 feet wide between the balustrades, accommodating both the auto course and one carriage driveway.

On the north line is an unique structure consisting of a 5-foot culvert over which is constructed a 20-foot bridge or subway, the design being intended to allow the ordinary drainage to pass through the culvert and the heavy floods to flow through the 20-foot bridge. The bridge also serves as a connecting driveway between the two carriageways under the auto course. Just east of this combination bridge and culvert is another curious bit of construction work. The speedway passes over a deep ravine, just above a rocky waterfall. A concrete slab was constructed from one bank to another so that there is apparently no bridge. On one side is the effect of a shallow valley and a 50-foot ravine on the other.

The greatest opposition met by the commission in obtaining the right-of-way was from school-land lessees. They opposed the boulevard, giving as their reason that it would enhance the value of the land very materially, thus causing them to pay more for it when it is placed on the market. Appeal was made to the Legislature for relief and it responded by authorizing the sale of the school sections adjacent to the city property.

Contracts for the first grading were let in February, 1910, when work was started on 12 miles of the speedway. Dedication of the opening of the first 17 miles completed was marked by an automobile parade of more than 200 machines. Diagonal boulevards extending from the central portion of the city to the outer or Grand Boulevard are to be constructed. The routes outlined for these as well as practically all parts of the speedway afford a splendid view of the city.

The four sides of the boulevard are distant from the present business center substantially 3 1-2 miles to the north and 3 miles to the east, south and west. The circumscribed territory (about 46 square miles) will accommodate only 184,000 persons, figuring on a basis of 4,000 inhabitants per square mile; so it will appear that Oklahoma City is making a wise move in obtaining these valuable bits of land for the speedway and park and parkway purposes while it has a population of only 65,000 and is still the largest city in the State.

Wisconsin Adopts State Aid

MILWAUKEE, Aug. 14—"The knell of the road working picnic has been tolled. We have passed the day when the working out system of road taxes is advisable or feasible. Wisconsin has joined the ranks of the progressive States which have by systematic work produced admirable systems of highways."

In these words John A. Hazelwood, of Jefferson, Wis., former State Senator and chairman of the Wisconsin Highway Commission, created by the 1911 Legislature, sounded the keynote of the board's future activities in an address before the Dodge County Board of Supervisors at Juneau, Wis., last week. It was the first public statement by a member of the commission and formally introduced State aid for highway construction.

Acting under the new law appropriating $350,000 each year to counties which expend an amount equal to their respective apportionments, the Dodge County board has already started a constructive program, being one of the first counties to take advantage of the new act.

"This State has practically stood still in the matter of building permanent highways," said Mr. Hazelwood. "On the other hand, 75 per cent. of the States of the Union have made marked progress. Central governments all over the world have generally employed the policy of State or Government aid. Most States have adopted some form of a State aid policy. For liberality we have been far outdone in Wisconsin by Minnesota on the start. Money invested in improvement of highways is like 'casting bread upon the waters.'

"One of the most pleasing features of the new Wisconsin act is that it provides a fine example of the initiative. It is up to townships or public-spirited citizens to ask for road improvement. And to those that ask will be given."

Up to this time roads have been built in a haphazard manner. A farmer could work out his poll tax by putting in one day on the highway. One or two farmers went on the road with teams and did more damage than good. All of this work is now stopped and a systematic program substituted.

Clans Gather for the Elgin Races

CHICAGO, Aug. 14—The racing clans are gathering for the American Automobile Association's national stock chassis road races which will be run at Elgin August 25-26. Several have been in camp for a week past, but the bulk of the drivers get there this week. The Alco team has been at the course for a week now, Maisonville of the Corbin and Jeffkins of the Velie have been out there several days, while others came in to-day.

Official practice starts Friday and from 11 a. m. to 1 p. m. each day the throttle can be opened under the supervision of the officials. Flagmen will be on duty, and in addition three officials of the Motor Race Drivers' Association will be present to superintend the practice. It is the intention of the Chicago Motor Club to have a medical examination of the drivers and if any of them are deemed incapacitated they cannot start.

Only one entry has come in since last week. The Ford Motor Company has nominated a car for the Aurora cup with Frank Kulick to drive. Now there are thirty-three entries in the four events. In the Elgin National for the under 600 class there are: Mulford in a Lozier; two Nationals, drivers unnamed; Grant, Lee and Hartman in Alcos; De Palma and Wishart in Simplexes; Buck in a Pope-Hartford; Hughes in a Mercer, and Burt in a Cino.

The Illinois cup race on the first day, for the 301-450 class, only has four named so far, two Nationals and a pair of Velies, with Stickney and Jeffkins as the Velie drivers. In the Kane County cup for the 231-300 class, there are three Falcars, three Stavers, three Colbys, two Coles, two Mercers, two Cinos and a Corbin. The Aurora cup race for the 161-230 class has in it an Abbott-Detroit to be driven by Mortimer Roberts and a Ford to be handled by Frank Kulick.

Additions to the prize list have been made by the accessories people and now there is hung up a total of $5,250 exclusive of the cash offering of the Elgin Automobile Road Race Association, $2,500. The Remy Electric Company to-day gave $1,200 conditional on the winners using Remy ignition, $250 for first, $100 for second and $50 for third being offered in the Elgin National, Illinois and Kane County. The Dorian Demountable Rim Company is offering $250 to the first man finishing on Dorian rims in the big race, $150 for the first one in the Kane County and $100 in the Illinois. The makers of the Sears & Cross type of speedometer will give $200 to the users of their device.

New Knox Water-Tower Tried Out

Springfield, Mass., had its first glimpse of an odd-looking piece of fire-fighting mechanism the other day when the new Knox water-tower, designed by Charles H. Martin, was tried out in the vicinity.

The device consists of a steel frame, carrying a motor and transmission machinery which is placed in front of a fire engine, or other apparatus, designed to be horse drawn. It rests on the front axle of the vehicle to which it is attached. In front it is supported by a single wheel, or two wheels placed close together. This construction gives it a more or less freakish appearance, but is said to be necessary in order to make short turns and handle the vehicle in narrow streets.

The frame is supported on easy springs in both front and rear, which prevents the engine and drawing mechanism from being shaken to pieces on rough roads. The engine is geared by means of chains and sprockets to the front wheels of the vehicle, the whole making a complete motor-drawn piece of fire-fighting apparatus.

Mead Temporarily Heads General Motors

DETROIT, Aug. 14—An event of general interest throughout the trade is the departure of President Neall of the General Motors Co. to Europe on a prolonged trip.

During his absence the affairs of General Motors will be managed by what is known as the "President's Council," of which W. J. Mead, vice-president of the company and manager of the Oldsmobile plant, is chairman. Mr. Mead will move his headquarters to Detroit during Mr. Neall's absence. The other members of the council are Gleeson Murphy, assistant to the president; treasurer, James T. Shaw; secretary, Standish Backus, and director of production, Tracy Lyon.

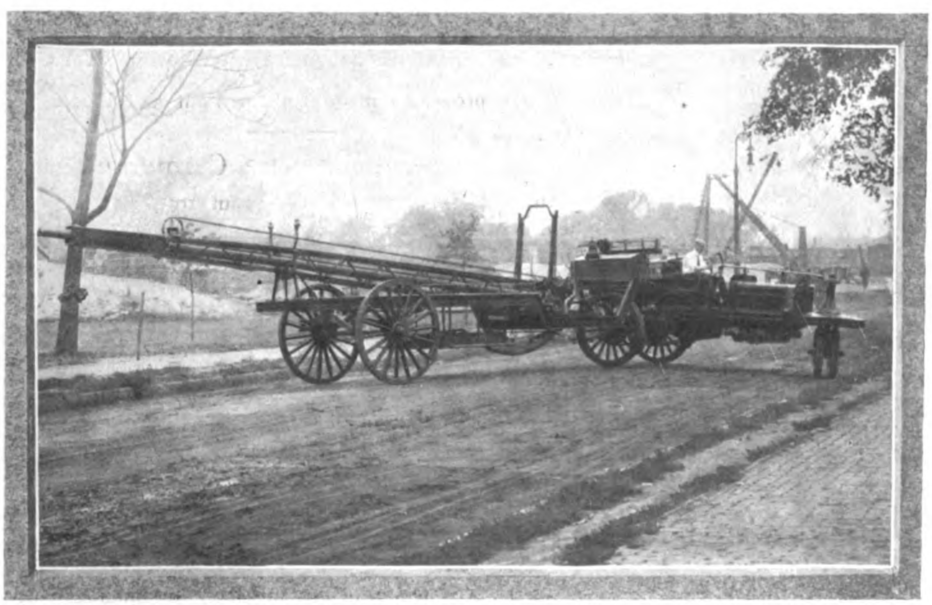
Rebuilding Old King's Highway

SANTA BARBARA, Aug. 14—One of the most unique good roads campaigns ever conducted in this country is at present being waged there. It has as its object the raising of the sum of $100,000 for the construction of what will be known as the Rincon road.

The Rincon will be a sea-level road, from Ventura to Carpinteria, 12 miles south of here, shortening the distance along the coast road 9 miles and, what means more, overcoming the dangerous Casitas pass.

This pass is one of the dangerous features of the coast highway. It has many turns. The road is narrow and is impossible to keep in fair condition at all seasons of the year. To a tourist who is not thoroughly familiar with it danger lurks at every turn.

Half of the money needed is being raised by voluntary subscriptions, and the main campaign is being conducted from here, the Santa Barbara Chamber of Commerce having taken the initiative. Acting on the most important sub-committee are Milo M. Potter, proprietor of the Potter Hotel; Louis Jones, president of the Chamber of Commerce, and Phil H. Rice.



Water tower, with Martin tractor in front, recently built by the Knox company for the Springfield, Mass., fire department

$1,000,000 Company to Make Motors

FLINT, MICH., Aug. 14—The Mason Motor Company has filed articles of incorporation with the Secretary of State.

The capital stock is $100,000. All of the capital stock has been paid in, it is reported.

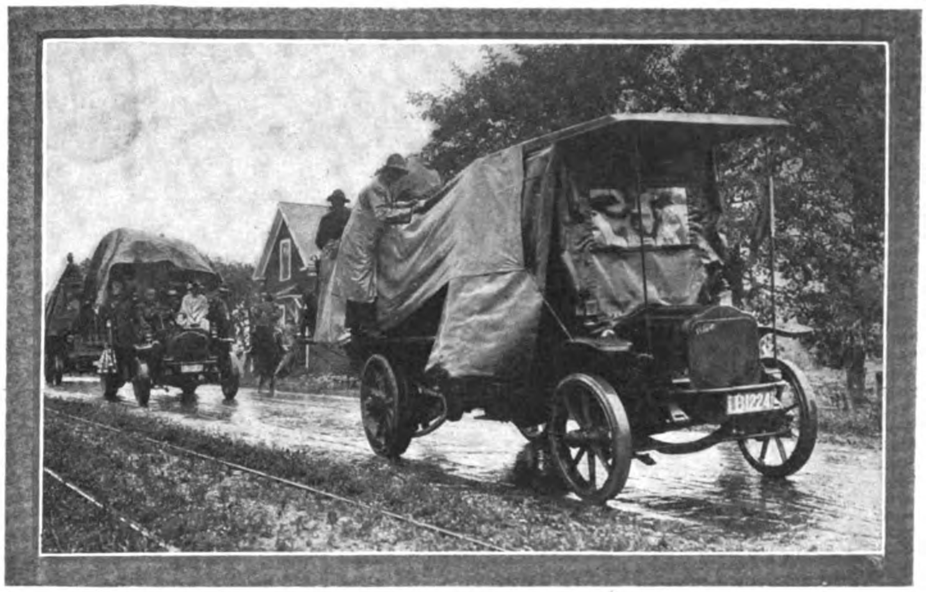
The new concern will engage in the manufacture of engines for automobiles and plans have been made for carrying on the business of the company on an extensive scale.

The company has closed a two years' lease of a large four-story building in the Fourth ward, adjoining the Flint wagon works, which will suitably lend itself to the purposes of the new company. The building is 85 x 65 feet and has a flood space of about 5,500 square feet.

The plant will be ready to begin operations in about two weeks and it is expected that by next spring it will give employment to at least 500 skilled mechanics. The capacity of the plant will be forty engines per day.

The Mason company will make engines for the new Chevrolet cars, which are to be built in Detroit until a permanent site for the Chevrolet Motor Company's plant is selected.

The principal incorporator of the new company is Arthur Mason, of Flint, who will have entire charge.



Part of the battery of White trucks which took care of the transportation end of the recent maneuvers of the Massachusetts militia

Six-Cylinder Knight Introduced in America

The 1912 announcement of the Stoddard-Dayton car brings forth the fact that the six-cylinder Knight with the cylinders cast in groups of three has found its way into this country. The practice of casting the cylinders in groups of three has been in vogue in Europe and it has been found that with the seven-bearing crankshaft great rigidity can be obtained.

While the anouncement of the 1912 Stoddard-Dayton cars includes twenty-five different models, there is one type which perhaps will excite as great an interest as any of the products brought out during the present year, since it embodies the introduction of the six-cylinder Knight motor to America.

This motor is placed in six different types of bodies; a seven-passenger touring, seven-passenger limousine, and six-passenger torpedo. The same chassis reduced to a wheel base of 122 1-2 inches is adapted to a four-passenger torpedo or a two-passenger roadster.

Convenience has been made an aim by providing large and water-tight baggage compartments on the roadster, which can conveniently carry two large suit cases.

Midsummer Show Is Planned

Des Moines, Iowa, Aug. 14—Des Moines automobile dealers will hold a big automobile show in connection with the Iowa State fair, the last week in August. W. E. Moyer, president of the local dealers' association, C. G. Van Vliet, secretary, and George Harritt are in charge of the affair and 30,000 square feet of floor space has been reserved by the local dealers. A big floral parade is to be pulled off August 26.

Receiver for Fal Company

Chicago, Aug. 12—The Fal Motor Co., of Chicago, maker of the Falcar, went into the receiver's hands to-day when Referee in Bankruptcy Wean named Edward C. Day, a lawyer, as receiver. The application was made by a creditors' committee consisting of H. K. Gilbert, of the Buda Co., A. H. D. Altree, of the Bosch Magneto Co., and H. H. Seaman, of the W. S. Seaman Co. The value of the assets is placed at $75,000 and the liabilities at $150,000

Just what the receiver will do has not been determined. An inventory is being taken now and when that is completed a policy will be outlined. However, it has been determined to finish up the cars now on hand. The creditors' committee has made a statement relative to the receivership appointment.

Trucks Take Place of Wagon Train

Among the trucks used in connection with the recent maneuvers of the National Guard of Massachusetts were a number of standard types of three-ton capacity. The trucks, numbering about twenty, were used by the troops in place of the antiquated wagon train of other days. The trucks did the work of fifty or more wagons and demonstrated that the automobile is vastly better adapated to this sort of work than the horse-drawn wagon. There were five Whites and several Kissel trucks.

Axle Plant Much Enlarged

Jackson, Mich., Aug. 14—The new Lewis Spring & Axle Company plant, Horton street, is nearing completion. It will afford employment to about 200 additional men. The Park avenue plant of the company will be vacated upon the occupancy of the new building.

The new factory is 250 feet square and has a total floor space of 62,500 square feet. It is a one-story structure of light red brick with ample provision made for fine light and ventilation

Mitchell Agents Prepare Campaign

Racine, Aug. 14—On August 11-12 about 100 agents of the Mitchell held a reunion at the factory of the Mitchell-Lewis Motor Company, Racine, Wis. They inspected new models and lined up a campaign for the coming year under the direction of Wm. L. Day, general sales manager.

Shiland Takes Hold of Westcott Sales

Richmond, Ind., Aug. 14—H. E. Shiland has been appointed general sales manager of the Westcott Motor Car Company. Mr. Shiland was formely sales manager for the Buick Motor Company.

Will Sell Matheson Cars

Wilkes-Barre, Pa., Aug. 14—The Matheson Automobile Company, of Wilkes-Barre, announces the appointment of H. De Long Fry, of Albany, N. Y., as assistant sales manager.

New Things Among the Accessories

Gasoline Economizer and Filter

PERFECT vaporization of the gasoline used as fuel in internal combustion engines is an absolute requirement for success along this line of endeavor, and while this need is recognized by all engineers there are many of them even to-day who look at an incomplete evaporation as a necessary evil that there is no way to avoid. The cause of inefficient vaporization lies often in the construction of the carbureter nozzle, resulting in a thin and straight jet rather than the formation of a broad cone of gasoline-air mixture. While a good deal of gasoline is vaporized even by the nozzle termed inefficient, the gasoline is not torn up in globules small enough not to accumulate in drops when striking the metal surface of the manifold. Under the circumstances it is even difficult to prevent liquid gasoline particles from entering the combustion chamber, where it has to be vaporized by the engine heat of combustion, thus detracting from the useful work of the machine.

In Fig. 2 is shown the proper way of atomizating the gasoline, which, when leaving the nozzle, is torn up into infinitely small particles and by centrifugal action made to form a cone-shaped mist. At (B) the effect of a straight-jet nozzle is shown, and while the illustration may be somewhat exaggerated it serves well to bring out the difference of the two principles. The reason for this difference in action lies in the manner of construction of the two nozzles used, and, broadly speaking, the pressure under which the liquid is expelled through the nozzle orifice. As will be seen, the pressure is much higher in the case of the conical spray than where the straight jet is formed.

The conical spray here reproduced has been obtained by the use of the Mills petrol economizer and filter, three views of which are shown in Fig. 3. At (A) it is seen how the economizer is made so as to screw into the passageway leading from the float chamber to the vaporizing space, while (B) illustrates the arrangement of the economizer for use in the well-known Longuemare carbureter. The economizer B having an outlet A is fitted in the vertical continuation of the passageway H by the use of a flange D tightened by the leather washer E which prevents the gasoline from flowing upward through the holes G. F is the economizer inlet. The construction of the device itself is brought out in (C) where D is a stationary nozzle located inside the outer nozzle A1. The adapter A which helps to fit the economizer in a carbureter instead of the nozzle furnished therewith contains a wire-gauze filter which keeps all foreign matter from entering the inner economizer space B. After passing through this filter, the gasoline flows up through the tube D, leaving it through two skew holes at the top. By this arrangement the liquid is made to swirl before it leaves through the orifice C, and this revolving motion in addition to the high pressure created by the use of the cylindrical space C results in centrifugal action which throws the gasoline out toward the sides of the nozzle, causing it to form the conical spray on account of its being mixed with the atmospheric air.

The economizer and filter is made by H. E. Mills, 441 Brighton Road, S. Croydon, Surrey, England, and is applicable to the use of gasoline, benzol or paraffine. The size of the engine may necessitate an enlargement of the orifice C, but in making this adjustment care must be taken so as to make the hole not too wide, since this would tend to destroy the conical shape of the gasoline-air jet and to form a straight jet, thus robbing the device of one of its most valuable features.

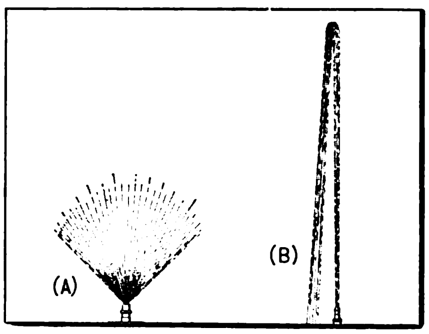


Fig. 2—Gasoline atomized spray and straight jet

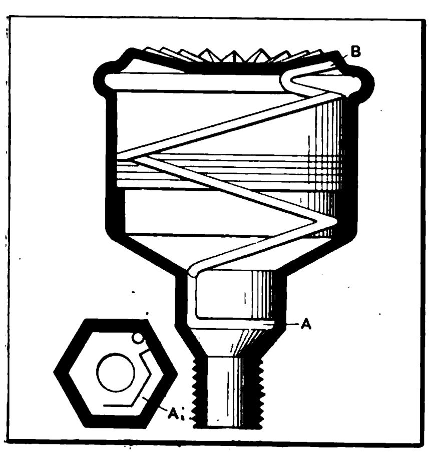

Fig. 1—Merchant & Evans securely fixed grease cup

Securely Attached Grease Cup

MANY parts of the automobile are lubricated by means of grease cups which are filled with the lubricant and then left in place for a number of days or weeks. This makes the method of lubricating such parts a very comfortable matter, or would make it one were it not for the fact that in course of time the caps of grease cups tend to come off and that, therefore, it will be necessary for the automobilist to inspect, at frequent intervals, the places so lubricated, only to find out whether the grease cups are still in place.

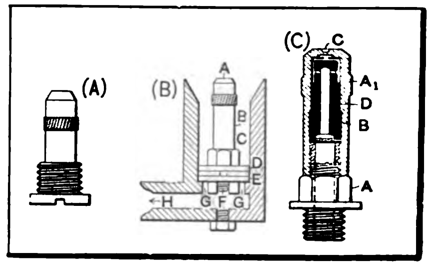

Fig. 3—Details of Mills Economizer and Mixer

To relieve a strained situation, an attempt has been made to construct a cup that won't come off, which is shown in the accompanying Fig. 1, it being a product of the Merchant & Evans Company, of New York, Chicago, etc., known as manufacturers of transmissions, alignment joints and so forth. The grease cup mentioned contains a spiral wire, as may be seen from the illustration, one end of the wire is hexagonally shaped, fitting in the hexagonal shank shown at A, its form positively preventing it from turning.

The other end of the wire is made to act as a pawl. Looking at the top of the cup reveals a corrugated surface, and the end of the spring B engages with this corrugated surface, but does not interfere with the screwing down of the cap. Turning the cap causes the wire end to slip from one corrugation to the other, holding at the same time the cap in secure relation. As the wire is spiral in shape it serves as a spring holding the pawl end firmly against the top of the grease cup. The operation of this type of cup if exactly the same as that of any other kind, by means of the fingers of one hand, the interior wire mechanism adding no complication to the handling of the device.

Solderall Compound

SOLDERING is an operation which, according to general belief, requires a very hot flame, a blow-torch and considerable skill to get up a good connection between two pieces of metal, but there has appeared on the market a pure tin solder which permits of soldering without the appliances heretofore considered absolutely necessary for doing this work. The tin contained in Solderall, as the compound is named, is combined with a non-corrosive flux having the consistency of a paste, which melts at the low temperature produced by a burning match. After cleaning the metal surfaces to be soldered from the oxide, which always covers such exposed parts, a little paste is smeared over them, and after placing them together in the position that they are desired to hold after

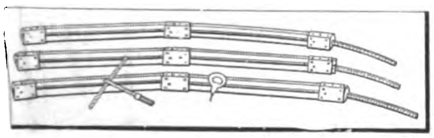

Fig. 4—Elements of the Fudge emergency tire

soldering, heat the parts covered with the paste by means of a match, a candle or a torch. The special composition of the solder assures its melting within a few seconds, after which the metal parts are allowed to cool off. A test made will show that the work has been done efficaciously, and the solder will be at least equal in strength to the component members. This solder is made and marketed by the H. W. Johns-Manville Company, of 100 William street, New York.

Sectional Emergency Tire

IN Fig. 4 the elements of the Fudge Emergency Tire are illustrated, and, as the cut shows, they are in the shape of flexible but solid strips of material, being capable to be connected up by the operation of a simple mechanism. A flexible rack is securely fastened to one end of a tire element, while the other contains a guideway for the rack. This guide contains another rack meshing with the teeth of the rack first mentioned, and also with a pinion stationed in the center of the tire element.

If it is desired to mount the Fudge which is applied over the regular pneumatic tire, the three elements are connected by means of the racks, leaving the tire ring open in one place, as indicated in Fig. 5. Then the emergency tire is placed on the floor, taking care to get no grease on the emergency tire, since this substance does it no more benefit than it renders a pneumatic. The wheel on which the Fudge tire is to be mounted is then rolled on the emergency tire, until the position illustrated in Fig. 5 is reached. Thereafter the opening between the two tire elements shown in the figure is closed up by locking the two racks, and to tighten the elements of the tire against each other the pinion wrench shown in Fig. 4 is used. The wrench is inserted into the opening located in the center of each element, and since it fits the hub of the inner pinion it is possible to turn the latter by means of the wrench, thereby bringing the two racks into closer engagement. This procedure is continued until the ends of each two elements meet, when sufficient tension will obtain. In order to remove the emergency tire from the wheel the release pin seen in Fig. 4 is used. For this purpose the pinion is given a short turn with the wrench, tightening it a little, and then the release pin twisted as far as possible toward the pinion; thereafter the wrench is made to turn the pinion in the opposite direction and promptly unlocks the racks it controls.

While the two illustrations here given are of the three-section type of emergency tire, the Fudge Brothers Manufacturing Company, of Marion, Ind., also make a two-section and a four-section type, the operation of which is identical with that of the three-section class.

Auto Heel Rest

FATIGUE is the demon that interferes with efficiency in personal work, and to increase efficiency some men directing manual or, speaking more generally, cor-

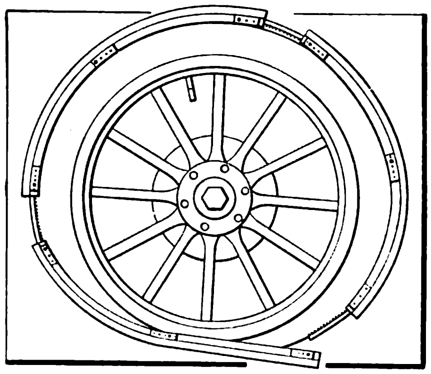

Fig. 5—Mounting the Fudge on a pneumatic tire

poral labor, have found it of advantage to make a study of the motions of which the operations of the laborers are composed. It is the useless strain that brings about early fatigue and, remembering that the chauffeur, who is bound to keep his foot on the pedal when driving, does the work with his sole, it would be a step in the right direction were he to be freed of the hard work of pressing his heel against the floorboard without finding a positive fulcrum.

Recognizing the reduction of the useless strain on the chauffeur if his heel is afforded a positive resting place, L. Lucas & Son, of 3 Fox street, Bridgeport, Conn., have constructed and placed on the market the simple and practical footrest which is shown in Fig. 6. The footrest here illustrated is cast of aluminum and in the shape of a rectangular prism, 4 inches long by 2 1-2 inches wide, and about an inch high. There is no baseplate, but in-

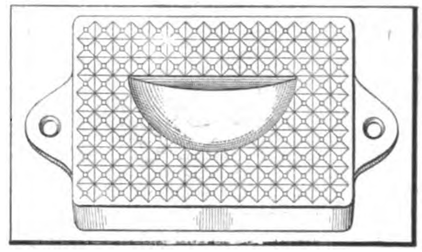

Fig. 6—Auto heel rest, which is cast of aluminum

stead of it two flanges are cast integral with the two vertical sideplates, permitting the footrest to be attached to the footboard by means of two screws and nuts. The footrest is preferably attached so that the foot poised on the cavity of the footrest in in position to operate the accelerator. In addition to giving the heel a strong hold, the Auto Heel Rest brings the foot higher up, which permits the driver to work with his foot with less strain on the muscles of his leg, thereby protecting him from unnecessary and early fatigue in driving.

Coupling the Magneto to the Drive

THE coupling illustrated in Fig. 7 consists of two parts, one being cone-shaped with a crown end, while the other is a cross-piece of special construction. The crown carries two diametrically opposed slots which are lined with fiber. In these slots fit the ends of the cross bar, which on examination is found to consist of a great number of laminations of fine spring steel. By virtue of the spring the looseness and pounding, which may be produced with the ordinary coupling under varying resistance to the rotation of the armature, are entirely absorbed and the armature, in consequence, runs with much greater smoothness than is obtainable with any former type, and with absolute silence. Furthermore, there is sufficient spring in the cross section of the laminations composing the cross-bar to permit the magneto to run with the armature shaft at an angle with the drive shaft.

The coupling thus becomes a universal joint, for it not only gives a drive with the two shafts off center, as is the case with the ordinary Oldham coupling, but in addition permits the shaft to run out of line. This coupling is made by the Bosch Magneto Company, 225 West 46th street, New York City.

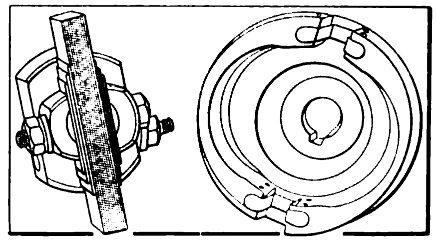

Fig. 7—Bosch coupling for driving the magneto

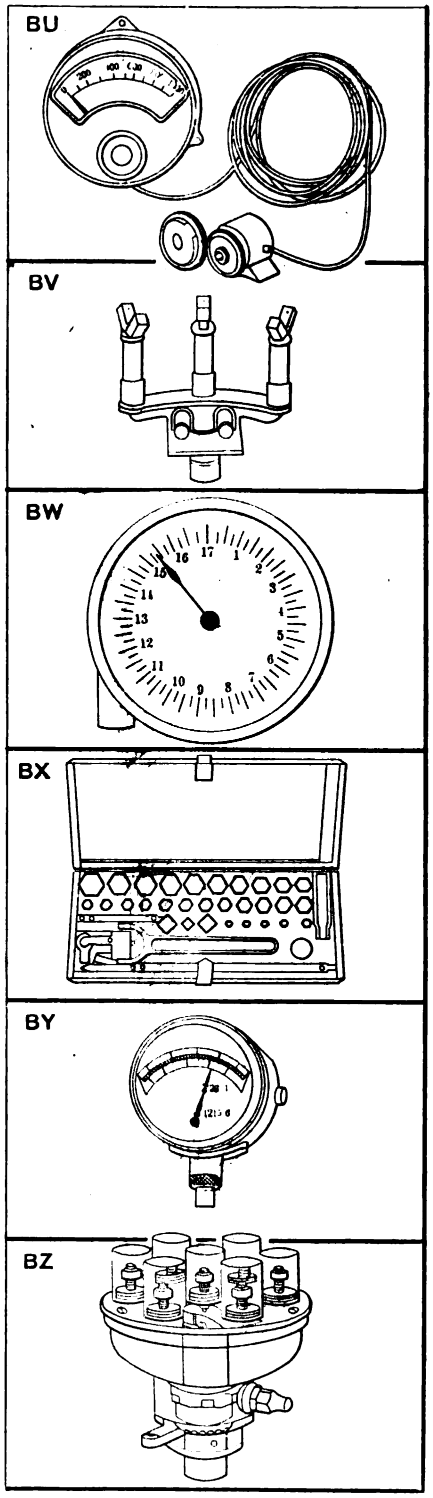
Seen in the Show Window

PRECISE measurements are at the foundation of standard methods of production, and they are applied not only to the material as it is worked into the machines being made, but the power output and its component factors are also submitted to a series of exacting tests. The tachometer, shown at BU, is built for exact measurements of the engine r.p.m. and consists of a dial upon which the speed of the engine is indicated, the operation being similar to that of an electric meter. To measure motor speed, the part of the tachometer, which is connected to the dial by insulated wiring and which contains a small direct-current magneto, is applied to the engine to be tested in the usual way. The strength of current in the magneto varies directly with the engine speed actuating the magneto, so that correct readings are obtained for all the r.p.m.'s indicated on the dial. It is made by the Electric Speedometer Company, of Washington, D. C.

OBVIOUS advantages accompany the use of acetylene in automobile illumination; brightness and cleanliness are the principal virtues of this system hardly to be surpassed for effectiveness. The Tri-Radiant burner BV is so constructed as to light the road in front of a car as well as the fields alongside of it. A triple burner, of which this lighting system has derived its name, produces enough light to brightly illuminate the road as well as the portions of the land neighboring it, the effect of the triple burner being assisted by a system of lenses which properly distribute the light. This type of burner is handled by the Lenhart Manufacturing Company, Inc., 246 North Delaware avenue, Philadelphia, Pa.

LIMITED as the supply kept in the gasoline tank must necessarily be, it is bound to give out at some time or other, and the automobilist generally finds himself in an out-of-the-way locality when the emptiness of the tank manifests itself. To avoid such a situation a gasoline gauge will be a useful accessory to install on an automobile. In this connection the Smith gasoline meter, shown at BW, is interesting. Placed on the dash, in a conspicuous position, it shows at all times how much the tank contains, and an occasional look at it will keep the driver out of such a disagreeable situation as getting stalled on a hill, miles away from the nearest garage. The gauge fits all makes of cars and is guaranteed for two years by the Smith Gasoline Meter Co., 1777 Broadway, New York City.



BU—Electric Speedometer Company's Tachometer for measuring engine speed
BV—Tri-Radiant acetylene has wide range and great illuminating power
BW—Smith gasoline gauge saves trouble arising from an empty fuel tank
BX—Bay State autokit overcomes stubbornness of standard-dimensioned nuts
BY—Sears-Cross speedometer opens the driver's eyes in regard to his speed
BZ—Leavitt distributor simplifies internal-combustion ignition systems

INACCESSIBILITY of nuts is a derogatory feature of chassis construction, but it stands to reason that to get at these unruly portions of the automobile's mechanism is no more difficult than to screw them on. It is only a matter of having and using the right kind of tool, and a normal amount of mechanical skill will suffice to get at and remove the nut in question. In the Bay State Autokit, which is illustrated at BX, a substantial wrench is contained, together with the necessary fittings to give it a solid grip on all standard-dimension nuts. The equipment is handy and takes up little room, being enclosed in a flat case, and is sold by Geo. A. Cutter, Taunton, Mass.

IT is of great importance for the driver to always know the speed at which his car is traveling, and speedometers are today part of the equipment of practically all cars in operation. One of the popular types is here shown (BY); it is made by the Sears-Cross Company, of 687 Eleventh avenue, New York City, in five styles. There are no magnetic parts contained in this speedometer, and its operation is purely mechanical, so that it may well be expected to work correctly under all weather conditions. As the illustration shows, the dial contains a speed indicator, showing the velocity up to 60 miles an hour; also a trip mile indicator, which may be set to zero at the will of the operator, and the "total" mileage indicator, showing the number of miles traveled by the car since the installation of the speedometer which is placed on the dashboard.

THE early introduction of multiple-unit coils is largely responsible for their being found in far more ignition systems than are distributors combined with single-unit coils. This statement is proved by the fact that owing to the merit of distributors these are continually being used, and to some degree, increasing in numbers, and are giving satisfactory results. The Leavitt Improved Distributor (BZ) is made to work on from ¼ to ½ ampere current, while the timer vibrator can be adjusted to take from 1½ to 2 amperes. As a result of these excessive burning is caused at the contact points. In the Leavitt the points are made of iridium, an inert metal subject to no chemical changes in consequence of the electric strains placed on it. The distributor here shown is made for engines with any number of cylinders, from two to eight, by the Uncas Specialty Company, of Norwich, Conn.

VOL. XXV NEW YORK—THURSDAY, AUGUST 24, 1911—CHICAGO No. 8

THE AUTOMOBILE

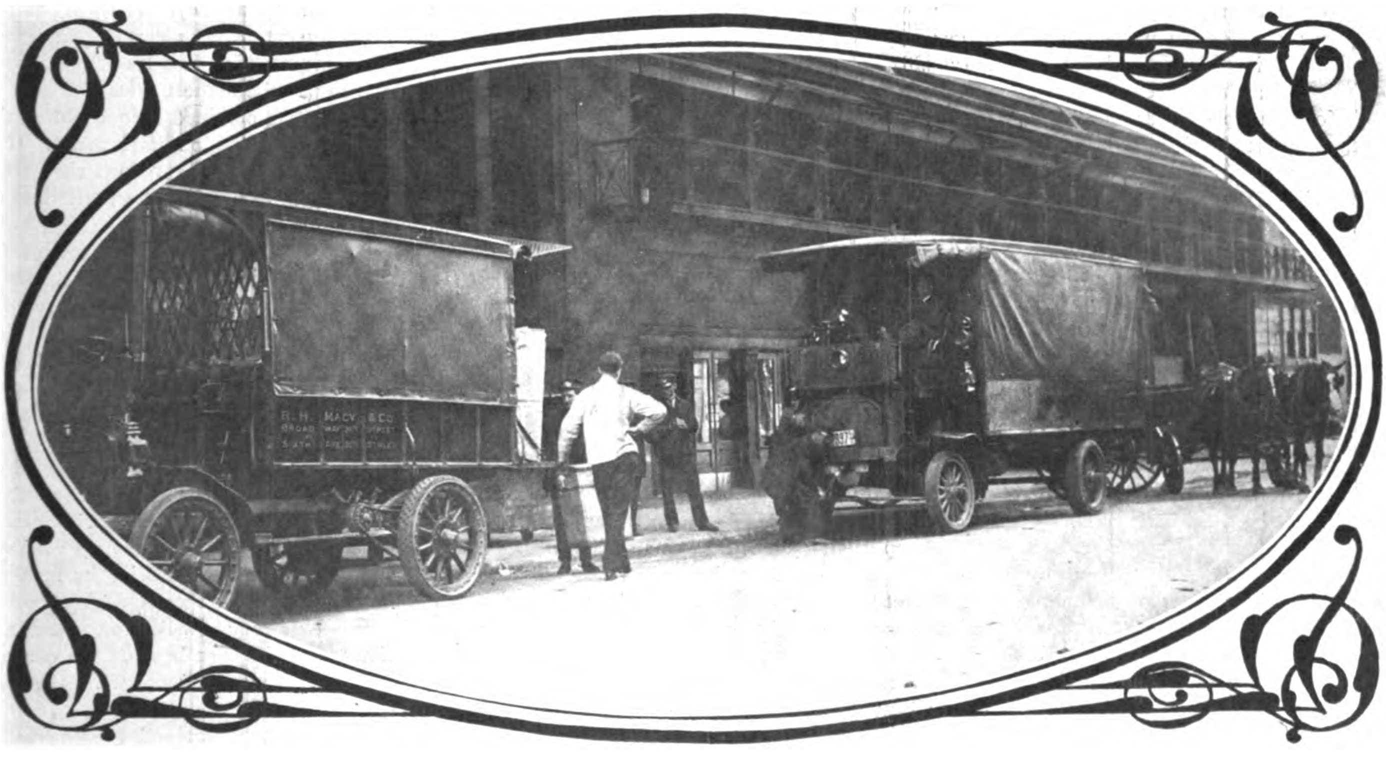
Making Motor Trucks Stay Sold

How Sellers Keep Watch of Cars in Service

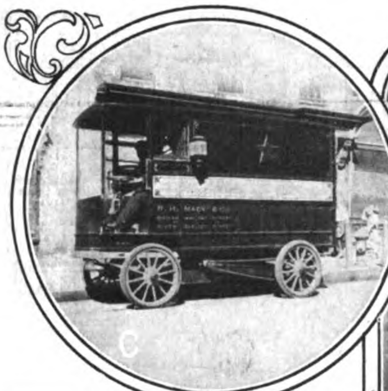
Progress in introducing automobile trucks is vastly helped if the cars in service are kept in a state of efficiency and in order to reach that end nearly all the sellers of trucks keep some kind of official or unofficial supervision of their product in the hands of purchasers. These systems of inspection are extremely varied, but they are all directed toward keeping the cars on the road in shape to perform their duties with economy.

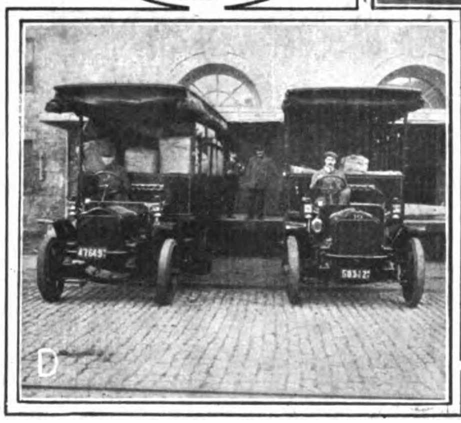
INTRODUCING automobile trucks to the commercial world differs diametrically from the selling of pleasure cars to the general public. There is little in common between the two great branches of marketing cars. On the other hand, the pleasure or utility automobile designed to carry passengers primarily for pleasure, but frequently for business, as in the case of physicians, contractors and salesmen, affords an entirely different selling angle from truck distribution.

The man who buys a car for personal transportation is moved most forcibly by the appearance, price, speed, beauty, silence, grace of performance of the automobile presented, but the buyer of trucks only considers performance as the prime requisite. On the general average it has been demonstrated that it costs approximately 19 cents a mile to operate a passenger automobile and only a comparatively few owners scan the cost figures with searching care. On the other hand, the concern that uses automobile trucks in its business enters and compiles each item of cost with the most scrupulous care. If gasoline consumption shows higher than its normal level; if the tire mileage is less than the purchaser of the car had been led to believe it should be; if the car has to be shopped more frequently and consequently is put out of service longer per month than the owner



A—INSPECTING CARS FOR EXCESSIVE LOAD BEFORE STARTING 14-MILE RUN TO SUBURBAN DEPOT OF BIG RETAIL STORE





C—Small Lansden car used for city deliveries
D—Pair of White trucks transferring freight from warehouse to depot

B—Automobile trucks have widened the scope of retail merchandizing and great care is used in maintaining the cars

thinks it should be, the makers and sellers of the car hear all about it immediately.

In the general movement which is now in progress toward the motorization of all trackless travel, probably one-quarter of the horses that have been displaced by automatic power have fallen before the passenger automobile of private ownership. Fully three-quarters of the jobless horses have resulted from the competition of the truck and even at that the motor truck has provided much work for the equines by extending the scope of business, thus furnishing a use, even if it is only temporary, for thousands of horses that had been originally displaced by the installation of the more economic form of transit.

Service departments for quick, economic and skillful repair and maintenance work have been established pretty generally where there are large numbers of any of the standard makes of automobiles in use and recently the scope of their work has been largely increased by including the trucks within their jurisdiction.

As a general proposition trucks are sold under a guarantee as to materials and workmanship and where a part yields through latent defect and without fault of the operator and owner it is replaced by the selling company without cost.

In the past this provision seemed more important than it does at present, for with the improvement in the methods of manufacture the chance of including some defective part in the assembled car is reduced and the chance of discovering it before it leaves the factory is increased. Then, too, designing has progressed enormously in all directions and the class of materials is better than it was in the early days of truck manufacture.

All these things lend themselves to longer life in the truck and more satisfactory service.

But now after several years of trial and experiment the automobile truck is coming into its own. The manufacturing companies that have alertly followed the trend of events find themselves with more business than they can handle and each day finds many more trucks in service in all lines of commercial work. Buyers are no longer moved to purchase on insufficient grounds. They want to know what the car will transport goods per ton-mile by the year and how much it will cost to keep the car on the road and up to its highest efficiency. The price is important, too, but not the prime essential. For certain classes of work the owner asks himself not: "Can I afford to pay the price?" but "Can I afford not to pay the highest price?"

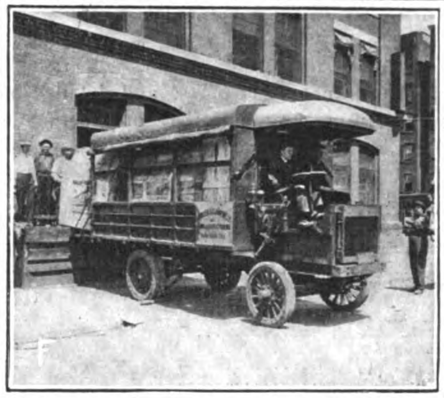
The only reason that the truck has obtained a foothold in the commercial life of the world is founded on its service. If a concern invested $50,000 in trucks and for any reason they were laid up half of the time, the future business in the truck line of that concern would be difficult to get.

The transition from horse-drawn traffic to motorization as far as it has progressed is due to the fact that the trucks do more work than horses at less money cost. Any time that the reverse condition obtains the automobile truck business will decline and die. The single question that confronts all hands identified with the making and using of trucks is service and in order to solve the problem the sellers of trucks keep a fatherly eye upon their product during the life of usefulness.

The system is known by various names in various companies, but its object is the same in all of them, namely, to keep their cars on the road and in condition to earn money for their owners.

When a big concern decides that in order to keep up with the business procession the time has arrived to motorize its transfer and delivery departments, the practice in the past has been to simply buy as few trucks as the salesman will allow them and then to turn over this equipment to the barn boss of the concern with orders to sell off the horses and get busy with the new equipment.

The barn boss may know all about horses and nothing at all with regard to automobiles. This condition is likely to be fiercely accentuated as it applies to his drivers. Putting a mule driver behind the wheel of a $5,000 truck has been quite an ordinary experience and needless to say has proved costly. There is nothing supremely difficult about driving a commercial car. The mechanism is simple, the controls easily mastered and the main principles are not specially involved. Many a horse-driver has made good as an operator of a power truck without special



G—Starting small truck on its daily journey of sixty miles—note the care used in packing the load

E—Randolph truck used for the long hard runs in suburban delivery
F—Heavy duty Alco truck with a load of pianos

schooling, but the percentage of failures in this regard is appalling. The steering presented few difficulties and control was not very puzzling to the average alert driver. The brakes proved bothersome and when it came to the mechanical processes the horse driver was not at home. It took him a long time to learn that lubricating oil in proper quantities was more essential to operation than gasoline and that a burned-out bearing was more serious than a balky team.

Consequently the education of the barn boss and the driver is of great importance when the concern contemplates motorizing its transportation system. The essential character of education in this line has always been recognized by those closely in touch with the industry. The Y. M. C. A. has conducted schools in which drivers and operators of trucks may receive instruction as to their duties, and the New York Fire Department is about to institute a school to train drivers and mechanics for its new power-driven fire apparatus. On July 27 the Packard Company announced that it would maintain a school of instruction for operators of its cars owned by commercial concerns and at the first session of this school there were over twenty students present.

In all these schools the main object to be attained is to emphasize upon the minds of the students the necessity of not doing certain things. Of course the instruction includes affirmatively what should be done ordinarily, but it brings out sharply the necessity for not doing certain things under emergency conditions. These prohibitions include such things as avoiding the attempt to repair a broken crankshaft on the road; or adjusting the magneto; attempting to run without water or oil and a dozen other phases of impossible motoring, at least as far as the inexperienced driver and mechanic are concerned.

The school idea is excellent and in the course of time the business of driving will be on a materially higher plane than it is at present. In fact education is probably the most important thing about operating a truck, because when the operator of a commercial truck knows just what to do, a vast amount of trouble will be saved to the makers of the cars and a vast amount of additional service will be insured to the owners thereof.

The present practice in marketing trucks is to extend the interest of the manufacturers of the cars to their service, as long as they shall remain in service, with the idea of making this period of useful life as long as possible.

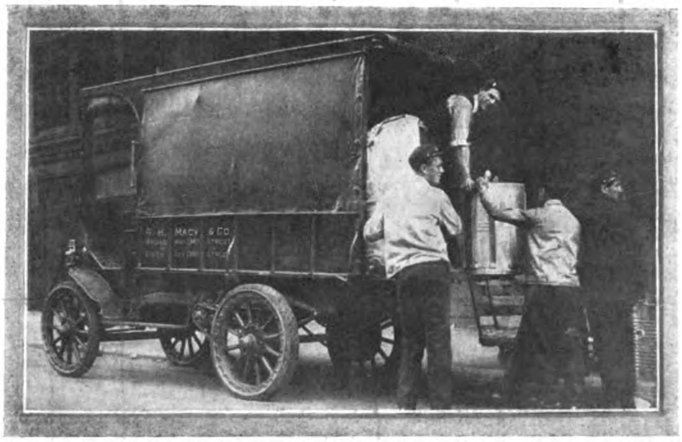
The service departments established in many sections are one of the channels through which the manufacturers extend their interest, but in addition to the actual repair departments the system of inspection referred to above is coming into more general use with each season.

There are a number of these systems in operation, ranging all the way from a kind of street-detective plan by which truck experts examine cars made by their company with or without the knowledge of the drivers and report to the owners of the trucks that certain things are amiss and should be corrected, to an elaborate plan of instruction, personal help, periodic inspection and complete reports on the condition of the cars, such as is the plan kept in operation by the Packard Company, for instance.

One of the typical systems in general use in New York and elsewhere may be described briefly as follows:

When a truck is sold the company selling takes the foreman of the purchasing concern under its wing and instructs him in the mechanical principles of the car and teaches him the details of operation. Then for two days, an expert is detailed to go along with the driver of the car to inform him of its workings. After this the company makes regular inspections of the car and recommends changes, alterations, adjustments and repairs.

In carrying out this plan of comprehensive interest in its cars the following forms are used. The first is a form used in making either regular inspection reports or incidental reports. If one of the cars happens to be seen by an inspector and its condition is not first class, he makes out a report covering the case and as much of it as is necessary is transmitted to the owner with recommendations. Naturally these incidental



H—Unloading a shipment of big metal receptacles from a Randolph car

reports are not so complete and detailed as those which follow regular inspections, but they may be made on the same form, which is as follows:

TRUCK INSPECTION REPORT

.... *Date*....................

Signed..........................

As a cross check on the cars some of the companies urge a careful tabulation of each item of daily expense on each car operated. These tabulations give mileage, material and other items in the daily cards and these totals are transferred to monthly reports from which yearly records are made up. By simple divisions, the wagon mile cost and ton-mile cost may be deduced as applied to total expense and with relation to each of the various factors that go to make up operative costs. These, as have been shown authoritatively in The Automobile, consist of tires, fuel and oil, garage work and supplies and do not take wages of crew and garage rentals into consideration.

The forms are as follows. The first is the daily trucking sheet:

DAILY TRUCKING SHEET

Truck No........... *Driver*................ *Date*...................

Material	Quantity	From	To	Arrived	Left	Miles

The second is the monthly expense statement:

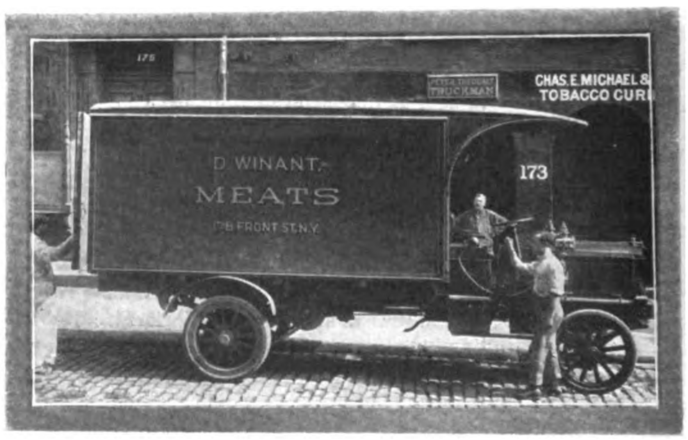
Thus at the end of a period of years the owner knows to the fraction of a mill what it costs him to operate each of his trucks. The daily reports always give warning of coming mechanical troubles and by keeping watch of them serious lay-ups may be avoided and the mileage of the car kept up to its normal without mountainous expense.



I—The factory inspector may be present incognito to note the condition of cars

He can tell at a glance how long the car maintains its highest efficiency and exactly where expense begins to pile up, indicating the need of overhaul and replacements. Also by comparison with reports of other years or months covering the same trucks he can tell whether repairs have proved effectual in checking operative expense along lines that appeared excessive.

Undue quantities of fuel or oil used in operation stand out sharply from the normal or average level and excessive speed has its inexorable effect upon the cost of tires and mechanical upkeep. There is no need of an automatic governor to limit the speed of cars if the daily report sheets are read understandingly. A car that is capable of fifteen miles an hour as a normal speed rate shows the effect of twenty miles an hour in its tire consumption and maintenance bills as certainly as the square of the velocity represents the rate of deterioration of mechanism and increase of tire costs.

The use of the motor truck has become very general in the metropolis and has worked a revolution in the transfer and delivery of goods. To a large extent this good work has resulted from the various systems of inspection on the part of the sellers of the cars. The field has been widened enormously and the merchant who does not take advantage of the improvements offered in transportation is in an uncomfortable position.

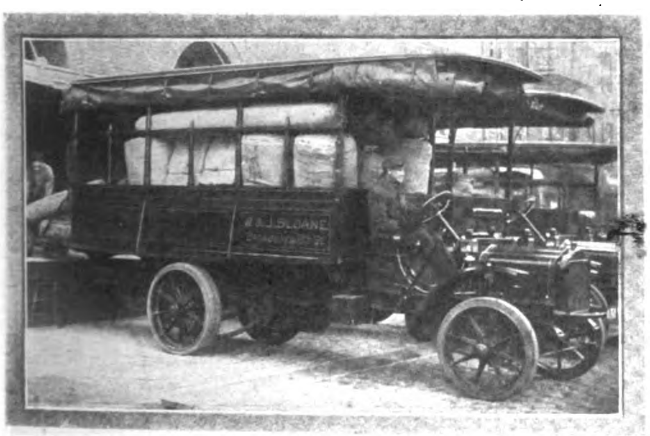
Several of the big retail establishments, such as R. H. Macy & Company, have adopted the automobile in whole or in part in their transfer and delivery systems. At Macy's, for instance, a whole fleet of small electrics is used for urban delivery. These cars are specially available for crowded city work. They take up small storage space and have proved to be satisfactory for this type of service. But the long hauls—the ones that require stiff mileage, speed and carrying capacity, are taken care of by gasoline wagons of various sizes.

When freight is unloaded from ships or railroad cars the loads are carried to the warehouses of such establishments by large sized gasoline cars. Of course there are some of the docks where the gasoline cars are still excluded on account of fanciful ideas about fire dangers, but in the main it may be said that such regulations are being worked out on a sane basis and the strictures will be eliminated in the course of time. The big trucks back up to the dock or freight yard and receive their loads. The cars are generally of three-ton capacity or larger.

The haul to the warehouses requires less time and the loads carried are proportionately larger than they could be with horse-drawn vehicles. Consequently there is an emphatic saving in this stage of the operation.

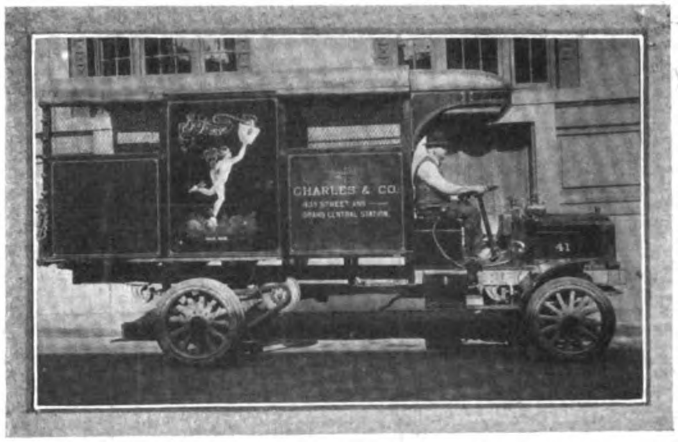
The effect quick transit has had upon retail business is strongly illustrated in the greater radius within which deliveries are now made without cost to the customer in comparison with conditions a few years ago.

For instance a big retail store will have one or more distributing depots located far beyond what were formerly the limits of the free district. In order to take care of this important phase of business the concerns load up big gasoline cars of three-tons capacity or more and make periodic trips from the main warehouses to the supply depots. In one case that was noted by a representative of THE AUTOMOBILE the supply depot was located fourteen miles from the warehouse and each evening the trucks are loaded and sent out with goods destined for delivery on the following day. The cars make the round trip of twenty-eight miles in three hours, transporting three tons of merchandise. Three trips a day could be made with a single truck and the labor represented would be the same as if eighteen horses drawing nine one-ton loads and taking the time of nine drivers had been used.



J—A special point has been made by automobile truck sellers of the education of the users—note the care in loading this White

Twenty-eight miles in a day would be a big labor for a team and certainly the horses do not live that could make two such trips a day under load.



K—Packard trucks like this are constantly under careful scrutiny to see that they are kept at highest efficiency

At the depots the goods are unloaded and sorted for delivery throughout a wide territory and an appreciable amount of such delivery work is done with horse-drawn vehicles.

But another very important portion of delivery work is done by the medium-sized gasoline car. It is pioneer work and requires sturdiness of construction, speed and stability. This is the suburban delivery system. Light, bulky freight such as furniture is handled to a nicety in this way and small parcels, heavy and valuable freight also seems specially adaptable to this form of transportation. Forty, fifty, sixty miles a day are not unusual mileages for the automobiles assigned to this branch of the service. There is nothing easy about it and from the fact that there must be a long barren haul of the full load from the warehouse to the inside delivery limits and another long haul after deliveries have been made, make this kind of service peculiarly trying from the viewpoint of expense. Of course it would be economically impossible with horses as motive power and really represents the modern expansion of commercialism in its simplest form. Natural development of business might account for all the other elements of trade, but in the absence of branch stores, which have not proved perfectly satisfactory as a solution to the problem, the gasoline suburban delivery service has been the means through which the end has been accomplished.

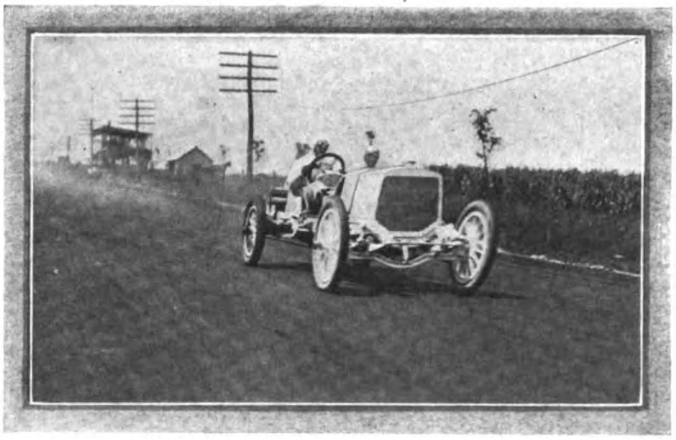
Take a typical case to illustrate how inspection helps the owner to maintain his cars on the road: If an overloaded truck being driven at excessive speed is seen by an inspector, the facts are laid before the owner perhaps a month before the effects of such overload and excess of speed would make themselves apparent in putting the truck out of service.

If the motor acts abnormally or if any one of a dozen different faults are noted in the mechanism or if due care is not apparent in the operation of the truck, the facts properly reported may lead to saving a big repair bill and in keeping the truck on the road without a break for years.

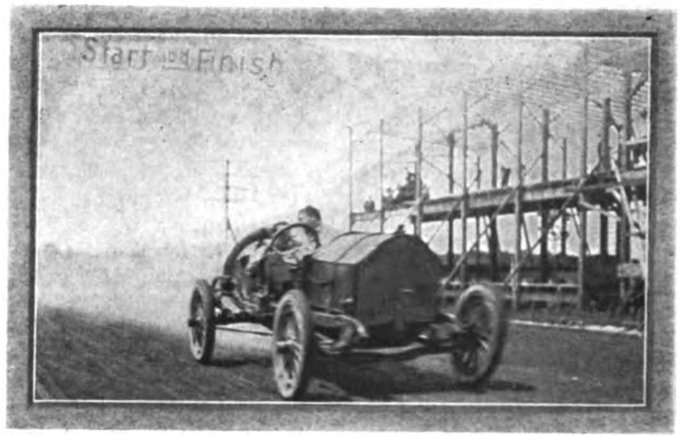
Progress is to be noted in every branch of industry, but nowhere is it more apparent than in the commercial automobile. And now naturally follows the careful inspection of the cars so that this progress may be accentuated. So far the means of accomplishing this end have been vague, general and unorganized, but the trend of the times is all one way and development of the systems of inspection will undoubtedly form an important step in the perfection of the motor truck.

As has been shown, some of the companies have grasped the situation strongly and understandingly. The main object of the truck industry is not now to sell cars, but to sell cars that give service and consequently make a ready market for more cars as the exigencies of trade prepare a place for them to work.

The proof of the pudding lies in the eating thereof, and with the institution of adequate factory inspection after the cars have passed into the hands of purchasers, the universal use of the automobile truck does not seem so very far away.



Lozier, No. 12, Mulford driver, in a fast try-out



Cole, No. 25, with Jenkins at the wheel, going at a 65-mile clip

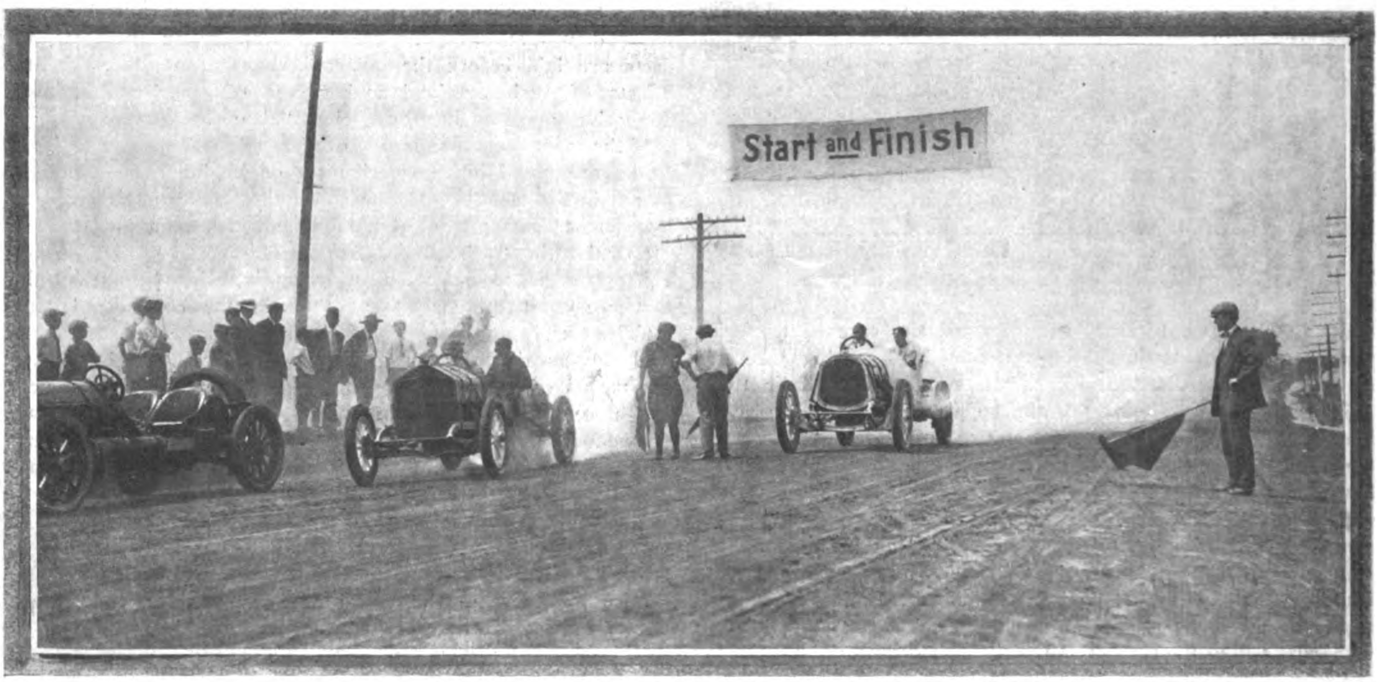
All Eyes Turn Toward Elgin Course

National Stock Car Championships to Be Run

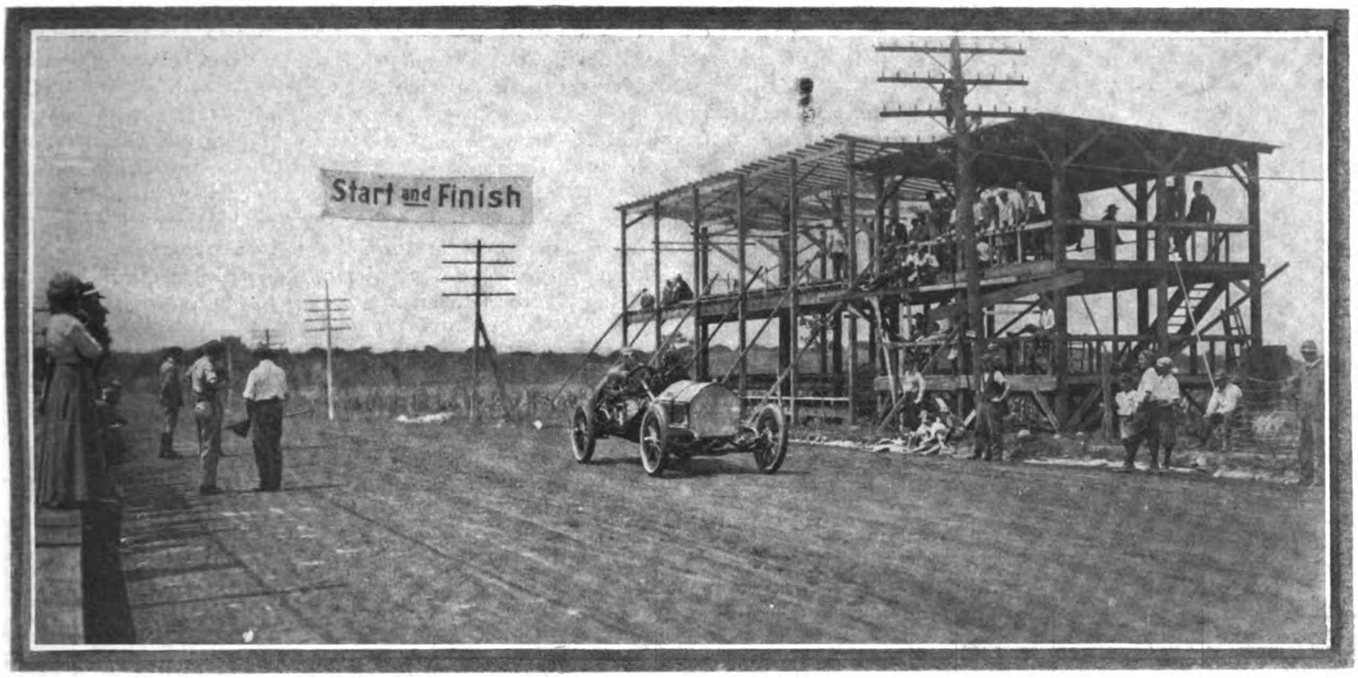
With an entry list of thirty-five, divided among the four big stock car races of the year which will be held over the improved course of Elgin, Ill., on Friday and Saturday, the indications point to fast time and sturdy performance in all the classes. Already one of the entered cars has turned the course at better than a 70-mile-an-hour-clip. Ireland, driver of a Staver, met death on Monday during practice.

CHICAGO, Aug. 22—With a free field, as far as competition is concerned, the Elgin National Stock Chassis races, scheduled for Friday and Saturday, give promise of again proving to be the most important events in Western motordom. There will be four races, as was the case last year.

The cars of the 301-450 class will run for the Illinois Cup at 202 miles on Friday, along with the other two divisions. The 231-300 class for the Kane County Cup at 169 miles, and the 161-230 class for the Aurora Cup at 135 miles. On Saturday the cars of under 600 cubic inches piston displacement will run for the famous Elgin National Trophy, a perpetual challenge cup, which last year was won by the Lozier (Mulford). The big race will



Scene at the tape when the majority of the contestants came out on the course for a series of practice speed trials



Showing the excellent condition of the track in front of the uncompleted press and timers' stands

be at 305 miles and will be the only event on Saturday. The closing of the entries Sunday night found thirty-five names in the box, one more than last year, with twelve in the Elgin National, four in the Illinois, sixteen in the Kane County, and only three in the Aurora.

These are a most representative lot, including fifteen makes—Lozier, Alco, National, Simplex, Pope-Hartford, Mercer, Velie, Staver-Chicago, Cole, Corbin, Colby, Cino, Falcar, Ford and Abbott-Detroit.

All of these are almost certain to go to the post with the exception of the Falcars.

All the turns have been widened, and the only possible criticism is found in a few thank-ye-ma'ams in the back stretch, which are no trouble when traveling at high speed. The home stretch almost is like a boulevard, especially that section between Hornbeek's Turn to Britten's Hill, just west of the grandstand, a one-mile strip which is 54 feet in width, extending from fence to fence and seemingly capable of 90 miles an hour.

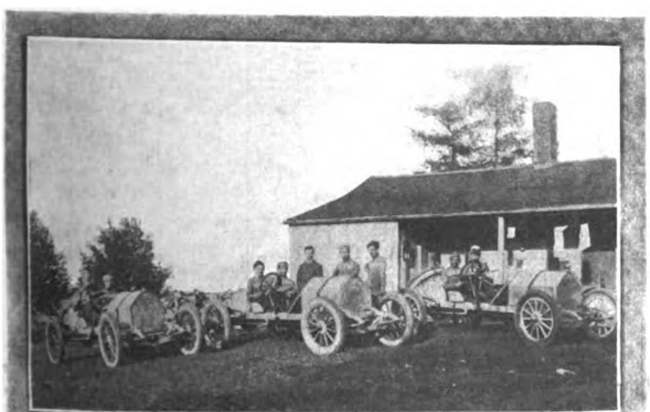
Udina Turn now is 80 feet wide. The races will start at 11 o'clock each day, instead of at 10, as was the case last year, and the course will not be closed until 10.40 A. M., which ought to increase the attendance, for the main difficulty in the past has been to get the spectators seated in time.

Most of them dislike the idea of having to go out to Elgin the night before, and the idea of getting a start from Chicago at 5 A. M. is displeasing to the majority. Now, with all the transportation arrangements that have been made, it will be possible to leave this city as late as 8.30 o'clock and still get up to the course in time.

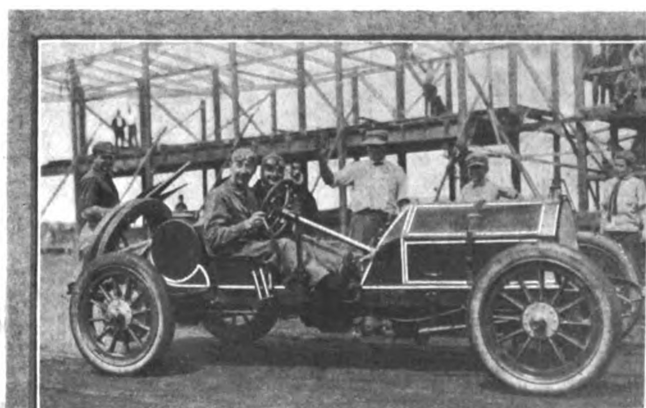
The military arrangements are complete, and for the third time Chicago will have use of the troops. At Crown Point two years ago, the Chicago Automobile Club accomplished the seeming impossibility of taking an Illinois regiment, the First, into Indiana. Last year the Chicago Motor Club had the Eighth Illinois at Elgin, while this year 200 men from the Third Illinois will guard the course the first day, while on the second day the First Illinois Cavalry, a Chicago troop, will be on the job, dismounted, of course.

Practice for the races started last Friday according to schedule. Grant, in the Alco, made the circuit in 8:02, at the rate of a little better than 60 miles an hour, and Aitken, in the National, swung around in 8:11.

On Saturday Mulford was clocked in 7:13, better than 70 miles an hour. His second lap was only 2 seconds slower. Aitken in the National was credited with 7:23 and 7:22; Meyers' best time was 7:36; Zengel, another National driver, did 7:35



Staver team in front of its quarters—Nikrent, 16; Robillard, 25; Monckmeier, 27



Mercer, No. 9, with Hughie Hughes in the driver's seat and 7:56; Herr, the fourth man on the blue team, did 7:50 and 7:55; Hartman in the Alco turned 7:55 and 7:58, Grant did 7:42 and 7:47, while Hughes showed the pace of the Mercer by clocking 7:47 and 7:50.

On Monday Grant opened the throttle a bit for 7:43, while Wishart showed a bit of Simplex speed for the first time, being blocked in 7:41. His team mate, De Palma, was contented with a slower lap, his best time being 7:52; Aitken was recorded in 7:48, Hughes in 7:45, and Hartman in 7:43.

The following assignments of numbers have been made:

Elgin National: 1, Alco, Grant; 2, National, Zengel; 3, Pope-Hartford, Buck; 4, Simplex, Wishart; 5, Alco, Lee; 6, National, Aitken; 7, Alco, Hartman; 8, Cino, Raimey; 9, Mercer, Hughes; 10, Cino, Burt; 11, Simplex, De Palma; 12, Lozier, Mulford.

Illinois Cup: 1, National, Herr; 2, Velie, Jeffkins; 3, National, Merz; 4, Velie, Stickney.

Kane County Cup: 11, Cino, Burt; 12, Mercer, Barnes; 14, Corbin, Maisonville; 15, Mercer, Hughes; 16, Staver-Chicago, Nikrent; 17, Falcar, ——; 18, Colby, Ogren; 19, Falcar, ——; 20, Colby, Pearce; 21, Cole, Morris; 22, Colby, Armstrong; 23, Falcar, ——; 24, Cole, Jenkins; 25, Staver-Chicago, Robillard; 26, Cino, Raimey; 27, Staver-Chicago, Monckmeier.

Aurora Cup: 31, Abbott-Detroit, Robbins; 32, Ford, Kulick; 33, Abbott-Detroit, Roberts.

Problems of Steering Mechanism

Analysis of Factors Governing Correct Design

In this article, reprinted from the Motor Trader, A. Cattaneo discusses the problems which affect the steering mechanism of the automobile, with some notes especially referring to the correct placing of the tie-bar and to the power lost by want of parallel wheel tracking.

FOR a theoretically correct steering it is imperative that the axes through the wheel spindles should radiate from a point situated on the back axle, as shown at D, in Fig. 1.

FIRST ESSENTIAL FOR A PIVOT STEERING—Fig. 1 shows this when the front wheels are moved from position I into position II. It has, however, been found that the practical fulfilment of this condition would require a prohibitive number of links or other complications, and a theoretically correct steering is, therefore, never met with.

The designer of the steering arrangement has, consequently, the following problem to solve. To connect in the simplest manner the front wheels in such a way as to obtain the greatest approach to the theoretical condition. Suffice it here to state that the quadrilateral style, either as an interior or exterior quadrilateral, is now universally used. The simplicity of this arrangement is one of its strongest points, and when carefully designed it may be made to fulfil all that is required of it as a substitute for unpractical devices. Unfortunately, however, its arrangement on many modern self-propelled vehicles points to the fact that the necessity for accuracy in laying out the quadrilateral is not fully appreciated, nor is its general design often sufficiently understood and considered.

ACCURACY IN TRACKING—In consequence of this inaccuracy the front wheels do not automatically adjust their angularity when negotiating a bend, but instead are compelled to slide over the road, with a corresponding detrimental effect on the life of the tires. There being more obvious factors responsible for the wear of the tires, the amount really attributable to the inaccuracy of the steering is liable to be underrated, if not overlooked altogether; and this, no doubt, accounts for the fact that hardly any improvement is attempted in the design of the steering connections.

On checking the accuracy of the steering of many cars it will be found that, by a very slight alteration of the quadrilateral, in almost every instance the degree of accuracy could be improved, and the life of the tires and the comfort in steering correspondingly increased.

HOW THE QUADRILATERAL IS FOUND—Fig. 1 shows that for an angle a of one of the front wheels, their corresponding axes intersect each other at a point D on the prolongation of the back axle. This only holds true for theoretically correct steering; practically such points as D will be located on a curve, enclosing with the back axle a surface which can be taken as a criterion for the accuracy of the steering, and of the extent to which this will tax the life of the front tires. Unfortunately, this method is of no practical value; the process of finding the axes of the wheels corresponding to a certain angle being a lengthy one; moreover, for a certain range of lock, the intersection of these axes would lie quite outside the drawing board, unless a very small scale be employed, and the accuracy of the result correspondingly impaired.

A little mathematical consideration will show how to evade this difficulty, besides giving a practical mean for comparing different results with each other and discussing them. Hence, referring to Fig. 1, let b equal the wheelbase, and 2d equal the fixed distance between the pivots A and B. Suppose, however, that the front wheels are moved from position I into position II, then carry the corresponding angle a of wheel A on the right-hand side of A; obtain, as shown, the point E on B D, and draw E G perpendicular to A B. Then the triangle A G E is similar to triangle A C D. By making the center F of the front axle the origin of a system of co-ordinates, it is:

$$y : b = (d - x) : AC \qquad AC = b\,(d - x) : y$$

triangle B G E is similar to triangle B C D; therefore:

$$y : b = (d + x) : (2d + AC), \text{ or}$$

$$y : b = (d + x) : [2d + b\,(d - x) : y].$$

After making the necessary operations we find

$$2\,dy = 2\,bx, \text{ or } y = (b : d)\,x,$$

which is the equation of a straight line L L going through the center F of the front axle, and making with it an angle e; so that

$$\tan e = b : d.$$

It is obvious that this relation holds true for any value of the angles a and c; therefore, the line L L contains all the points obtained in the same manner as point E. This, again, is only theoretically correct; practically such points as E lie on a curve, including with L L a surface which can again be taken as a criterion of the accuracy of the arrangement of the quadrilateral.

AN ERROR IN STANDARDIZATION—The diagram shows also in an obvious manner that the very common practice of using a standard steering arrangement for different types of car, although very convenient for the manufacturer, should be departed from on account of the increased inaccuracy involved.

For illustration of this it is sufficient to refer to Fig. 2. If curve 1 corresponds to the best results obtainable with a certain quadrilateral on a 11-ft. wheelbase car, by reducing this length to 9 ft. the angle e is also correspondingly reduced; that is, line L L moves farther away from the curve which, of course, by retaining the old quadrilateral remains the same, and the increased surface lying between the new line L L and the curve shows to which extent the accuracy of the steering has been reduced.

Again, suppose the front axle and the wheelbase to be given. The first one only needs to be shown in the drawing. Through its center draw a line L L under an angle e, so that

$$\tan e = b : d.$$

Assume a certain quadrilateral, *e. g.*, that marked 1; move one of the wheels (for sake of argument, A) at different angles to the left, one of these being angle a; carry this angle inside by drawing the line A Q; find the position S of the lever r, and by means of the tie rod l determine the corresponding angle c of wheel B. Produce the axis of this new position of wheel B until it intersects the line A Q at a point P. This process applied to a few different angles will supply as many points; by joining which a curve—such as the one marked 1—is obtained, approaching more or less to line L L, according to the accuracy obtainable with the quadrilateral in question. It is, of course, only necessary to obtain one branch of the curve; for instance, the one lying inside the front axle, and corresponding to a movement to the left, as for an equal lock to the right the curve is symmetrical to both the front axle and line L L.

A PRACTICAL DEDUCTION—The advantages of this method are too obvious to require comment. The arrangement can be sketched out almost to full size, and, therefore, very accurately. By slightly varying either the length or the angularity of the steering levers r, a quadrilateral can easily be found giving the greatest accuracy obtainable.

Again, by comparing curve 4 with curve 1, it will be noticed at once that quadrilateral 4 gives greater accuracy than quadrilateral 1; the latter being obtained in the usual manner by setting the lever arms r at such an angle that they intersect on the center of the back axle. This method of laying out the quadrilateral should, therefore, be discarded, and both steering arms be made to intersect in front of the back axle and at a distance from it about equal to the fixed distance between the pivots of the steering wheels.

The correct position of the point of intersection cannot be given, as the ratio of wheelbase to length of front axle is not constant; but by assuming different positions for the point of intersection of the steering levers, and by plotting the corresponding curves, it will be an easy task to see which arrangement gives the best results. The diagram will also throw light on the important question whether an interior or an exterior quadrilateral should be adopted. The latter arrangement is gaining favor among the leading makers, and, were its advantages fully understood, one would wonder why the interior quadrilateral is still adhered to.

Correct Position of Tie-Bar—By comparing curve 1 with curve 2 (Fig. 2) it will be seen that with the same length and angularity of the steering levers the "in-front" disposition gives not only mechanical advantages, but also a markedly greater accuracy, due to the increased length of the tie-rod. It can easily be proved that for a given interior quadrilateral an exterior one can be found to realize better the theoretical condition for correct steering. There are other points that speak in favor of the "in-front" arrangement; so many, in fact, as to totally outweigh whatever reason may be urged in favor of the rear placing.

The advantage of having the tie-rod under tension is not a trivial one. The strength of the material is better made use of; but the rod should not on this account be reduced in weight, as the peculiar conditions under which it transmits power from the steering wheel require—in the case of an exterior quadrilateral—a larger section for the tie-bar than is permissible with the interior one. This is readily accounted for by bearing in mind that the coupling bar is to be considered as a connecting rod in which buckling stresses are set up, and, therefore, the strength of its section diminishes inversely with the square of its length. But even in this respect the "in-front" position scores. It permits a strong, straight bar to be used, whereas with the interior quadrilateral the middle part of the tie-rod, which is, unfortunately, also the dangerous section, is very often to be found bent, or cranked, to clear the engine basechamber, or some other part, with an obvious detrimental effect on the strength of the arrangement.

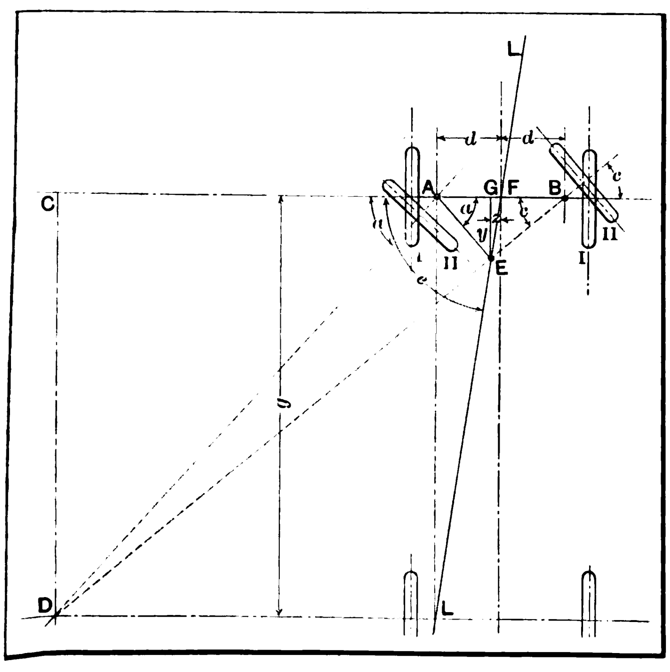

Fig. 1—Illustrating the theory of a correct steering design

The "in-front" position of the tie-bar facilitates, to a great extent, the erecting of the steering connections, and is surely the best from the point of view of upkeep, for it allows the joints to be easily inspected and their lubrication to be properly attended to, and also permits the tie-rod itself to be easily removed and repaired.

By the opposed or rear position of the tie-rod and steering arms it is claimed both are protected, so that the steering would not be disabled in case of a collision. This sounds quite reasonable, and it is as a matter of fact the only good point in connection with the interior quadrilateral.

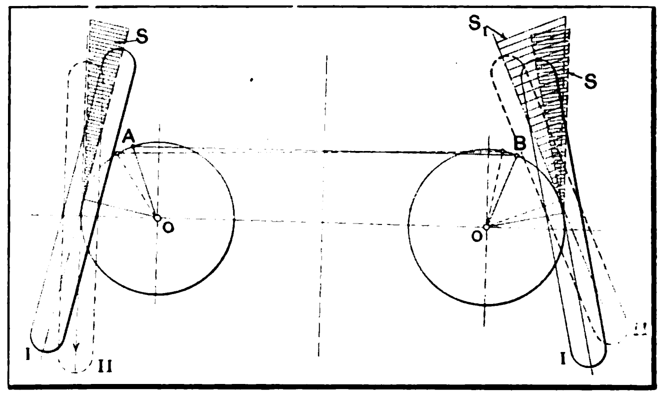

Fig. 4—Illustrating compromise setting for a racing car

Here it may be opportunely remarked that, by placing the tie-rod in front, it can also be moved farther away from the ground than is the case with the interior arrangement, and any accident that would then affect the tie-bar would most probably also injure some other part, if not disable the car.

It is also claimed for the rear placing of the tie-rod that the absence of links and levers enhances the good appearance of a car, when viewed from the front. It is undoubtedly better in many instances, whether for esthetic or other reasons, if the front axle be made to screen some of the fancy shapes of the crooked tie-rod one sees, but, on the other hand, the critic will fail to see how the elegant and graceful lines of a modern chassis could be spoiled by a neat and straight rod placed symmetrically both to the front axle and frame.

Finally, it is also urged against the exterior quadrilateral that, by its adoption, the ends of the steering levers may come dangerously near the spokes of the wheels. This point should not be overlooked by the designer, and before definitely adopting a quadrilateral he should make himself sure that it gives the greatest accuracy with a reasonable amount of clearance between the spokes and the ends of the steering arms, for each angle of the front wheels, within the range of lock.

Angularity in Steering Wheels Setting—For another species of practice retained by a few designers a plausible explanation still obtains. I refer to the practice of setting the steering wheels out of parallel, so that they converge at a point in front and on the axis of the car. The angularity is very small, the angle included by both wheels being no more than from five to seven degrees: and this undoubtedly accounts for this practice remaining often unnoticed or undetected.

The modern motor vehicle is admittedly designed on compromises. Some of these nearly give ideal conditions, while others would barely stand a close investigation. Regarded from this standpoint, it will serve to examine the behavior of both systems of setting the steering wheels, and with a view to ascertain whether it would not be possible to arrive at a compromise which would embrace the advantages of both systems, and reduce, if not eliminate, their respective drawbacks.

Parallel vs. Angular Setting Analyzed—Referring to Fig. 3, both wheels, which are parallel, are shown with the quadrilateral O A B O in the neutral position I, while the car itself is supposed to be traveling in the direction of the arrow, overcoming a certain resistance R acting in the axis of the vehicle and equally distributed between the two wheels. These two forces, however slight they may be, being transmitted through spindle and lever to the tie-rod, and the two components lying in its direction, are obviously neutralized.

Let us now suppose that the wheels be moved from position I into position II, and the same resistance R be acting again in the axis of the vehicle—both these forces R are supposed equal, the angles to which the wheels are locked being taken very small; they, therefore, need not be specially inquired into, and can be represented by the length R.

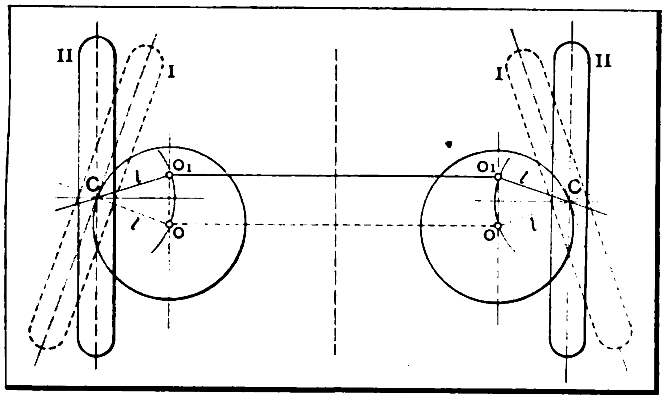

Fig. 5—Illustrating a theoretically correct setting

It is easy to resolve this force into two components, one of them in the direction of the wheel axle, and taken up by the steering pivot, and the other at right angles to the first. If, for the sake of simplicity, the wheels are supposed not to be splayed, and, moreover, the distance between center of wheel and center of pivot be equal, the length of steering arm (the component of R at right angles to the spindle) will be found again at the end of the steering arm and perpendicular to it. Here this component is resolved into two others; one in the direction of the steering arm, and taken up by the pivot, the other lying in the direction of the tie bar, tending to pull this over the left. Let this component be called P.

For the steering to be in a condition of equilibrium, it is obviously imperative that this force P be destroyed by another equal force acting also on the tie-bar, but in the opposite direction. By applying the procedure just described to the other wheel, whose position is determined through the assumed quadrilateral, it will be found that not only is the corresponding component force P1, in the tie rod, different from P, but, and this is the serious point, it is also to a markedly smaller amount. In this connection it should be pointed out that for the purpose of showing better this peculiar behavior, the quadrilateral has an exaggerated angularity, and the angles of lock shown could only be obtained with a considerable movement of the steering wheel. Nevertheless, the diagram shows that the arrangement is not in a state of stable equilibrium.

Why Wheel Wobbling Occurs—With an accurate quadrilateral, smaller lock and sufficient splay of the wheels, the difference P, P1, will certainly be reduced, but without it being possible to entirely eliminate it. As has already been pointed out, the peculiarity lies in the fact that, unfortunately, P is always greater than P1; or, in other words, when the wheels are moved a certain angle a tendency is also created to automatically increase the initial lock. This was very apparent with the earlier cars.

The advent of irreversible steering gear was a step in the right direction, but did not affect this tendency by which the wobbling of the wheels, and not a few so-called mysterious accidents, can easily be explained. If, when riding over rough roads, or in meeting an obstacle, the impact be strong enough to cause the particular wheel to assume a certain angle (the play at the joints and the springs interposed in the steering connection will always allow a wheel to give a bit), the resistance then creates a tendency to follow up the lock, and this will really follow until the buffer spring at the ball joint of the steering arm is fully compressed. Hence, if then, for some reason or other, the resistance diminishes, the fully compressed spring "shoots" both front wheels back in the neutral position, and, perhaps, over it, and the process is ready to begin again. If such resistance be not reduced the driver will be called upon to rectify the angularity of the wheels.

Defective Tracking Causes Large Power Loss.

In measuring the tractive efficiency of a motor car no account is taken of any formula of the power absorbed by the front wheels, these being taken as running parallel, i.e., tracking correctly. If, however, this condition be not fulfilled, there will be a large additional loss; the efficiency might be as high as could be desired, and yet, under otherwise the same conditions, the behavior of the car on the road would make but a poor show as compared to the one of another car of lower efficiency and faultless setting of the front wheels. In the case of a 40 brake-horsepower car without having met with an accident necessitating the fitting of new front wheels, it was found that the highest speed obtainable had fallen from 50 to 42 miles an hour. The engine had been untouched, and the transmission turned as smoothly as before.

When, however, the front wheels were tested for parallelism they were found to be "out" by 4 degrees. At first, so apparently small an error was considered too trivial to be reckoned a possible cause, but on plotting the deviation graphically it was found that at 2 degrees from being parallel 3 horsepower was absorbed, increased to 6 horsepower at 4 degrees and 9 horsepower at 6 degrees on each plotting at 50 miles an hour with a pro rata scale for the lower speeds. The moral, therefore, is obvious.

A Racing Car Compromise—A solution of the angularity dif-

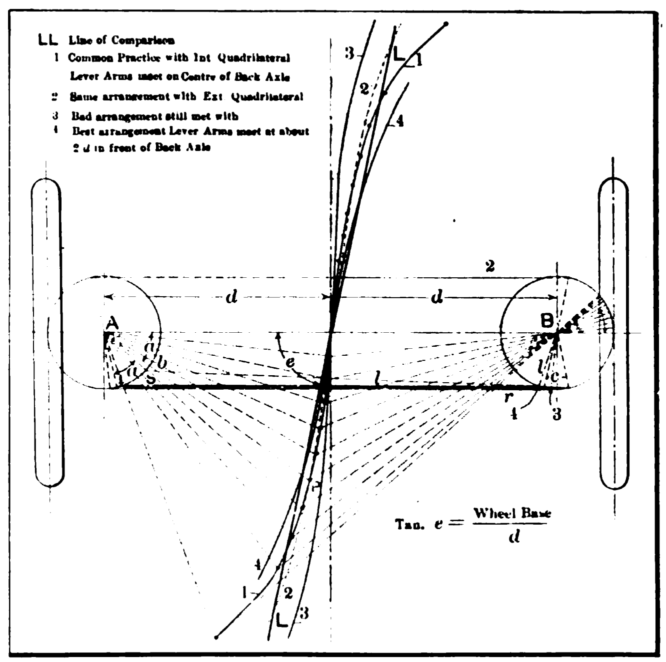

Fig. 2—Comparative graphs of types of steering design

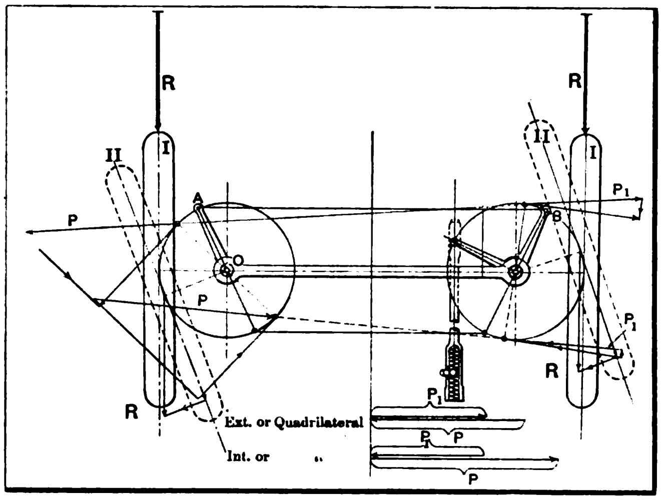

Fig. 3—Illustrating parallel vs. angular wheel setting

ficulty as it concerns racing cars is shown in Fig. 4. It will readily be seen that, owing to the wheels being not parallel their motion is of a mixed rolling and sliding character. When driving straight along with the wheels in the neutral position, the amount of work corresponding to the sliding motion is obviously equal for both wheels, being mainly dependent upon the angle they enclose. It can, therefore, be assumed proportional to the surfaces S, S. If the wheels be moved from position I into position II, the work S of the "leading wheel" is reduced from S to zero, while for the other it increases from S to S1, that is to say, for a certain lock the off-side wheel has to overcome a much greater resistance; it opposes, therefore, to an increase of the angularity, and tends to bring back the wheels to their neutral position. This steering is positively stable; a shock which would produce a certain lock at one wheel has also to overcome the increased work of friction of the other wheel; that is, the force of impact will never produce any considerable angle at one wheel, and even if that could happen the steering would at once right itself. A car, when going at a good speed, would always keep its direction, even in case the steering arrangement should become valueless.

A Drawback and a Deduction.—As it has been pointed out before, this setting has the great drawback of taxing the life of the tires to an almost alarming extent, on account of the sliding motion to which the wheels are subjected. Moreover, their angle being small, unless great care is taken in erecting, the angularity will probably not result the same for both wheels, which means increased wear of tires and unstability of steering. Some makers use for the setting a kind of jig with correspondingly more accurate results. It would seem, therefore, that the correct setting of the steering wheels should combine the true rolling motion of the parallel system with the stability of the converging arrangement.

An Effective Compromise—Referring to Fig. 5, it will be seen that this condition may be easily attained. Let C O O C represent a front axle corresponding to the neutral position I of the wheels; these latter converging at a point in front of the car. If the distance C C and the length of the steering lever are constant, and both wheels are made to turn about the points C C as their respective centers, the points O will have to move to O1, and a new position C O1 O1 C for the front axle is obtained. This not only allows for the wheels to run parallel, but has also the stability of the converging arrangement.

Recently some makers, appreciating the advantages of the setting shown in Fig. 5, have accordingly modified the front axle of their new cars by adopting the form shown in Fig. 6. It is easy to prove graphically that this setting of the steering wheels is as stable as that shown in Fig. 4. To carry out this, the same procedure may be applied as was done for the arrangement shown in Fig. 3.

It will be found that for no matter at whatever lock to the left, the force P1 is always greater than P; that is to say, there is a tendency for the wheels to return in their neutral position whenever, for some reason or other, they have deviated from it. The common practice of splaying the wheels reduces the strains in the pivot, may even eliminate them altogether under certain circumstances; but as the length of the steering levers is usually greater than the distance between the center of the wheel and the pivot, the stresses in the tie rod are almost always present.

Another Factor in Wheel Wobbling—The circumstance that wobbling is apparent to a greater or lesser degree on different cars points conclusively to the fact that, while unable to entirely avoid the causes of the unsightly occurrence, some careful designers have, however, succeeded in reducing to a minimum the unsteadiness of the front wheels, improving thereby not only the appearance and the running of the vehicle, but also the wear and life of the tires and steering connections. The remedy is so simple and obvious that no doubt it would be generally adopted, were the designers of motor cars only to give this point the proper amount of thought and consideration, bearing in mind that not only ought the steering to be made a mechanical and accurate job, but also that its connections should be so contrived as to minimize whatever disturbance may arise through the floating suspension of the front axle. The neglect on the part of designers to take these disturbances into consideration when laying out a steering arrangement is certainly a fruitful cause of the wobbling of the front wheels, as will be clearly shown by even a superficial examination of Fig. 7. This diagram represents the generally adopted method of front axle suspension, by which the front end of the spring is hinged at a fixed pivot on the frame, while the rear end is suitably shackled, so as to permit the elongation of the spring to take place only in a rearward direction. If, now, the riding over an obstacle causes the spring to be deflected from form I, say, into form II, the front axle will no more remain in the same vertical plane, but will obviously follow the movement of the spring to which it is rigidly attached.

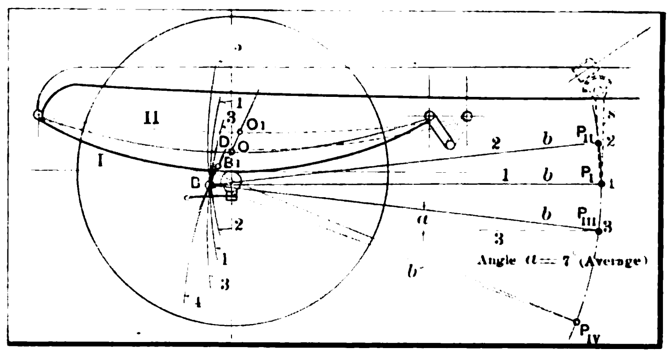

Fig. 7—Illustrating imperfect design as a cause of wobbling steering wheels

The path of this movement will be a certain curve, dependent upon the vertical displacement of the wheel, and upon the corresponding deflection, that is, elongation, of the spring. Let O be the center of the spring when in the neutral position, I, and O1 that corresponding to position II; then O and O1 are obviously two points of the curve referred to. For the sake of simplicity suppose these points O and O1 to be connected through a straight line, which, instead of the theoretical curve, is now taken to represent the path along which the centre O of the spring moves, when this latter has been deflected to a corresponding amount.

The front axle evidently partakes of the same movement; and so would the spherical knob B—supposing the rod b to be removed—displacing itself along a straight line BD, parallel to OO1. If the steering arrangement marked I is considered, it will be readily seen that on account of the immobility of point P1 the only possible movement of the ball B is along a circle 1, struck from P1, with b as radius, and passing through the centre of B; in other words, the steering knob B alters its relative position to the front axle to an amount represented by the surface enclosed between the arc of circle 1 and line BD. It is obvious that this displacement causes the wheel to be moved sideways to an amount corresponding to the shaded surface enclosed by the theoretical and actual parts of ball B. When the spring returns to its neutral position the reverse proceeding takes place, and the wheels are automatically set straight again.

Effect of Front Spring Deflection on the Steering Gear—It is easily conceivable that if a vehicle is too lightly sprung the riding over an ordinary road will cause the springs to be in an almost perpetual state of oscillation, resulting, as has been shown, in wobbling of the front wheels.

The buffer springs, interposed at the point P1 between the steering arm a and the connecting bar b, may under circumstances permit the latter to "go back" a small amount, with the consequence that the ball joint B will no more describe the circle 1, but moves instead along a new curve, lying between circle 1 and line BD, and approaching more or less to this last-named, according to the stiffness of the cushioning springs referred to. The purpose these buffers are intended to serve requires them to be fairly strong; it seems, therefore, that the best solution of the difficulty would be to find such a position for the point P1 that the circle struck from it as centre, and with b as radius, would practically coincide with the theoretical line BD. It is fairly obvious that this condition will be fulfilled if the point P1 lies on a line drawn normally to the centre of the path, as shown for point P4.

In this connection it is interesting to point out that some makers, by adopting for the connecting bar the disposition marked 2 (Fig. 8) not only seem to forget the requirements of a correct steering, but also to be positively striving to increase an unfortunately unavoidable inaccuracy. As it can be readily seen in the diagram, the higher point P II is in relation to B the greater will be the discrepancy between the theoretical and actual paths of the knob B, and the greater, therefore, the tendency to wobble in the front wheels. The point P4, obtained in the manner shown

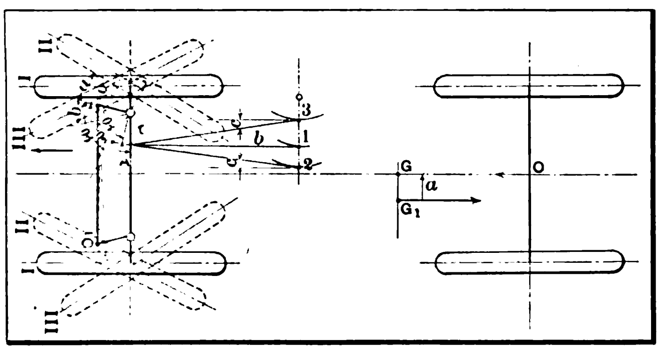

Fig. 8—Illustrating the effect of a faulty distribution of weight

in Fig. 7, is the only position for the lower end of the steering arm a, for which the discrepancy referred to can be neglected.

To avoid wobbling it is, therefore, imperative that point P III should approach P IV, as close as practically possible, a condition which can be translated into practice only by placing the connecting bar at an angle, raising towards the front of the vehicle, as it is shown for the arrangement marked 3. The increased length of the steering arm a that would result from this disposition can easily be obviated by placing the ball joint B above the front axle. The angle included by the connecting bar b and the horizontal axis varies on different cars, but an average value of 7 degrees has given satisfactory results.

Effect of Faulty Weight Distribution—Fig. 8 shows also how a faulty distribution of weight may, under circumstances, give rise, if not actually to wobbling, at least to some disturbances in the steering of the car. As a vehicle moves along, overcoming its own inertia, this latter can be rightly considered as a force T applied at the centre of gravity G of the vehicle, and

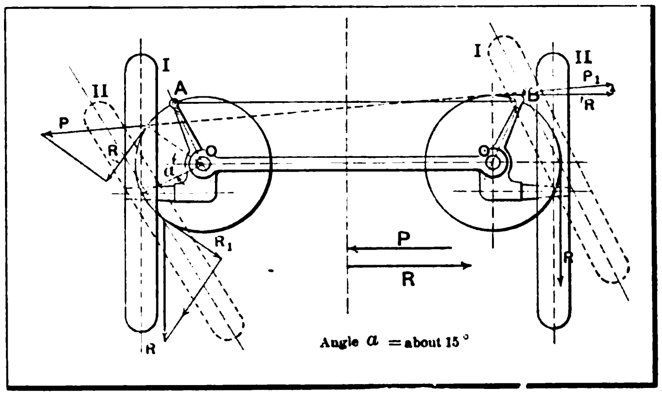

Fig. 6—Illustrating a modification of the type shown in Fig. 8

acting in the opposite direction to that in which the car is moving. It will be seen that if care is not taken to equally distribute the weight, the center of gravity will be no more on the axis of the vehicle, but on one side of it, at a certain distance a. At this new centre of gravity G1 the force of inertia is now applied, while the power is still acting at the two back wheels, or which amounts to the same, at the point O. A couple whose lever arm is a is thus produced, tending to pivot the whole car round its hind wheels; the front wheels will therefore be inclined to slide to the left, resisting power against this tendency through their friction to the ground.

As soon as the engine is declutched the force of inertia instantaneously reverses its direction, and the front wheels are now inclined to slide to the right. It is easily conceivable that thus a tendency may arise to make both front wheels strike to the right and to the left, which tendency, by bad workmanship and undue amount of play and wear, may also result in wobbling of the front wheels.

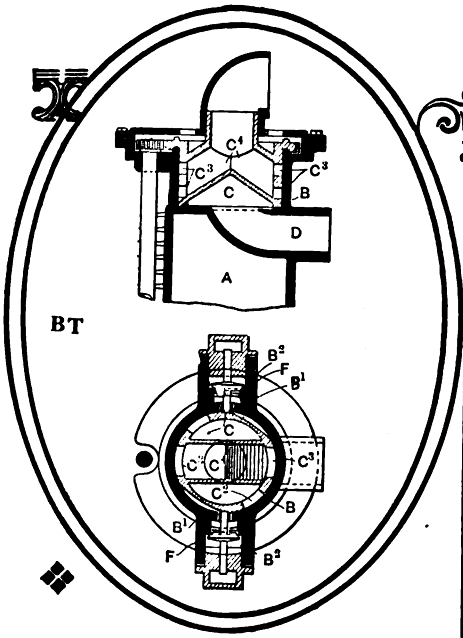
Accurate Registering of Wheel Lock.—Another very important condition that every well-designed steering should fulfil is that the steering wheel should be turned to the same angle for an equal lock to the right and to the left of the steering wheels.

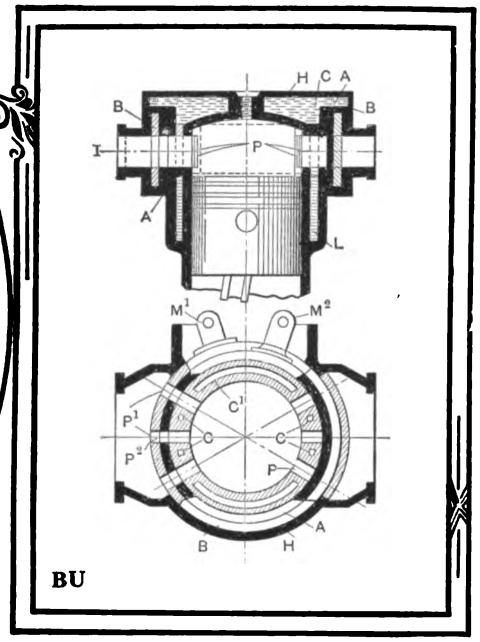
Referring to Fig. 8 again, it will be seen that for the neutral position I of the steering wheels, the corresponding position of the quadrilateral is O1 O1 A1. For a lock III to the left, the steering lever A moves a certain amount corresponding to an angle b, while for exactly the same lock II to the right, the angle to which A will have to move is undoubtedly greater, and in our case equals a. It is assumed, as required by the condition mentioned before, that for both locks the point 1 of the steering arm displaces itself the same amount to the right and to the left, its extreme positions being therefore symmetrically placed in relation to the axis of the steering arm when in neutral position. The point A of the connecting bar b and steering lever must, however, make such a movement as to correspond to an angle b in one case and a in the other. It is therefore apparent that the situation of the point A requires careful consideration, although it is a very easy matter to determine graphically the exact position of it. It will be found that if the connecting bar b can be disposed parallel to the axis of the car good results are obtained by placing the lever A at right angles to the steering lever of the quadrilateral; in case the point A of the steering lever is assumed in between the central axis of the vehicle and the point 1 of the steering arm, the angle included by A and the lever of the quadrilateral should be taken equal 90 deg. less angle a, made by the connecting bar with the center line of the car; if, on the contrary, the point A is situated on the other side of the steering arm, the angle between the two levers above referred to ought to be equal to 90 degrees plus the said angle a.

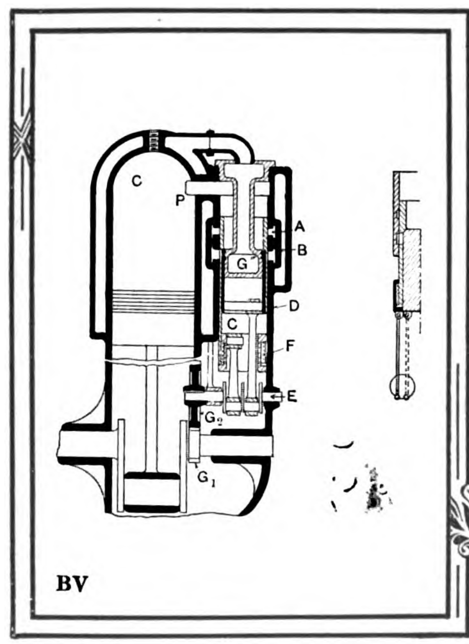
Ball Joints.—It may be said with a full degree of assurance that the steering is such an important function of an automobile that in its failure, the most serious danger lies. The possibility of a ball-socket joint becoming detached should be provided against in a mechanical and absolutely dependable way.

Valveless Motor Research

Conservative Makers on Lookout for Novelties







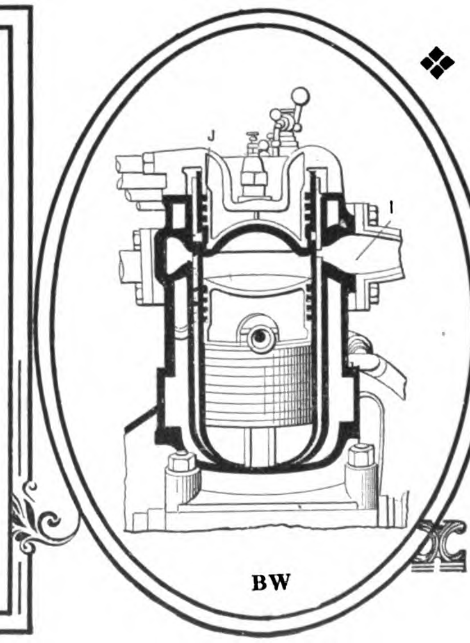


Fig. BT—Showing two sectional views of the Clifton motor together with the rotary valve

Fig. BU—Plan and transverse sections of the Hay rotary sleeve valve motor

Fig. BV—Method adopted by Samain in operating the double sleeves for controlling the gases

Fig. BW—Section through the Minerva-Knight motor showing the shape of the ports

Among the motors here shown is a description of one patented by the Renault Company in France, which, up to the present, has not been incorporated in any of the firm's standard models. Such being the case it must be a warning to inventors that they must not expect that all they have to do is to invent a motor and then cash in.

THERE are certain problems involved in the valveless motor that need more than a dash of the pen to explain or criticise. Familiarity with the practice in vogue in the conventional poppet valve motor will require supplementing in order that the engineer shall be in a position to take the new situation in hand seriously. What was good in the above-mentioned types may prove an utter failure in a valveless motor. There seems to be an idea in some people's minds that the sleeves of some of the commercialized propositions will wear unduly and thus allow the compression to leak.

As far as experience goes this has not been the case and instead of deteriorating motors have shown a tendency to improve. When the length of the sleeves and the large film of oil that surrounds them are considered it must be clear to most people that the gases will follow the line of least resistance, which is out of the ports provided, rather than endeavor to pass between the sleeves. Another point to be remembered is that the carbon generated in the motor acts as a lubricant and fills up the interstices of the metal, thereby eliminating wear. One has only to look at one of these motors after it has been taken down, to be convinced of this fact.

Clifton Motor Utilizes Rotary Valve in Shape of Cam

The mechanism of the rotary valve of a Clifton motor consists of a combination of a cylindrical valve casing B in the cylinder head and an induction passage D leading into the base of the casing, one or more ports B1 in its cylindrical wall connecting to the cylinder A. The rotary valve C fits into the casing B, the valve being opened at the bottom so that its interior is in communication with the induction passage D having one or more inlet ports C2. One or more ports B1 are provided in the wall of the casing B and the passages B2 connect the ports to the cylinder A. The rotary valve has inlet ports C2 leading from its interior which is in communication with the induction passage D, and exhaust port C3 is connected to an outlet in the top of the valve by the passage C4. The ports B1 in the casing B are controlled by an auxiliary lift valve F situated in the passageway B2, in addition to the rotary valve C. An auxiliary valve F is also provided, directly actuated by a cam on and controlling the same port as the rotary valve C. The method of operating this type of valve is shown in Fig. BT.

Hay Motor Employs Two Concentric Rotary Sleeve Valves

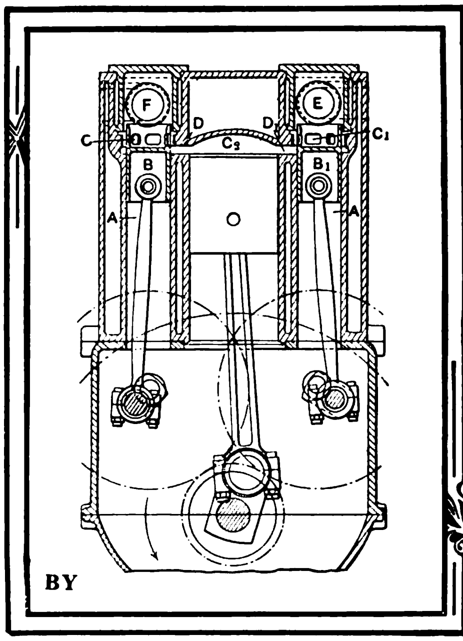
In Fig. BU can be seen the method employed by J. Hay of controlling the ports of a four-cycle motor by means of two sleeves. The cover H which encloses the valves is provided with water cooling in the manner shown and the water space in the head is connected to L by means of a channel. Both sides of the valves A and B have cut in them ports P1 and P2 on the inlet side I. Where the ports are in multiple the port sleeves have passages in them at C, which are necessarily smaller but serve to maintain the valves and other parts at an even temperature. The valves are operated from the crankshaft through suitable gearing through the medium of the half-speed shaft. The arms M1 and M2 are attached to the sleeves B and A respectively.

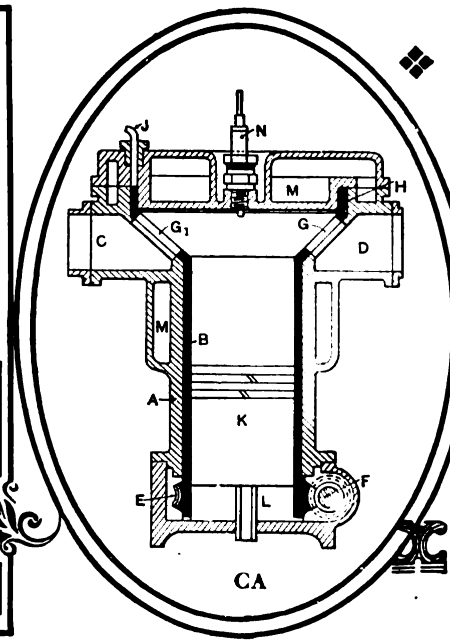
Principles Governing the Gaubert Sleeve Motor

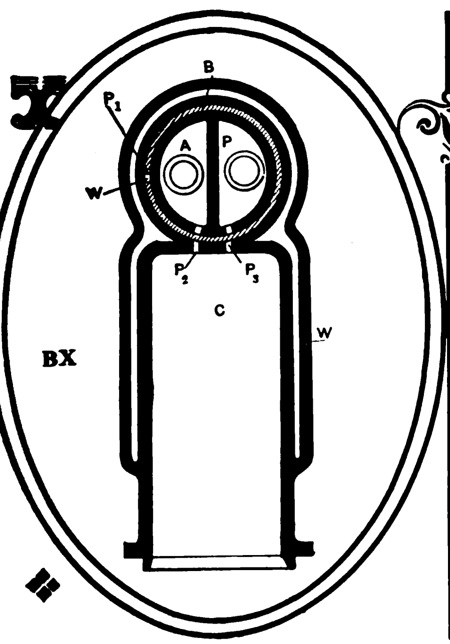
The section of the motor in Fig. CB, the patent for which has been registered by Marcel Jules Marius Gaubert, shows the manner in which a single sleeve operates the ports on a motor of the four-cycle type. Attached to the crankshaft are cylindrical members C with helicoidal grooves cut therein in which pins attached to the ends of the lever H are fitted. The rotation of the cylinder C causes the lever to be displaced laterally, which action causes the sleeves to be drawn down or pushed up as shown on the right-hand side of the section CB.

Minerva Motor Built Under Knight License

The Minerva motor, a section of which is shown in Fig. BW, is built under the Knight patents and has, as can be seen from the illustration, two concentric sleeves interposed between the piston and the cylinder wall. The illustration affords an idea of the method employed by this firm of carrying out such features as motor cooling, the position of spark plugs and in particular the throats of the passageways for the exhaust and intake gases. The inlet passageway I is enlarged at the point where the manifold is attached to the cylinders and narrows down in order to conform approximately to the size of the slot in the sleeve. The junk ring J has four rings and the piston has a like number. The cylinder head together with the piston is so formed that the compression chamber is rendered almost spherical. The position of the spark plug immediately at the top of the sphere relieves the motor of any gas pocketing. The accompanying diagram shows the horsepower curves of various types of Minerva motors, both with the conventional type of valve as compared with valveless motors of the Knight type. The appreciable gain in power in the valveless motor over the other type is more noticeable as the speed increases, which may be due to the fact that motors of this type have very little compression at low speeds, which, however, materially increases with the corresponding increase of the motor speed. In the 16-horsepower type shown at B in the diagram it will be noticed







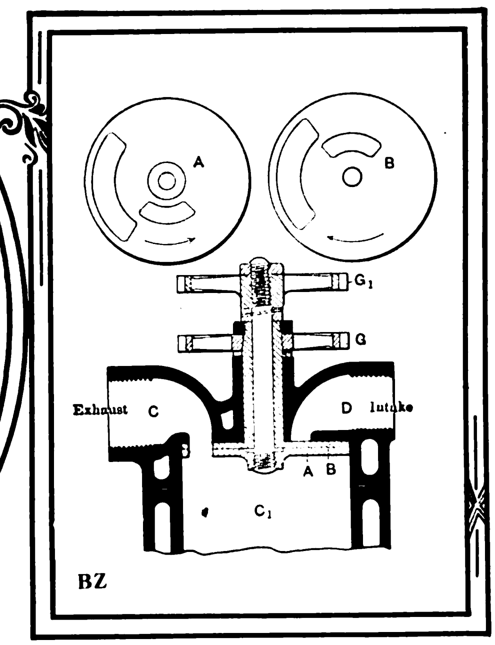


Fig. BX—Section through the Harper motor, in which two sleeves are employed

Fig. BY—The Albion motor, in which piston valves replace the conventional poppet valves

Fig. BZ—Method of operating the disc valves in the Rowell and showing the port openings

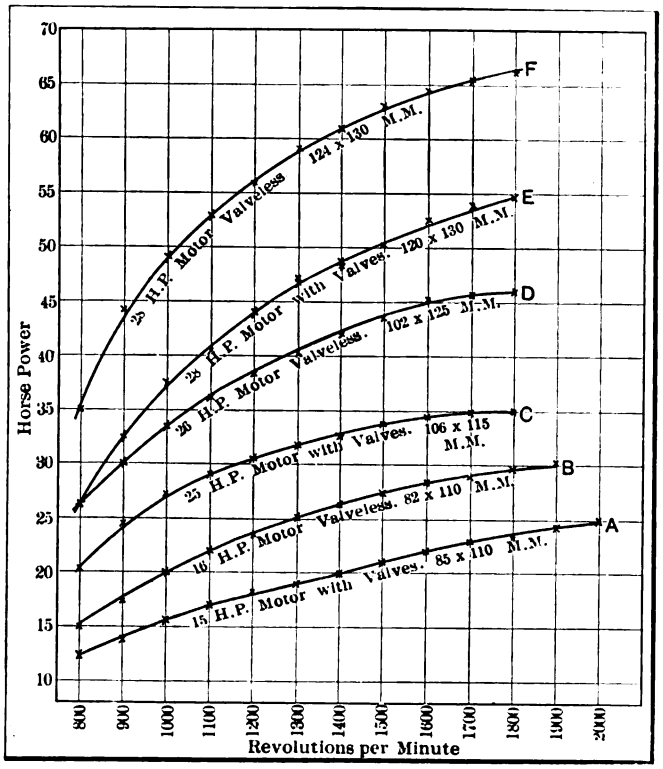
Fig. CA—Section through a cylinder of the Renault rotary sleeve valve motor

that the size of the motor is 3 millimeters less in bore than the motor, the curve of which is shown at A.

Again looking at the curve E at 1,500 revolutions there is a difference of 13 horsepower at this point, whereas at the 800 revolutions per minute of the engine point of intersection there is only a difference of 9 horsepower.

Harper Motor Employs Stationary and Rotary Sleeves

It is possible from the sectional view of the motor shown in BX to see the method by which the regulation of the gases is effected. The cylinder C is water-jacketed at W and W1, the upper portion W1 being in direct communication with W. Two concentric sleeves are situated in the cylinder head and extend the whole length of the cylinders which are necessarily cast en bloc. The inner sleeve A is divided along its entire length by the partition P which makes it possible to utilize it both for the intake and exhaust gases. This sleeve A is stationary, while the sleeve B through suitable mechanism is caused to rotate and



Horsepower chart showing the variations between the Minerva poppet and sleeve-valve engines

allow the port P_1 to command the passage of the gases either in or out of the cylinder through the slots P_2 and P_3. This motor was registered by Harper and Lane.

Piston and Sleeve Valve Used in the Samain Motor

The cylinder is cast with a cylindrical chamber at the side, connected by a port P at the top of the combustion chamber C and provided with passageways A and B, the former being the inlet and the latter the exhaust. Laying between the wall of this cylindrical cylinder and the central water-cooled column is a ported sleeve C and within this is another sleeve D which are actuated by separate cranks upon the eccentric shaft E which runs at half speed. The cranks are set at an angle of 20 to 30 degrees apart. The sleeve C is actuated as regards its downward movement through the medium of a spring F and the top of the sleeve D seats against the shoulder formed at G on the interior of the outer sleeve C. The two sleeves rise together when opposite the intake port A and the relative position of their cranks cause them to separate and put the inlet passage into communication with the chamber and engine cylinder.

During the compression and firing strokes the two valves are moved downward, the port in the outer sleeve being closed as is shown in the illustration. In registering with the exhaust port the sleeve is moved in an opposite direction, opening up the exhaust. The compression space in this motor seems to be considerable. The eccentric shaft E is driven by means of the gear G_1 which is attached to the crankshaft and to the half-time gear G_2. A section of the motor is shown at BV.

Albion Motor is Fitted with Two Piston Valves

The Albion motor shown in section in Fig. BY needs but little explanation. Piston valves operated by connecting rods attached at their lower end to small crankshafts cause the valves to reciprocate in the auxiliary cylinders A. The manifold ports C and C_1 are placed in communication with the working cylinder C_2 and permit the gases to be taken in or expelled from the cylinder through the passageways D and D_1. The gas enters the inlet chamber by the passage E and passes out of the exhaust manifold to the outlet F. The pistons B and B_1 are fitted with expanding rings to insure gas tightness.

Two Rotary Disc Valves Used in Rowell Motor

The rotary disc valves employed in the Rowell motor, as shown in the section of a cylinder head in Fig. BZ, have all the valve faces together with the inside face of the combustion chamber first turned flat and afterward ground. The ports C and D are for the exhaust and intake respectively. The valves A and B are caused to rotate inside the cylinder C_1 by means of gears G and G_1 in opposite directions, thus increasing the opening and closing speed. The inlet port opens and closes on dead centers,

New Models and New Methods of Painting

In the present article by M. C. Hillick attention is called to the fact that the choice of colors for body painting should have some definite relation to the appearance of the body. Paint is intended to bring out the lines of the body and emphasize the builders' art. It is little use to treat all body surfaces alike, for each requires special handling.

THE changing times imply changing methods, and the variations, however small, in style, design and model, which find expression in the 1912 car, invite—in fact, compel—some distinct, yet, perhaps, apparently minor, change in the practice of painting formerly in favor.

Painters in common with automobile owners and users are alive to the fact that the style and design—or the model, if you please—of the car body must govern to no small extent the choice of colors to be applied. In the future, at any rate, this principle will find recognition to an extent hitherto unknown.

First a study of the model, its needs—everything, in fact, that it must have to give it a compelling power of attraction—and then a scheme of color adornment in the highest degree effective to develop all the fine and shapely attributes of the car. To accomplish this result both the painter and the car owner, or the painter acting upon the authority of the car owner, must have color sense, or as it is commonly understood, "an eye for color."

This end is not gained by a lavish employment of various colors upon any single car, but rather by a simple color design in which the form of the car is not blotted out or overcast by some meaningless combination of pigments.

The mission of color is not to detract from, nor to conceal, the grace of the fashion of the builder's design. It is in the dignity of the car, and to whatever extent it fails, to that extent, we must understand, it fails in its appointed office.

The pressed steel, or, perhaps we should say more explicitly, the pressed steel sheet automobile body, will to a certain extent necessitate a method of surfacing and painting somewhat different from that which obtains under the use of the present body material.

Pressed steel surfaces, unless they come to the painter with a coat of enamel baked on, over which the paint and color structure and the varnish are forced to find a foothold, require a special treatment of which the best is a thorough sandblasting. This treatment eliminates all rust and scale formation, and insures for the subsequent coatings a foundation as honest as the heroes of ancient days.

Over this sandblasted surface a coat of metal primer—a material that dries hard and firm, yet sufficiently elastic to enable the paint fabric to respond to all the laws of contraction and having a radial opening of 90 degrees × the width of the port, which can be seen in the illustration. During the compression and firing strokes the ports on opposite sides of the combustion chamber are closed by the solid parts of the valves. The exhaust port is given a lead of 10 degrees for each valve, thereby obtaining an opening of 20 degrees × the width of the port, which will give an opening with the lead of 20 degrees to the crankshaft, which, however, can be altered. By the time the piston has traveled half way up the cylinder on the exhaust stroke there is a radial opening of 100 degrees × the width of the port. The valves are drawn up to each other by means of spring washers which will give in case of expansion. The design of this motor relies upon a film of burned oil and carbon between the valves as

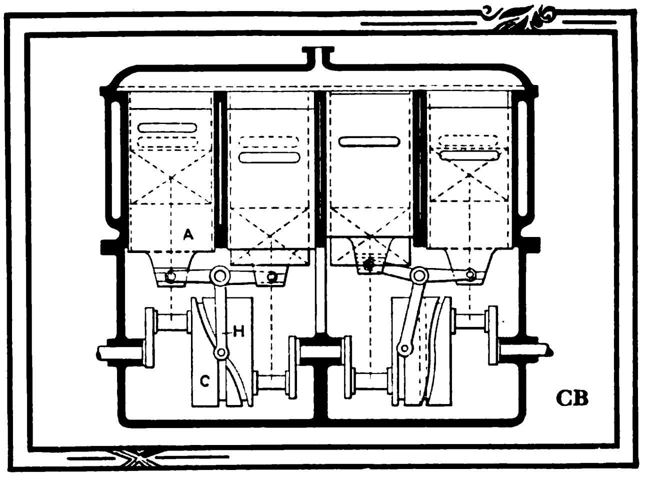


Fig. CB—Transverse section of the gaubert motor showing the method of reciprocating the sleeves

a lubricant. Apart from the shape of the ports there is nothing novel in this motor and if the question of priority should ever come up for decision this type of motor will undoubtedly furnish several claimants.

Renault Rotary Sleeve Valves Show Originality

As has previously been stated in the columns of THE AUTOMOBILE, conservative and old makers of cars are not letting the grass grow under their feet in the matter of new types of motors. The section of the motor shown in Fig. CA is of the design patented by Louis Renault. It will be seen that there is a cone-headed sleeve B placed concentrically within the cylinder A. The sleeve is provided with four ports formed in the cone section at G and G1. The sleeve is caused to rotate through the action of the screw wheel F which engages with the helicoidal rack E. By these means the cone-headed sleeve is rotated at a speed required to close the ports to coincide with the two openings C and D as required for induction and exhaust. The speed of the sleeve is one-eighth engine speed. The outer flange portion of the sleeve above the cone is made with three grooves as shown at H for the accommodation of three compression rings which assist in forming a gas-tight joint.

In order to allow for the necessary additional period of exhaust opening as compared with inlet opening the ports in the cylinder heads are not set diametrically opposite to one another as in conventional practice. It is intended that the inlet ports shall open 10 degrees after the upper and close 25 degrees after the lower dead center. The exhaust will open 40 degrees before the lower, and close 5 degrees after the upper dead center. This gives an induction opening of 195 degrees and an exhaust opening of 225 degrees, the travel with all ports closed during the compression and explosion moments of the piston being 295 degrees and between the closing of the exhaust and the opening of the induction port 5 degrees with ports closed. An oil lead at J is provided for the lubrication of the upper extremities of the sleeve, suitable grooves being provided to conduct the oil to the sleeve proper. The shape of the combustion chamber formed by the cone head does not follow the practice set by other designers of valveless motors.

WATER IN CYLINDERS MAKES FOR TROUBLE—Frequently it is found that water passes into cylinders through defects in castings in which slag is enmeshed or due to misplaced cores. A large number of cylinders are so designed that the plug in the cylinder heads fail to satisfy the requirements and water finds its way into the cylinders as a result. The defective plug is inadequate, and a plug (bronze) may be screwed in, forming the connecting link between the inner and the jacket doors. In service due to differences in heat the thread on the plug is liable to strip at the inner dome and water will readily pass into the cylinders.

---

expansion—should be applied. Not only contraction and expansion of the steel sheets, but their action under the strain of service vibration and roadway oscillation must, so far as possible, be overcome through the resilient nature of the priming and primary surfacing mediums.

To what extent the steel sheet automobile body will be used is hardly within the bounds of conjecture, but it is an issue which the painter will be forced to meet and plan to surmount. It is an issue, moreover, that the car owner will be vitally interested in, since appearance, and the cost of maintaining the appearance of the car depends in the last analysis upon whatever degree of durability the painter is able to establish.

Upon the primer here referred to should be applied, in due time, a surfacing coat of body and substance, touched off with enough raw linseed oil to yield a good and elastic foundation upon which, after two or three days' drying out, the necessary puttying may be done. The main thing which the painter needs to attend to at this stage of the work, and which the car owner and the party selling the car expect him to attend to, is to stop up the surface with a resolute body of pigment, supplementing this by puttying, and putty glazing any and all existing surface defects—developing, in a word, a flawless and an exceedingly strong foundation.

In all steel surfaces over which a fine, mirror-like finish is desired the first principle involved is to secure a depth and power of pigment that may be rubbed down with artificial pumice stone to a perfectly level and smooth surface without at any point laying bare the metal beneath.

As a means of avoiding this condition of things many of the best craftsmen have adopted the practice of using the rubbing stone dipped in benzine instead of water. This insures the surface from dampness, in case of getting through to the raw metal and from all the trouble following in the make of moisture.

For a high-class finish one coat of primer, one coat of filler, and four straight coats of roughstuff are needed.

All these materials may be bought, and economically bought, we believe, ready mixed and fit for the brush.

Their application deserves to be on a plane with the quality of the goods, and the painter owes it to himself, and to the present owner or prospective buyer of the car, to see that such is the case. Workmanship and quality of materials employed should precisely match if out of the combination we are to have the issues of life and length of day for the car surface.

Over the foundation above referred to belong two coats of the selected body color, with a coat of varnish—color or glaze coat to be flowed over these. Then in some cases, depending, of course, on the color selected, an additional coat of glaze or varnish color will be required. Usually this last varnish-color or glaze coat carries less pigment and more varnish.

After this coat is rubbed lightly with water and pumice stone flour the striping and ornamentation is applied over which is next flowed a coat of clear rubbing varnish. In due season this coat is rubbed thoroughly and uniformly with water and pumice stone flour, washed and cleaned, and finished with a varnish of the best body and brilliancy.

Letters Answered and Discussed

Description of Flywheel Fan

EDITOR THE AUTOMOBILE: [2,790]—Would you publish in your columns a description of the type of fan known as the flywheel fan? Is the fan separate from the motor or does it perform the office of a flywheel as well as that of a fan? I would appreciate any information that you may be able to give me on the subject.

C. R. STURGESS.

Penmar, Pa.

The flywheel fan is in common use. It is an integral part of the flywheel, the fan blades being the spokes of the wheel. The accompanying illustration (Fig. 1) shows the method of casting the fan. It is of use in exhausting the heated air from the motor and must be installed beneath a closed hood.

Duryea Has Last Word

Editor THE AUTOMOBILE:

[2,791]—I grant the willingness to stick to the original question, also that an unbroken film is desirable. But you have not said what that film shall consist of. Water is a good lubricant for certain bearings. Soap-suds produces the finest films in the world and is often used for lubrication. Many oils contain soap; rosin is often present; paraffin wax is very common; kerosene is frequently found, and even gasoline in small quantities is not appreciably harmful. So your belief that a film of lubricant cannot be reasonably well secured unless the oil is free from adulteration is certainly far from having fact as its foundation. There is very little pure oil used. Most of it contains some adulterant or other, and many oil dealers will tell you the adulterant adds body and permits the "film" to do its duty. Your argument that only 1 per cent. of the users use the mixture system and therefore it stands condemned, is sheer foolishness. You can easily remember the time when no one drove an automobile, for there were none. The great majority of road users to-day still drive horses. It surprises me that you do not follow their lead and get onto a horse paper.

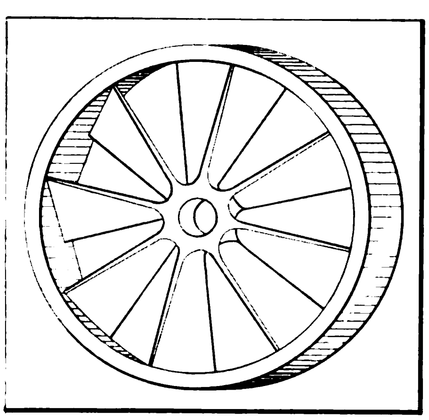

Fig. 1—Common form of flywheel fan in which the vanes of the fan are formed by the spokes of the wheel

Announcement

MY 1912 AUTOMOBILE

So much interest is being taken in the coming 1912 models that already criticisms are being heard to the effect that the 1912 automobile is not meeting the expectations of many readers of THE AUTOMOBILE. *In order to discover exactly what are the conceptions of the many readers on the 1912 machines* THE AUTOMOBILE *starts this week a discussion on the 1912 models and hereby invites every reader to mail in what are his or her conceptions of next year's car. The information given should include such points as:*

Horsepower	*Tire sizes*
Bore	*Rear axle*
Stroke	*Front axle*
Ignition	*Control parts*
Lubrication	*Body features*
Carburetion	*Equipment*
Clutch	*Cylinder type*
Gearset	*No. of cylinders*
Drive	*Cylinders, how cast*
Springs	*Price*
Wheelbase	

In addition to giving these details the reasons for your points of selection should be stated concisely and clearly.

As a benefit in the matter of comparison some details of the average cars for 1911 are given herewith, these details being for cars selling at $1,000 or thereabouts; $1,500 or thereabouts; $2,500 or therabouts, and $4,000, thereabouts and up.

Each communication must be legibly written on one side of the paper only; it must be properly signed with the writer's full name and address, and if the writer does not wish his own name to appear in print he may request the use of any nom de plume.

Any reader desiring to make line drawings, showing details of his ideas of his car or some of its parts, is requested to do so.

Editor THE AUTOMOBILE.

You are utterly wrong in this matter. The Holsman engine as now made offers no difficulty at all to avoid carrying the mixture into the case, but on the other hand the designer goes out of his way to do this thing. He carries the mixture in and then out again just as any engine-maker can do, and quite evidently does it to get the perfect lubrication feed.

The real question is, Will a mixture method of feeding oil serve as well or better than a complicated mechanical feed? The answer as proven by many users and years of time is that it is better. No prejudice or argument can change this fact. It is a fact and will remain so no matter whether the public or the press believe it or not. My point is that you damage the public by misstating or hiding the real facts. I have no patent on the method, nor did I even originate it. I have used it exclusively on my limited product for some years. I know it is best. You will not need to live long to see several other tenths of 1 per cent. using it.

CHAS. E. DURYEA.

A New Starting Handle

Editor THE AUTOMOBILE:

[2,792]—I was very much interested in a story which recently appeared in your paper regarding the way the average starting handle is put in place without any apparent regard for the comfort of the man who is to crank the car. My interest was to a great degree accentuated by the fact that my hands have undergone the same tearing process as was illustrated in that story. My object in writing you this communication is not, however, to wail over the evils that be, so much as to find a remedy therefor. In other words could you suggest a form of starting handle which will do away with the bad features you have named?

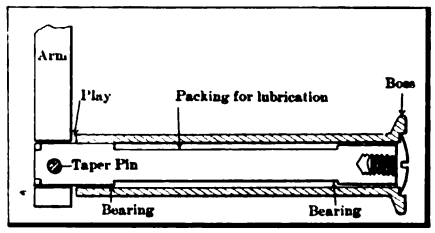

Fig. 2—A suggested form of starting crank in which the play is slightly exaggerated for the purposes of illustration

CALLOUS.

Reading, Pa.

A form of starting handle we might suggest is shown in Fig. 2, which explains itself. The play is exaggerated slightly to show better where it should be. The materials may be of anything suitable, such as a bronze core with a wood handle, or a brass handle, as preferred. The packing, if two metals were employed, may be a composition of white lead and tallow.

Geometric Information Required

Editor THE AUTOMOBILE:

[2,793]—Could you kindly inform me through your columns the names of the two geometric curves used in laying out gear teeth and how they are generated?

Worcester, Mass. STUDENT.

The two curves you refer to are probably the epicycloid and the hypocycloid. The epicycloid is the curve generated by the circle rolling on the outside of the pitch circle and the hypocycloid that generated on the inside. Cycloids are the resulting curves when the pitch circle has an infinite radius, or in other words, is a straight line.

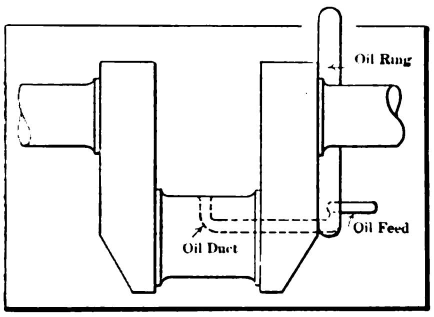

Fig. 3—Method of fitting centrifugal oil ring to crank throw. The oil duct is shown

In Need of a Glasscutter

Editor THE AUTOMOBILE:

[2,794]—I would like to have sight holes cut in the glass of my wind shield. The size of the holes required is from 6 to 8 inches in diameter. I notice some of these sight holes are equipped with glass coverings. Would you kindly let me know who does such work. C. P. FIELD.

Peekskill, N. Y.

Any good glass cutter or wind shield maker will do the work you mention.

Does Not Get Enough Oil

Editor THE AUTOMOBILE:

[2,795]—My motor is lubricated by the splash system and so far as the cylinder lubrication is concerned there is no cause for complaint. The main bearings are also lubricated by the same method and are supplied with enough oil to amply lubricate them. In fact, the oil is led into the central main bearing before flowing into the splash troughs. The connecting rod bearings at the crank end, however, are not sufficiently supplied and I would appreciate it greatly if you would tell me of some means whereby I could increase the supply of oil to these bearings.

EKTON PIERCE.

Coytesville, N. J.

One of the most satisfactory methods of lubricating the crank pin is by means of a centrifugal oil ring. This ring or disc is fitted against the crank cheek and is bent or stamped so as to have a hollow rim which collects the oil naturally sent to it by centrifugal force. A duct or lead as shown in Fig. 3 is fitted within this rim and a hole is drilled, as shown, into the crank pin in case the same is not hollow. If it is hollow, the drilling is of course unnecessary, except the lateral drilling from the surface of the pin. If for some reason it is impossible to fit the oil ring, and the construction of the connecting rod cap permits, a hollow scoop spoon may be fitted which will lead the oil directly into the bearing. If information is desired on the method of attachment we will gladly supply it through these columns.

Repaired Float as Directed

Editor THE AUTOMOBILE:

[2,797]—I repaired the leaky carbureter float as directed in your columns and found that I could get the old gasoline out better by boiling than by blowing it out. I hope this "tip" may be of use to some reader.

Kingston, N. Y. R. T. CORRY.

Wants Information on Keys

Editor THE AUTOMOBILE:

[2,796]—I was very much interested in your reply to query 2,773 regarding the size key to use for a given shaft, and whether one key was as strong as two. In thinking over the subject it has occurred to me that the matter of the length of the key would enter into the discussion as well as the other dimensions given in your columns in reply to the above query. I would greatly appreciate your views on this subject, as well as an analysis of the failure of the key; that is, if it fails by shearing or by some other method of fracture.

J. SCRIVENER.

Newport News, Va.

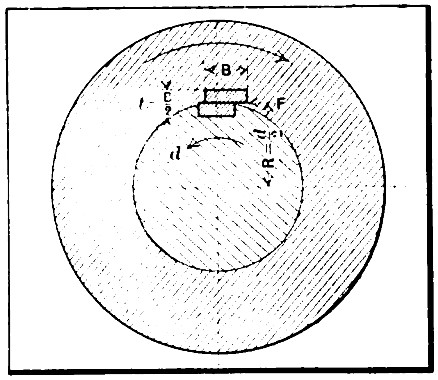

Fig. 4—Illustrating the method of failure by shear of a key and the relative dimensions used in common practice

In the design of a key the ideal condition is obtained when the ultimate shearing stress of the key is equal to the total resistance against crushing. There are other considerations entering into the problem which cannot be overlooked, among these being the wedge effect when the key is a tight fit which overcomes the crushing strain to a considerable extent. Working out an expression for length by Spooner's method:

$$\frac{d^3 \pi f_s}{16} = \frac{F d}{2} = L B f'_s \frac{d}{2}$$

and therefore $L = \frac{d^2 \pi f_s}{8Bf'_s}$

assuming that we wish to determine the length of the key in terms of the other quantities, and the strengths of shaft and key are equal. Referring to Fig. 4, L equals the length of the key; B, the breadth; t, mean thickness or B|2; f_s, safe shear stress of shaft per square inch; f'_s, safe shear stress of key per square inch; F is safe shear force on key, equal to LBf's, and T is the moment of resistance to twisting of shaft equal to $\frac{d^3 \pi f_s}{16} = \frac{F d}{2}$.

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

A series of short stories that will tend to keep the automobilist in touch with matters mechanical and otherwise, covering a field of information that although usually well tilled, needs frequent and careful cultivation to produce the greatest results.

CARBURETERS BLAMED WITHOUT CAUSE—Whenever the engine has been misbehaving for a length of time and the owner of the car has reached the conclusion that it behooves him to do a little tinkering and thus cut down the repair bills, he will almost invariably start to work on the carbureter, no matter what the previous symptoms may have been. In doing this he not only exercises a commendable spirit of economy but a very unenviable lack of foresight. Any carbureter will balk if it is clogged with foreign matter or if it is not regulated so that the best carburetion may be had at the greatest range of speeds; but when an inexperienced motorist—or perhaps an experienced motorist and an inexperienced repairman—starts to work with a hammer and screw driver the result is very sure to be not only a balk but a permanent disinclination on the part of the carbureter to work at all.

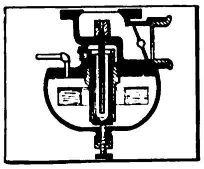

Fig. 1—Type of carbureter known as float feed, in which the supply of gasoline is governed by a cork or hollow copper float, either type being common

The symptoms of carbureter trouble are sometimes rather elusive, it is true, but they may be located by a careful process of elimination which will after a while bring the searcher down to the heart of the matter. If the trouble is finally located in the carbureter and the matter is a lack of suitable adjustment and not a piece of cotton waste in the needle valve or other foreign matter the adjustment will have to be systematically taken up and not done in an erratic fashion, as this will only lead to greater trouble and dismay on the part of the operator. Almost any carbureter on the market will give very satisfactory service for a limited range of action, but this range is often found to be too small, and it is then that the carbureter needs adjustment. The action of the instrument may be all right at low speeds and all wrong at high, or the opposite may be the case, according to the original factory adjustment.

In the case of a float feed carbureter, such as shown in Fig. 1, the gasoline level rises in the float chamber gradually, lifting the buoyant float until the proper level is reached so that the surface of the gasoline is about 1/32 of an inch below the nozzle of the jet and the current of air in passing by the jet will suck the gasoline through the orifice in the form of a spray. After having approximately regulated the gasoline level so that the float will close the needle valve at the proper time the next regulation will be in the way of a proper adjustment for the amount of air permitted to be drawn through the carbureter at medium speeds. After having the carbureter regulated so that it will work satisfactorily at medium speeds with the correct spark advance, throttle the engine and retard the spark; if heating results, close the needle valve opening slightly and observe the action. The needle valve should be closed until the motor does not smoke and runs satisfactorily, then run the engine on medium speed again and make any slight adjustment necessary. The same process should be gone through repeatedly until the motor will run well on both medium and low speeds. The adjustment is then made for high speeds in the same manner with due regard for the auxiliary air regulation if there is any. The difficulties of satisfactory carburetion are, of course, much greater at low speeds than at high speeds and there is a great tendency to draw the liquid gasoline through the manifolds in solid globules instead of the fine spray which is the ideal state in which to attain perfect vaporization the gasoline if drawn through the inlet valve in the form of a liquid will tend to form carbon deposit in the cylinder.

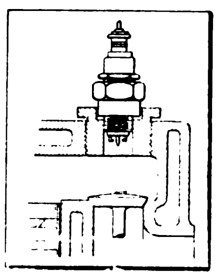

Fig. 2—Illustrating a spark plug which is too short to reach into the combustion space

SPARK PLUGS MUST BE OF CORRECT LENGTH—In fitting spark plugs to the cylinders care must be exercised that they are the correct length so that not only the maximum efficiency is obtained from them but that they are preserved from rapid wear and deterioration. The accompanying cuts, Figs. 2, 3 and 4 show the three conditions. The first shows a spark plug which is too short, the plug being in a recess in which carbon would collect and fill the gaps. The screw threads in this recess also aid in the work of holding the foreign matter in a place where it would soon foul the spark plug. The second plug is much too long, projecting far into the cylinder and subjecting itself to the hottest gases, which will soon cause the end of the plug to glow and thereby cause pre-ignition and after a time fuse the points of the plug together. The last sketch of the three illustrates a spark plug which is of the correct length. The points of the spark gap project far enough into the cylinder to effect the greatest firing efficiency possible, and the plug itself is kept cool by the surrounding walls without having any recess in which the carbon may be caught and held. Before buying the plugs this required length should be determined, as after they are purchased it is a rather difficult matter to make any correction and in most types of plug it is an impossibility. The gap should be inspected before placing the plug into the cylinder, as it is almost impossible to estimate the great losses in power and efficiency which can be traced to a weak or insufficient spark.

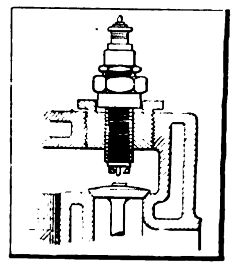

Fig. 3—Method of inviting pre-ignition. The spark plug shown is too long and will soon glow and fuse the points

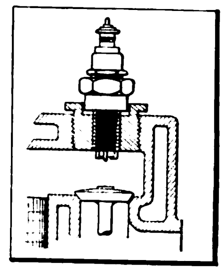

Fig. 4—Showing the proper length of the spark plug, the only part projecting into the combustion space being the sparking points

Be Prepared When Touring—A touring party is, to a great degree, in the same position as an army in that it has to gather its supplies from the country through which it is traveling; hence it is very often possible that many little devices which have been the fruit of experience in the army line may be made excellent use or by the motorist. Such a device is the portable filter illustrated in Fig. 5. Suppose that the supply of water should give out far from any village or else fall so low that there is a great necessity of replacing it. To dip water from the average pool is not an advisable procedure on account of the foreign matter generally contained in such water. The portable filter is designed for just such a purpose, as it may be used for drinking water; indeed, its original purpose is just that.

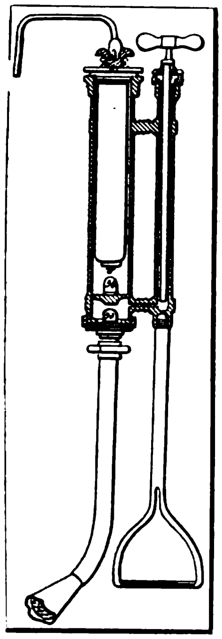

Fig. 5—Type of portable filter in use by the army. It is comparatively light, compact and easily carried

The tube, which has a strainer on the end, is placed in the pool or stream and the handle on the plunger is pulled up. This action will fill the chamber with water, while the down stroke will send it up through the filtering chamber and out of the tube at the top. Besides being of use for radiator water the device can of course be used for drinking purposes and might in this manner prove itself as valuable as when used in the former emergency.

Another great advantage of an instrument of this type is the fact that the capacity is unlimited, while the vacuum bottles which are sold to tourists under various trade names have a very small capacity and hence an entirely limited sphere of usefulness. The vacuum bottle is designed not as a source of permanent supply but to furnish the owner the luxury of a hot or cold drink when such are not readily obtainable. It is by no means safe to drink from a stream of unknown source, no matter how clear and limpid its waters may seem as there are many disease germs which are carried an incredible distance by means of a stream, and although the apparently uninhabited state of the country may indicate that it is safe to risk the few longed-for swallows it is much better and safer to have filtered water when possible. Well water itself is often poisoned, especially if the well is comparatively shallow, by its nearness to foul cisterns or garbage dumps in country houses.

Solid matter within the radiator will eventually be deposited on the radiating walls and greatly impair its utility, and indeed after a time cut down the power of the engine by not adequately cooling parts which cannot stand a higher temperature than that for which they are designed. If the circulation is clogged up the water will also tend to boil and hence form steam which will leak past the joints and by its much greater temperature than the water from which it was formed, greatly augment the deposit of scale on the cellular surfaces.

One Keyway Sufficient to Hold a Shaft—It is not necessary to cut away unnecessary material by making two or more keyways when it is a fact that one key will hold as well if not better than any number if it is properly designed and if the key is of proper material. In the accompanying cut, Fig. 6, D is the diameter of the shaft, W the width of the key, A the depth of the keyway and R the radius of curvature of the edges of the keyway. The key is of the correct size when it is of equal strength in all ways, that is, when the resistance to sheer is the same as the resistance to torsional strains. The ideal condition and the one which is made the aim in all the dimensions given by the standard manufacturers, is that in which the moment of inertia of the key about the diameter of the shaft is the same as that of the shaft about the same diameter. To illustrate the size key required for a shaft of common size it may be well to consider a particular case. Take D equal to 1 1-4 inches; W will equal 3-16 inch. A 3-32 inch and R .04 inch. If it were figured out mathematically it would be found that the moment of inertia of the circle less that which was taken away to make room for the key would be equal to the moment of inertia of the key.

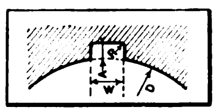

Fig. 6 — Illustrating form of a standard keyway. A, depth of key; D, diameter of shaft; W, width of key; R, radius of curvature of key

Direction of Magneto Current Alternates—As the armature rotates between the two pole pieces in the ordinary magneto the current is generated by the cutting of the magnetic lines of force between the north and south poles of the magnet. Fig. 7 illustrates the armature in diagrammatic form as being in one of the positions taken up during a complete revolution. It is evident that as the armature continues to rotate the part which is nearest the north pole will be nearest the south pole, and the current instead of running from a to b will take an opposite direction. It is thus evident that there is a reversal in direction of the current at every 180 degrees through which the armature passes. Since the current passes through this reversal in direction it is very evident that there is a point where there is no current at all since it would be impossible to change from one direction to the other at the same instant. An examination of the cycle of events also shows that the current becomes less as it approaches this point until it reaches zero, it then increases until it is a maximum after the armature has revolved through 90 degrees from the point of zero current. In magneto timing a point is made therefore, of arranging the gears so that the spark is given at the point of as near maximum current as possible under the greatest number of conditions.

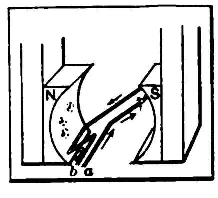

Fig. 7 — Illustrating the direction of the current when the armature takes up the illustrated position. Current flowing from a to b.

Ball Check Valves Much Used—The ball check valve is one of the smallest and most compact forms of satisfactory non-return valve. It is true that this type of valve is occasionally charged with having a great penchant for sticking if great precaution is not used in keeping it clean. The uses for the ball check, however, are so great that in some cases where there are no chances of its fouling, it is practically infallible, as for plunger oil pumps, etc.

In the illustration Fig. 8, a ball check is shown. The liquid is free to flow through the pipe in one direction without any interference on the part of the ball check, but when there is a tendency to flow back the pressure forces the ball into its seating and very effectually checks the flow. It is in the case of the ball being thrown violently into its seating that the sticking tendency makes itself felt to the greatest degree. This is especially so if there is any oil deposit on the seat or if foreign matter has collected there to any extent. In some forms of oil pumps the ball check valves are to a great extent self-cleaning since they are arranged in such a way that the flow of oil takes away any deposit which may have accumulated.

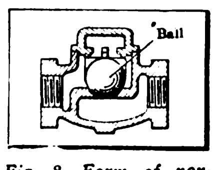

Fig. 8—Form of non-return value known as the ball check, often accused of having a great penchant for sticking

Another cause of sticking in this type of valve is that the balls are often too small and sink into the aperture much further than intended. It does not take much of an indentation to hold the ball firmly in place, while if too large it is apparent that they are apt to become stuck.

Details of the Latest Kissel Kars

Principal Mechanical Features Analyzed

The latest line of Kissel Kars manufactured by the Kissel Motor Car Co. of Hartford, Wis., gives the buyer the choice of four types of chassis with a very complete assortment of bodies. Three models are fitted with four-cylinder motors, the 60-horse-power, however, being fitted with six.

IN order to meet a varied demand the Kissel Kar is made in four types of chassis, commencing with the 30-horsepower runabout, selling at $1,500, to the six-cylinder, 60-horsepower limousine. The outstanding features of the body construction are shown in Figs. 1 and 2, fitted respectively to a 50 and 60-horsepower chassis. The general construction of the various types is uniform, and the motors have the cylinders cast in pairs. Fig. 4 illustrates the motor of 60 horsepower looking at the inlet side. The cylinders are cast in pairs with L-heads, the valves being placed all under one side. The general neatness and clean appearance of the motor is enhanced by the valve covers C1, C2 and C3 which are readily removed by unscrewing a single thumb nut for each cover. The crankcase of the motor is cast from aluminum in two halves. The lower half forms a well and oil is forced from a special tank by a gear-driven pump to every section of the motor. An oil level is provided allowing the flow to be adjusted to meet any condition automatically. The oil pump P is shown on the right-hand side of the motor in Fig. 4 and it will be seen that there is a lead taken direct from the lower half of the base chamber and after passing through the pump the oil is forced back into the motor through the lead O. The shaft driving the pump is operated by means of double

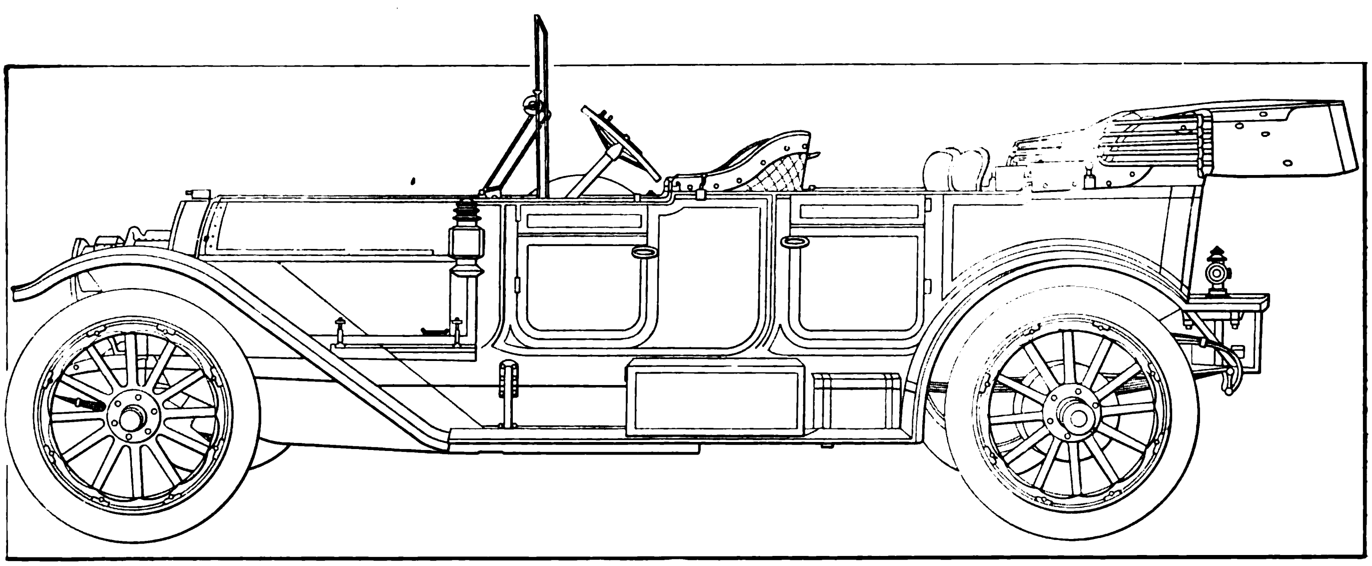

Fig. 2—General appearance of the six-cylinder 60-horsepower touring car with flush-sided fore-door touring body for seven passengers

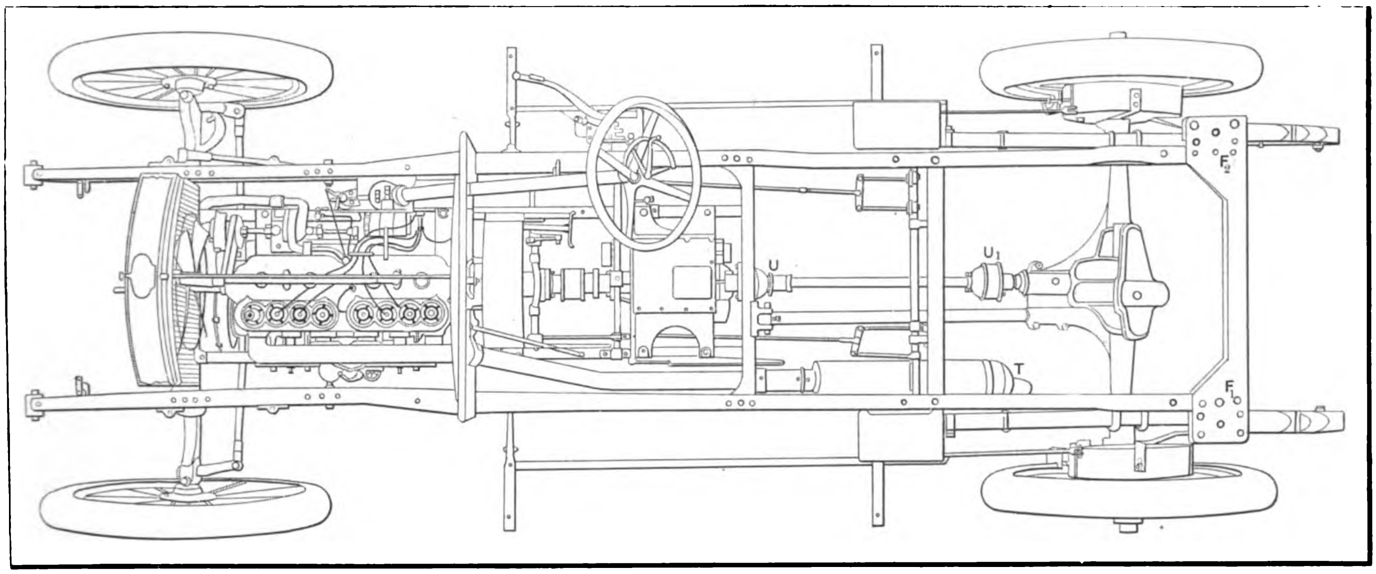

Fig. 2—Plan view of the four-cylinder 40-horsepower chassis showing the **general arrangement** of the units

gearing off the end of the camshaft and has a split joint to facilitate the removal of the pump without disturbing the gearing.

In addition to grinding the motor parts to size in Kissel motors they are first ground and afterward lapped by a special machine with the part within which it operates. The cylinders of the 60-horsepower motor have a bore of 4 1-2 inches with a stroke of 4 3-4 inches. The intake manifold is branched at three points and is attached to the cylinders by means of brackets B which are held in position by a nut. The same brackets serve to hold the exhaust manifold E in position, but it is possible to remove the intake manifold by undoing the center stud without disturbing the exhaust manifold. The intake manifold at the point where the vertical pipe from the carbureter meets the former is of larger diameter than the remainder of the piping. This allows for a certain degree of expansion and prevents the choking of the gases, which is one of the difficulties to be overcome in carburetion for six-cylinder motors. The water pump is driven by a shaft which carries the fan pulley on the opposite side of the motor, from the half-time gearing, and the water leads W3, W2 and W1 are connected by the piping P2 and P3, whence the water is delivered to the radiator, which is of the tubular type.

The ignition is furnished either by a Mea or Bosch dual system to spark plugs placed over the intake valves. Compression and priming cocks are provided and fitted in the valve covers over the exhaust valves.

The carbureter C is on the float-feed type with the mixing chamber heated by water from the water circulating system.

Passing to the four-cyclinder motor shown in Fig. 6 it is possible to examine the method employed of operating the pump and the magneto. At the base of the cylinder on the right-hand side there is a drain cup C2 which permits the driver to drain all the water from the cylinders in frosty weather. Such a provision, sometimes overlooked, is an absolute necessity and it is essential that drain cups should be placed at the lowest point of the circulation to allow of every drop of water being drawn off. A similar provision is made below the pump. The pump is fitted with two packing glands fore and aft together with greasers, and the extension of the pumpshaft is fitted with an Oldham coupling G1, which permits the magneto M to be removed readily. The magneto M rests on a ledge cast integral with the motor and is held in position by means of a bridge H. The bracket B is bolted to the motor casting and the bolt passes through this and secures the bridge in position above. Studs are provided in the ledge below which fit into countersunk holes in the base of the magneto.

The motor is suspended by four arms which rest on a subframe attached to the main frame, as can be seen by referring to Fig. 3. Stand pipes B1 and B2 in Fig. 6 act as breathers for the motor and at the same time serve for pouring oil into the base chamber.

A cone clutch of the conventional type is utilized to transmit the power from the motor to the transmission, a universal joint being placed between the two members to compensate for any disalignment and unevenness of the road which might cause flexure in the chassis. The subframe that carries the motor is extended rearward and attached to a cross-member of the main frame. A general view of the transmission is shown in Fig. 7, from which it can be seen that the shafts are placed vertically

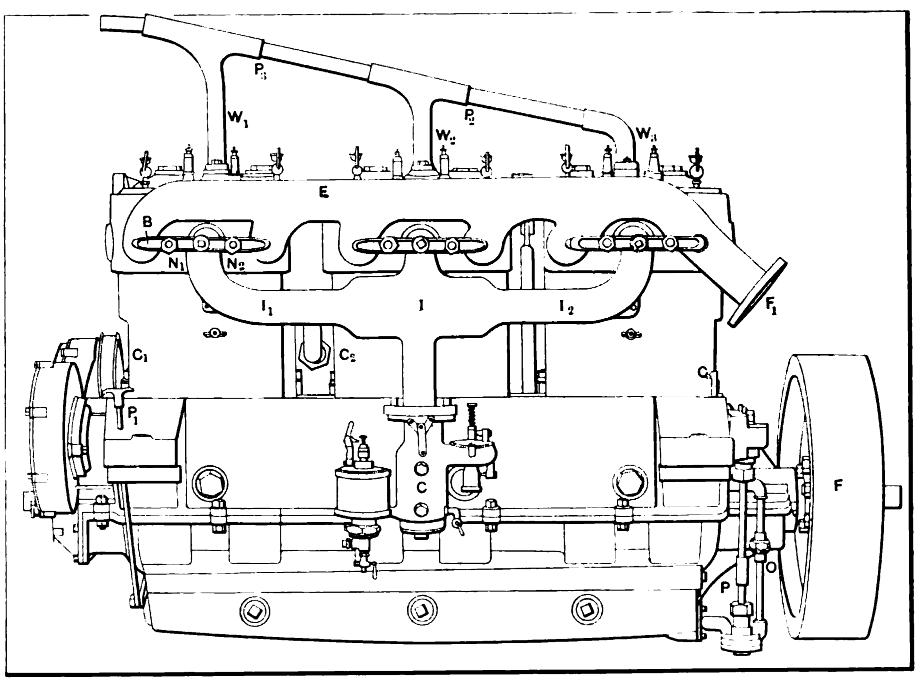

Fig. 4—Left-hand side of the six-cylinder motor showing the carbureter and manifolds together with water pump

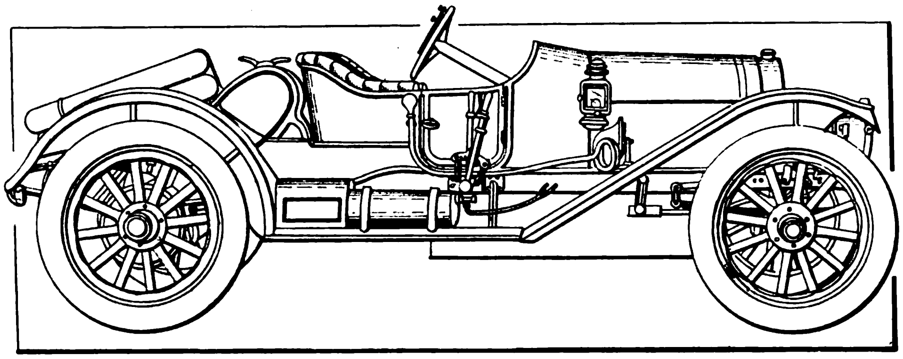

Fig. 5—Right-hand side view of the 30-horsepower semi-racer with gas tank and tires carried on the rear platform

one above the other. The arms A1, A2, A3 and A4 support the aluminum casting from the subframe and the clutch shaft is attached by means of bolts to the flange F1. The primary and secondary shafts are carried upon ball bearings of ample section. The transmission here shown is of the four-speed type as fitted to the 50 and 60-horsepower chassis, but in the 30 and 40-horsepower chassis three speeds obtain. The gear wheel G1 carries a series of dog catches which when engaged with a corresponding set of dogs on the gear G2 forms the fourth speed direct drive or third as the case may be. Gears G1 and G2 serve respectively for the first and second speeds. The gears slide upon a castellated shaft and are moved into position by the lever arms L1 and L2. A cover C is provided at the rear end of the striking arms A to exclude any dirt from this part of the mechanism and to retain the lubricant necessary for easy operation. At the rear end of the gear box attached to the primary shaft there is a flange F2 with arms to take the cross head of the forward universal joint. The propeller shaft, being fitted with two universal joints, one at each end as shown in Fig. 3. is not inclosed and the torque from the live rear axle is taken up by the torque member running parallel to the propeller shaft and terminating at its forward end in a swivel bracket attached to the cross-member frame. The rear end of this member fits into a sleeve of the rear axle and is held in position by means of two bolts. A general idea of the rear axle can be obtained by referring to Fig. 8. It is of the full floating type, the shaft S1 being connected with the dog D1 which engages with the hub of the wheel. The wheels are carried upon roller bearings B1 and B2 which are securely held in position by the locking nuts L. The jaws J1 and J2 accommodate one of the two universal joints and a suspender bar is placed below the axle and is fitted with an adjusting piece B3. The rear side of the axle casing proper is fitted with a cover C1 which when removed allows the differential to be taken out of its housing after the jackshafts have been removed.

Particular attention seems to be paid to one of the most vital parts of the car's mechanism. The method of operating the brakes is shown in Fig. 4, which are of the internal expansion and external constricting types operating upon a drum which is attached to the rear wheels and having a diameter of 14 inches and a width of 5 inches. In order to prevent the external constricting brakes from rubbing on the drum and chattering, springs S2 and S3 are provided and the locking screw A1 holds the brake band in such a position that it cannot exceed the limits of which this screw is set. The lever L1 operates the internal brakes, while the external brakes are taken care of by the lever L3. Fig. 3 shows the method employed for compensating the action of the brakes, the cross bar being carried by short arms attached to the cross-member of the frame.

The wheelbase of the respective models is as follows: Thirty-horsepower, 116 inches: 40 horsepower, 118 inches; 50 horsepower, 124 inches, and 60 horsepower, 132 inches. The front axle is an I-section drop-forging and the connecting bar for the steering arms is placed behind the rear axle. The suspension of the car is taken care of by semi-elliptic springs at the front end and three-quarter elliptic at the rear, the half springs being securely held in position by the frame extensions F1 and F2, shown in Fig. 3.

A neatly designed semi-racer is turned out by the Kissel Company, an illustration of which is shown in Fig. 5. The brake and chain speed levers are placed outside the side doors of the body in order to accommodate the tires of the rear platform; the gasoline tank, which is of oval formation, is placed slightly at an angle.

In the matter of equipment it is the policy of the Kissel Company to include in the purchase price practically everything that the autoist finds it a necessity to have on the car, and on the larger models there should be little else for the purchaser to buy in the way of extras after the car is delivered.

Shock Absorber Idea Old

The idea of a device for arresting the motion of a body gradually and hence without shock is not of very recent origin, but has been used with success in a great many instances where heavy moving weights have to be brought to rest in a short space of time without undue strain.

ONE of the oldest schemes is the shock absorber idea; it had its inception when railroad trains were brought into vogue, and the so-called bumper on a freight car would be incomplete without a shock absorber. In freight-car work, where the shock absorber has to contend with strenuous conditions, there are two principles in common use, on of which depends upon the action of a spring, and the other upon friction. Discussing these two principles, it will be readily appreciated that the spring idea takes into account the desirability of gradually absorbing the energy stored in the moving mass. Spring bumpers produce train oscillations, due to the fact that the springs give back, in a reactive sense, the energy stored in them, and enough work is done in the form of oscillations to absorb the energy of impact of the cars as they bump into each other. That the energy must be absorbed before the cars will be brought to rest is self-evident, but a more quiet way of obtaining the desired result is represented in the form of bumper that dissipates the energy through the medium of friction, which is the

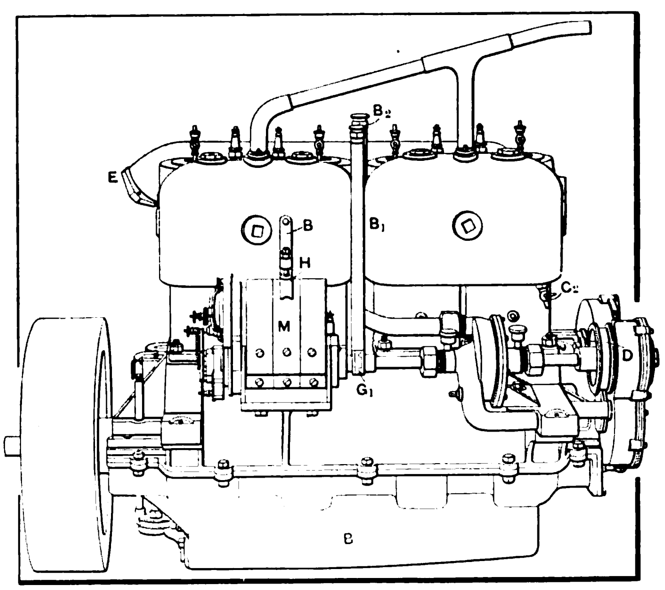

Fig. 6—Magneto side of the four-cylinder motor showing the method of drive and attachment

second principle involved. The friction bumper has no reaction component; all the work is dissipated in the form of heat. As regards the instability of some forms of shock absorbers employed in automobile work, it can only be explained on the ground that the method of utilizing the principle is too frail. If bumpers can be made which will do the work in freight-car practice, involving long trains, surely they can be so contrived that they will serve perfectly in stopping the vertical bounce of the chassis frame and its load as represented in an automobile. Some designers use these absorbers to supplement work that should be performed by the suspension springs, whereas these latter should be made strong enough to do their allotted work without extraneous assistance.

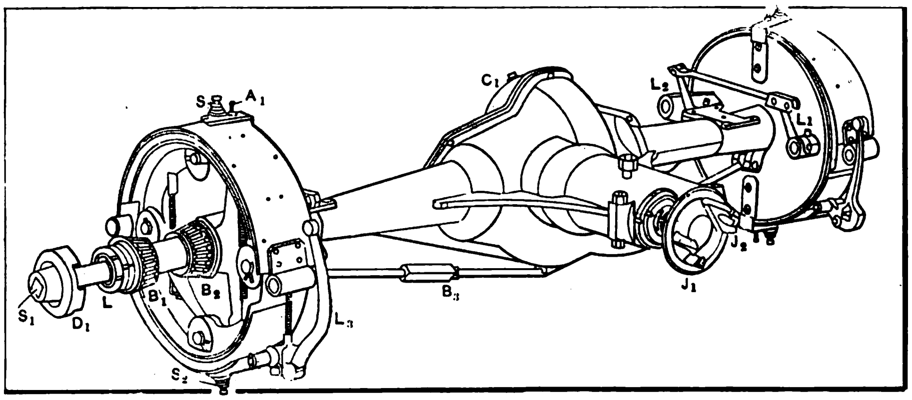

Fig. 8—Live rear axle of the full floating type employed in Kissel Kars

Purpose of the Differential

In turning a curve it is required that one wheel will revolve faster than the other; in order to make this possible the two wheels cannot be on one solid shaft, but will have to be separated by a break. The differential is inserted in this break and makes the difference in speeds practicable.

THE differential gear is fitted, in order to allow one driving wheel to be run faster than the other, in other words, to absorb a greater share of the motion transmitted from the engine, but at all times that driving wheel receives the same amount of push or torque. Even if one wheel should be stationary while the other one is rotated—as when taking a very sharp corner—the push or torque to each wheel remains the same, because the two are connected through the medium of the differential gear, or balance gear as it may more correctly be termed, and, consequently, the turning effort which is applied to the rotating wheel is resisted by an equal and opposite force—the braking effort of the stationary wheel. The relative amount of movement of the two wheels, however, may differ very widely.

The operation of a differential gear, or balance gear, may best be understood if we imagine a man holding a rod by its center and parallel to the back axle, so that its two ends bear against the rear sides of two spokes—the top one in each of the two road wheels on the same axle. If he then pushes the rod forward and, assuming the axle and wheels to be free to move forward in a straight line only, he will transmit an equal amount of motion to each of the road wheels, but, if the axle and wheels are being steered round a corner, and, consequently, one of them requires to run faster than the other, the ends of the rod which acts as a beam will be rotated about the man's hand until they slide out of contact with the spokes of the road wheels. If we substitute for the simple rod a rimless star wheel, consisting of a hub and spokes only, the push of the man's hand may then be more or less continuously transmitted to the wheels, because, as one rod, or diametrically opposite pair of spokes in the star wheel, slides out of engagement with the spoke of the road wheels, another pair of spokes in the star wheel enter into engagement with others on the road wheels. This is practically what happens in the case of the differential gear. The star wheel is carried in a frame, which is driven round the center of the axle, and its spokes mesh with other spokes on the driving wheel.

Harking Back a Decade

TEN years ago a system of steam wagonettes made by the Mobile Company of America was put into service in New York City. The wagonettes plied between the Cortlandt and Wall street ferries and at the time the project was hailed with much acclaim as an improvement on one phase of New York's rapid transit. The enterprise has been so long forgotten that few residents even remember that it ever existed.

Experiments with motor-driven farm machinery and military wagons were being pursued.

The case of the original joy rider was noted when an employee of a Cleveland establishment used one of the firm's electric cars to give some of his lady friends a good time.

The idea of installing a carbureter for each cylinder was being gravely discussed.

The sporting section of motordom had its attention centered on the Newport Road race on the Ocean Drive. This race was later prohibited by the Rhode Island courts and was run off in Aquidneck Park, the winner turning up in W. K. Vanderbilt's Daimler, called the "Red Devil."

Ralph Estep wrote an essay on "Brazing Automobile Frames" in *The Motor Review* that reads like an account of modern practice.

Miles T. Baird and party motoring through the Yosemite valley found much hostility along the way.

GRAVITY FEED TANKS—In gravity feed work the gasoline tank must be located at least one foot above the float bowl of the carbureter, which condition is independent of every other consideration. In pressure feed work the gasoline tank is located below the deck of the body, and generally below the top of the chassis frame. Round or oval tanks are preferred; walls without curves bulge out unless they are braced by means of surge plates, of which two are used in most tanks. The tank generally conforms to the space provided by each type of chassis.

Stoddard-Dayton in Perspective

Six-Cylinder Knight Features the Line

In addition to several successful cars of the past season the Dayton Motor Car Co., of Dayton, Ohio, has incorporated in the forthcoming season's list of models a new car fitted with Silent Knight motor.

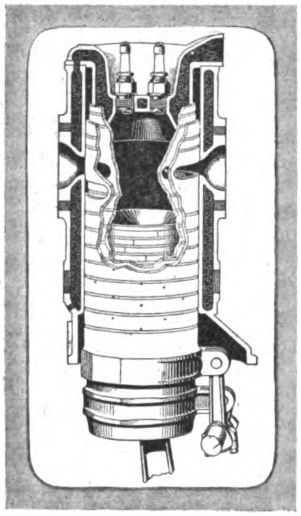

Fig. 1—Section through a cylinder of the Stoddard-Dayton Knight motor

THE Stoddard-Dayton-Knight as adopted by the Dayton Motor Car Co., has a motor fitted with six cylinders of 4 1-2-inch bore and 5 1-2-inch stroke. The general principle of the Knight motor is sufficiently familiar by this time, so that no useful purpose can be gained by going into the details of the motor. The sectional view shown in Fig. 1 gives a concise idea of the co-relation of the sliding sleeves at the moment of induction with the intake ports in register. The piston has a concave head, and the compression chamber being similarly formed, pocketing is entirely eliminated and the maximum effect of the explosion is thereby obtained.

It will be noticed that two spark plugs are fitted to each cylinder and it is possible, as will be shown later, to cause the spark to take place at both spark plug points practically simultaneously. The water jacketing, as can be seen from the illustration, is well taken care of, there being no protruding points likely to cause auto-ignition.

Although the piston has a stroke of 5 1-2 inches it is scarcely this so far as its friction is concerned because the sleeve moves down 1 1-8 inches. This facilitates lubrication and reduces wear on the side of the sleeve. On the compression stroke both inner and outer sleeves go up with the piston, the inner sleeve moving the faster. On the exhaust and induction strokes the sleeves move in an opposite direction to the piston; but on these strokes there is very little work being done by the piston and consequently there is a minimum of side thrust. The sleeves descend with the piston on the working or explosion stroke when the piston has the greatest amount of side thrust against the sleeve, thereby eliminating to a certain degree some of the thrust.

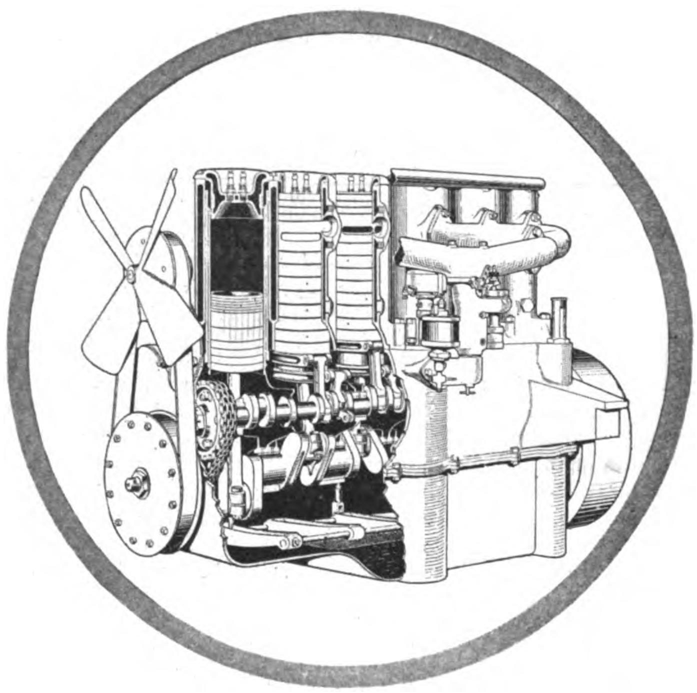

Fig. 3—Part sectional view of the Stoddard-Dayton six-cylinder Knight motor

The up-and-down movement of the sleeves is comparatively short. The piston stroke of 5 1-2 inches gives a piston speed of 916 feet per minute and 1,000 revolutions per minute of the motor. The stroke of each sleeve is 1 1-8 inches and its speed is but 93.7 feet per minute. This fact should be borne in mind by skeptics when endeavoring to solve the lubrication question as well as the wearing possibilities of this type of motor.

Fig. 3 shows a part sectional view of the Stoddard-Dayton Knight motor in which the eccentric shaft carrying the small eccentric rods is shown, driven by a silent chain from the crankshaft. Each cylinder has a separate port and the method in which the intake manifold is formed is clearly shown.

The crankshaft is of large diameter and runs in seven main bearings, which give a large bearing surface besides adding stability to the motor. In the upper half of the crankcase there are core ways

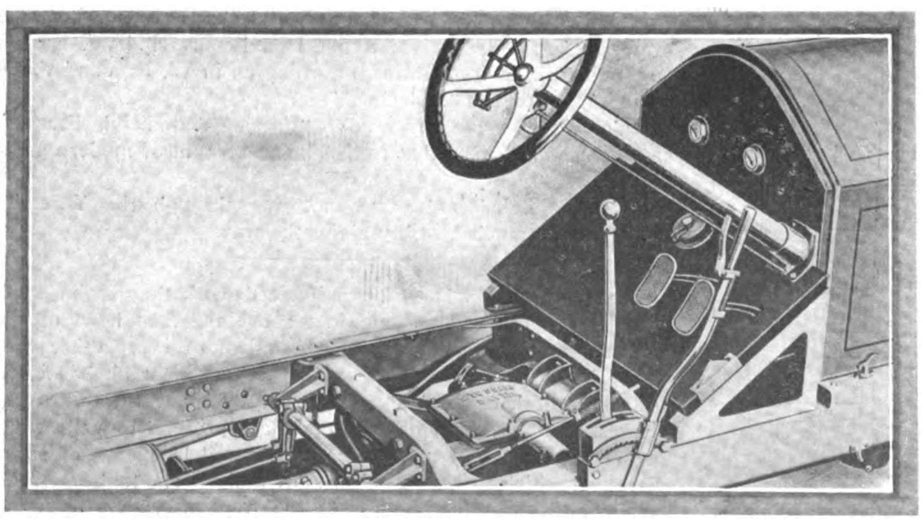

Fig. 2—Stoddard-Dayton chassis mid-section, showing control, clean dash and transmission

to which the air enters before reaching the carbureter. This serves two purposes, as the air is warmed passing through the base and the sound of inrushing air which prevents an otherwise quiet motor from performing silently is eliminated.

The lubrication of the Knight motor is effected by means of six troughs located transversely beneath the six connecting rods. The troughs are carried at one end on a boss shaft which is connected with the throttle. When the throttle is opened, which raises the troughs, the scoops on the ends of the connecting rods slip deep into the oil, thereby atomizing it and bathing the lower ends of the sleeves, whence the oil finds its way into the grooves cut in the sleeves shown in Fig. 1. The sleeves are drilled so that the oil can pass from one sleeve to the other. The troughs are kept replenished to overflowing by means of an oil pump situated at the base of the motor, and

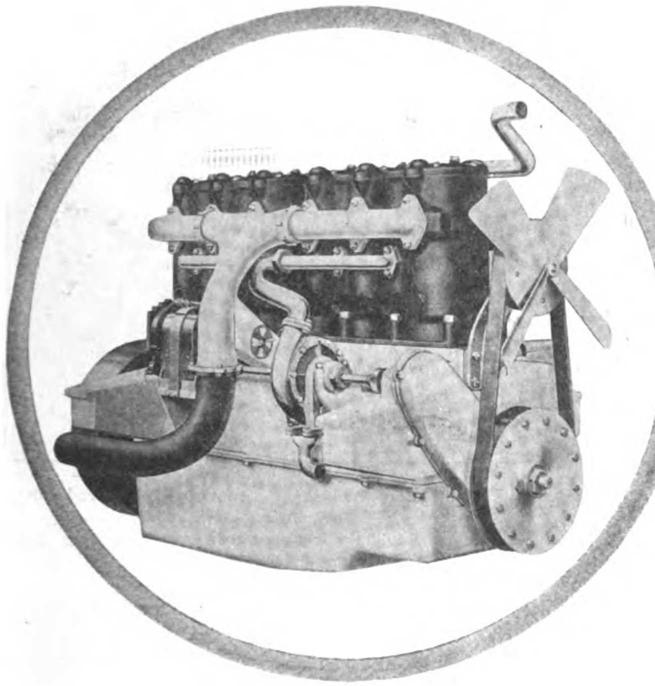

Fig. 4—Exhaust side of the 6-cylinder Stoddard-Dayton Knight motor, showing the water pump and magneto

by means of an adjustment it is possible to maintain the feed of oil to the speed requirements of the motor. A level gauge is fitted at the rear end of the motor to show the amount of oil in the sump.

Fig. 4 shows the right-hand side of the motor, disclosing the separate-ported exhaust manifold, the centrifugal water pump and the high-tension magneto, which are driven by means of a silent chain in a similar manner to the eccentric shaft. An air passage will be noticed partially surrounding the exhaust manifold, which conducts air through the cored passageway in the base chamber to the carbureter. A rotary shutter is provided so that the temperature of the air may be regulated and cold air admitted if found desirable. The front end of the crankshaft is extended through the base chamber and attached thereto with a pulley which drives a heavy 1 1-2-inch flat belt which in turn operates the four-bladed solid cast aluminum fan. The fan runs on annular ball bearings, carried in an eccentric collar so that adjustment of the tension of the belt can readily be made. The front of the crankshaft is equipped with a damper in order to overcome any tendency of uneven running of the motor at high engine speeds.

The ignition is furnished to the spark plugs from a two-spark high-tension ignition system controlled by the one switch and coil on either magneto or battery through two sets of plugs. The carbureter is of the constant-level automatic type, the mixing chamber of which is heated by a circulation of warm water. The auxiliary air valve is provided with an adjustment controlled by a short lever on the steering post, which allows variations to be made while the car is running, thereby placing at the driver's disposal a ready and certain means to meet the daily variations in temperature, humidity, and so on.

Fig. 8 shows the Stoddard-Dayton valve-in-the-head motor, the salient external features of which are apparent from the illustration. Heretofore the expulsion of exploded gases has been dependent in a large measure upon the movement of the piston, but as the compression chamber cannot be entirely scavenged by the piston a certain residue of the burnt gases always remains behind which intermingles with the fresh gases that are taken in on the induction stroke. In order to overcome this a multiple manifold is provided, and within the outer exhaust manifold are various pipes and chambers so designed that when one cylinder is exhausting the action forms a suction in the pipe of the next cylinder to be exhausted. The right-hand side of the valve-in-the-head motor can be seen by referring to Fig. 10 Independent camshafts are provided for the inlet and exhaust valves and the method of operating the valves can be seen in the illustration.

In order to differentiate between the various models manufactured by this concern names have been chosen for the different types of chassis instead of letters. The "Special" is a 58-horsepower chassis, four-cylinder, 5-inch bore by 5 1-2-inch stroke, and has a wheelbase of 130 inches for the touring and limousine bodies and 122 1-2-inch wheelbase for the four-passenger torpedo and two-seated roadster. The "Saybrook" model has a motor of 48 horsepower, the bore 4 3-4 with 5-inch stroke and a wheelbase of 122 1-2 inches. The "Stratford" model is fitted with a 38-horsepower motor with L-head motor, the cylinders being 4 1-8-inch bore and the stroke 5 1-4 inches. the wheelbase of the chassis being 114 inches. The "Savoy" model is fitted with an L-head motor, the cylinders of which are 4-inch bore and 4 1-2-inch stroke, with 112-inch wheelbase. The smallest model manufactured is the "Courier" chassis, with a 30-horsepower motor, 3 3-4 inches bore and 5 1-8-inch stroke. the wheelbase of the chassis being 106 inches. The various chassis are fitted with an exceptionally complete line of body work, a few examples of which are shown in the accompanying illustrations. The chassis particulars of the "Knight," "Special," and "Saybrook" models are identical. The clutch fitted to Stoddard-Dayton cars on these models is of the leather-faced cone type, the cone being of cast aluminum faced with leather

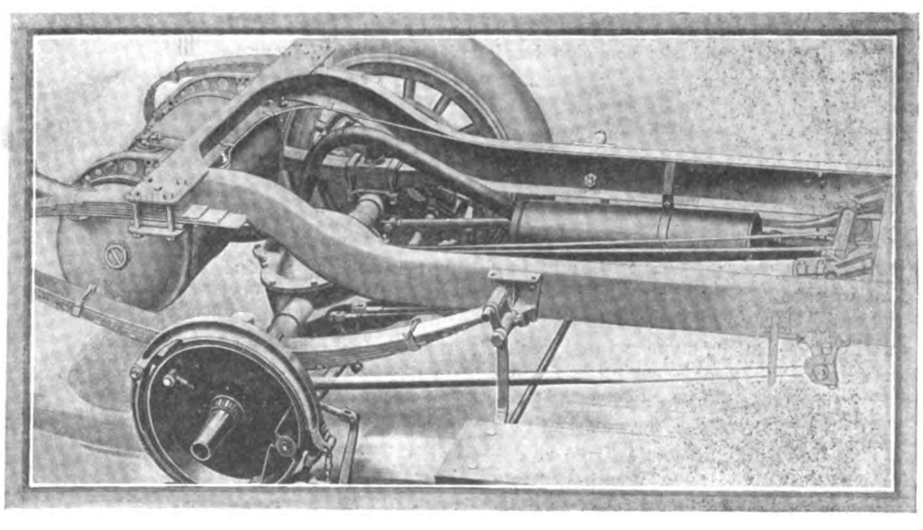

Fig. 5—Rear construction of the Stoddard-Dayton "Special," showing the elliptic springs and frame

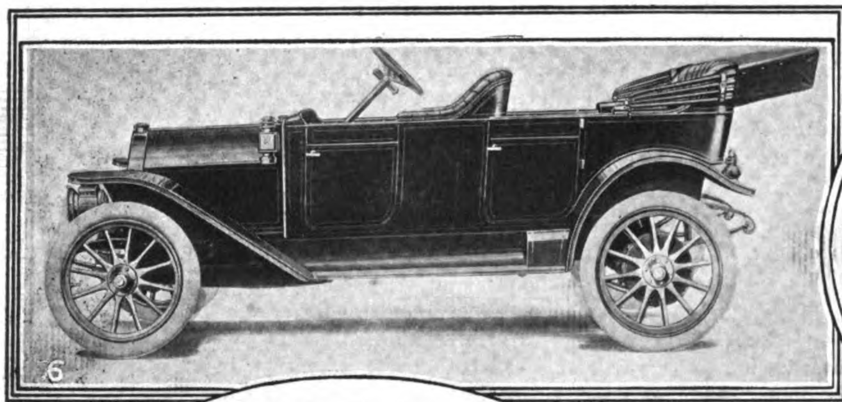

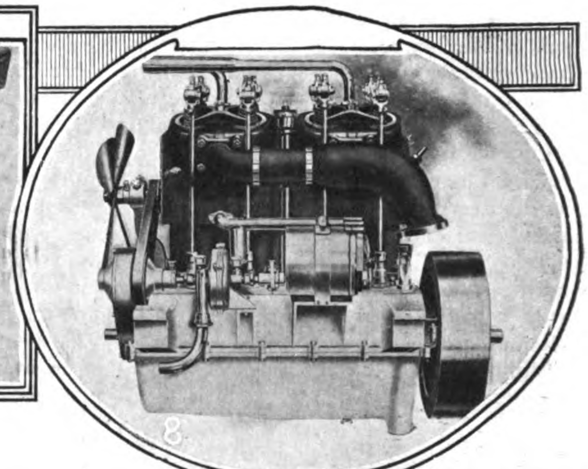

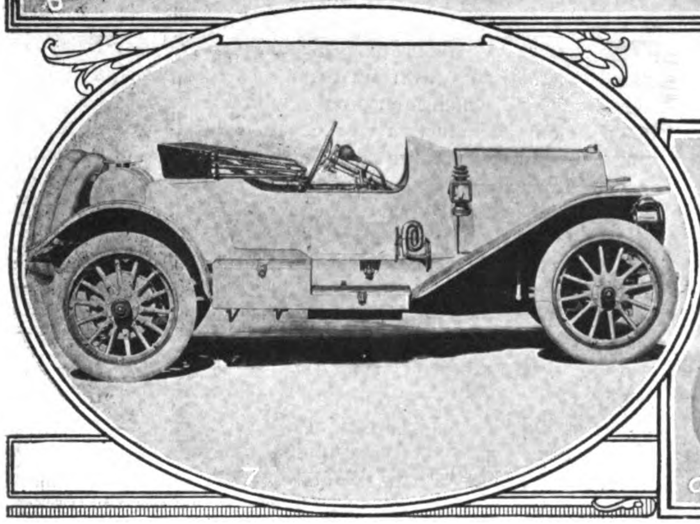

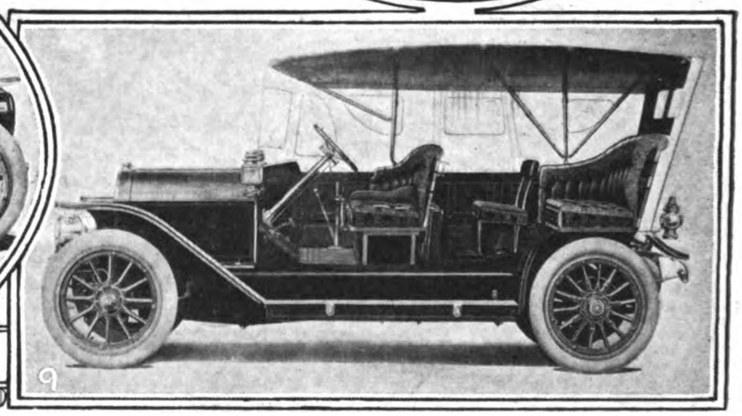

Fig. 6—General appearance of the Stoddard-Dayton "Savoy" type of touring car

Fig. 7—Stoddard-Dayton compartment torpedo with dust and waterproof luggage compartment

Fig. 8—Exhaust side of the Stoddard-Dayton valve-in-the-head motor, showing the multiple exhaust manifold

Fig. 9—Side view of a Stoddard-Dayton touring car, showing roominess for the occupants of all seats

and backed by a large number of flat flexible springs to cause the leather to raise in spots, thereby giving a gradual operation and eliminating shocks to the transmission through careless engagement. Ball bearing thrusts are used inside and out and the clutch spring is self-contained, eliminating end thrusts on the crankshaft while the motor is running. A general idea of the appearance of the transmission gear, shift lever, pedals and control is given in Fig. 2. The transmission is of the selective type, giving three speeds forward and one reverse, the shafts being carried upon double annular ball bearings; steam type packing glands are employed, which permit the use of a thin lubricant without the fear of leakage through the bearing housings. Between the clutch and transmission there is a double sliding universal joint, the casing of which is drop forged and hardened and the blocks are also hardened to eliminate wear.

Fig. 5 shows the general arrangement of the live rear axle, brake mechanisms and torque rods. The propeller shaft connecting the transmission to the bevel gearing is fitted with a universal joint at the forward extremity and is supported by a torsion tube which is held in its front end in a bolt joint allowing sliding motion fore and aft in addition to its universal movement. Radii rods are fitted at each end with universal joints, thus doing away with any binding or cramping action that would impede their proper functioning or cause undue wear and rattling. The axle of the three above-mentioned models is of the full-floating type with jackshafts turned from chrome nickel steel. The axle casing is fitted with a cover which when removed gives complete access to the working parts and permits the differential to be removed readily.

The front axle is made from a cold drawn bar of what is known as "Plow-Beam" section, having reinforcements at the corners to guard against the twisting strains to which front axles are subjected.

Shock absorbers are regular equipment of the "Knight," "Special" and "Seabrook" models. Two sets of brakes are provided, operating upon the drums attached to the rear wheels and forming part of the hub flange. The drums are 14 inches in diameter on the "Saybrook" model and 16 inches in diameter on the "Special" and "Knight" models. The external brake has a two-part, forged steel, I-shaped band 2 1-2 inches wide, hinged and

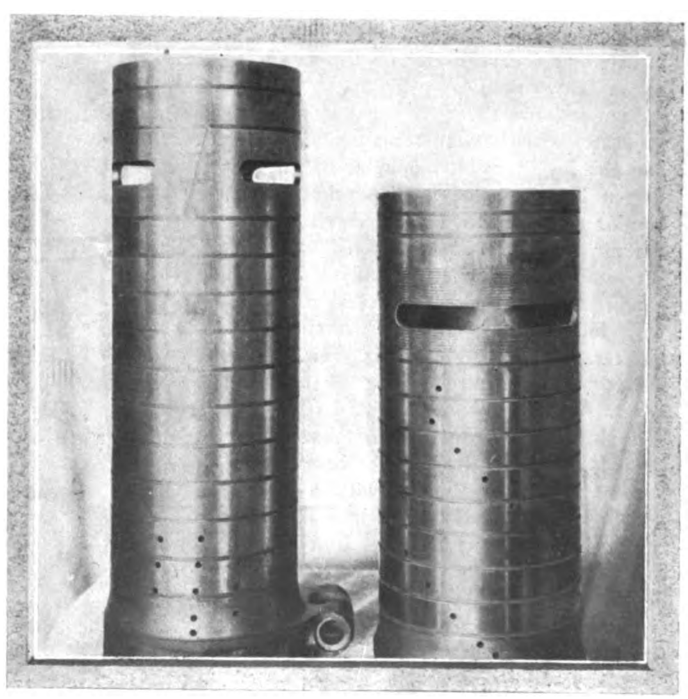

Fig. 14—General view of the inner and outer sleeve, showing method of slotting and diagonal drilling for lubrication

Fig. 11—Stoddard-Dayton "Stratford" three-passenger coupé

Fig. 12—Flush sided seven-passenger body, fitted to a Stoddard-Dayton-Knight chassis

Fig. 13—Interior view of Stoddard-Dayton compartment torpedo, showing accessibility of luggage space

faced with raybestos. All connecting rods are now placed on the inner side of the frame and the brake adjustment is made by means of turn buckles, which are easily accessible, as they lay directly beneath front floor boards. The suspension of the car is taken care of by 3-4 elliptic springs at the rear and semi-elliptic springs at the forward end, the leaves being 2 1-2 inches in width. The spring bolts have large diameters and are fitted with grease cups. The frame is on the pressed steel type of U section, pressed cold from a medium carbon steel, the stock being 3-16 of an inch with 2 1-4 inch flanges. In order to eliminate body squeaks and vibration the bodies are set on rubber bumpers in the frame.

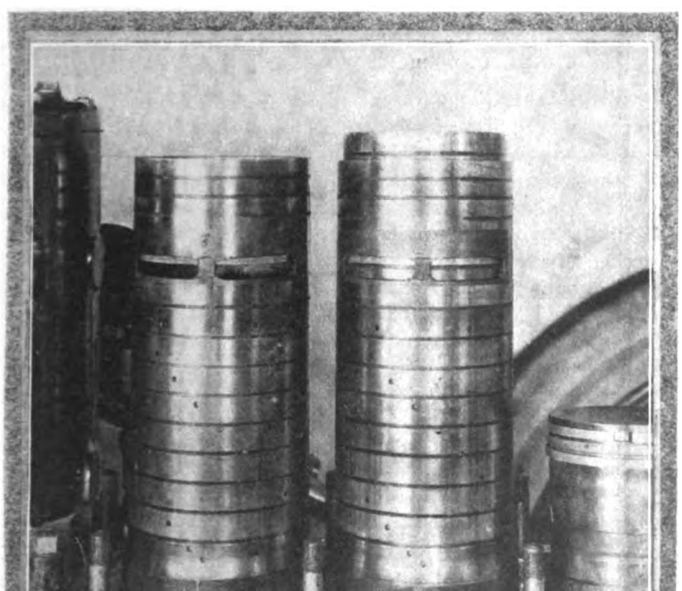

Fig. 15—Appearance of sleeves of Stoddard-Dayton-Knight motor, exhaust side, after having run three thousand miles

The radiator is of the cellular type, with distributing manifold for spreading the water to the sides as well as to the center of the cooling core.

In the three models under notice the front seats are entirely separate from the body and are adjustable forward and back, giving drivers of various leg lengths a means of adjustment. The 2-passenger car shown in the illustration, in which the compartment is of sufficient size to carry two suit cases, is a distinct innovation.

Stoddard-Dayton at Close Quarters

The staff man of THE AUTOMOBILE had an opportunity, thanks to the courtesy of the manager of the New York branch of the Dayton Motor Car Company, of inspecting the first six-cylinder Knight motor that had been manufactured in America.

The front block of cylinders was dismantled, which gave an opportunity of inspecting the various working parts after the car had run a matter of 3,000 miles. The photographs of the parts shown in Figs. 14 to 19 show the state of the motor better than words can express it. It was not expected that any wear would take place in so short a distance, but what it did show was that a perfect film of oil is maintained between the various surfaces and that discoloration of the ports was a negligible quantity.

It may be mentioned incidentally that the Stoddard-Dayton

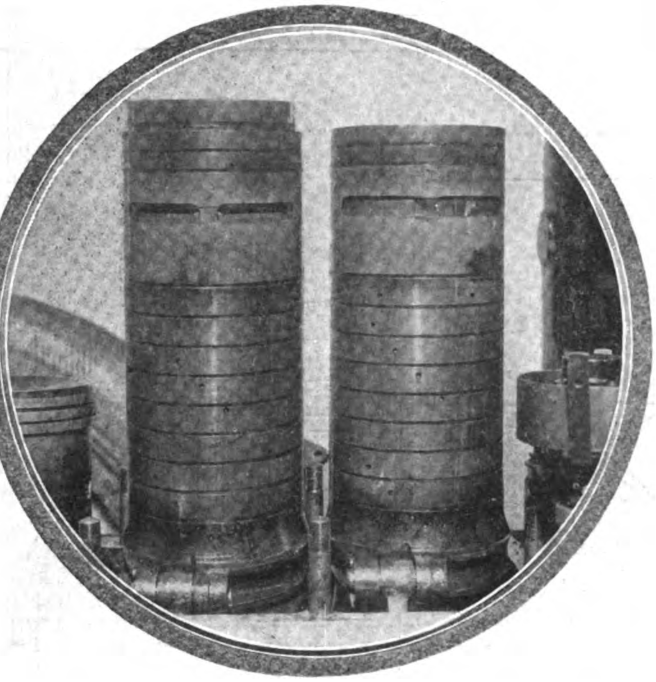

Fig. 16—Appearance of the sleeves of the Stoddard-Dayton-Knight motor, intake side, after having run three thousand miles

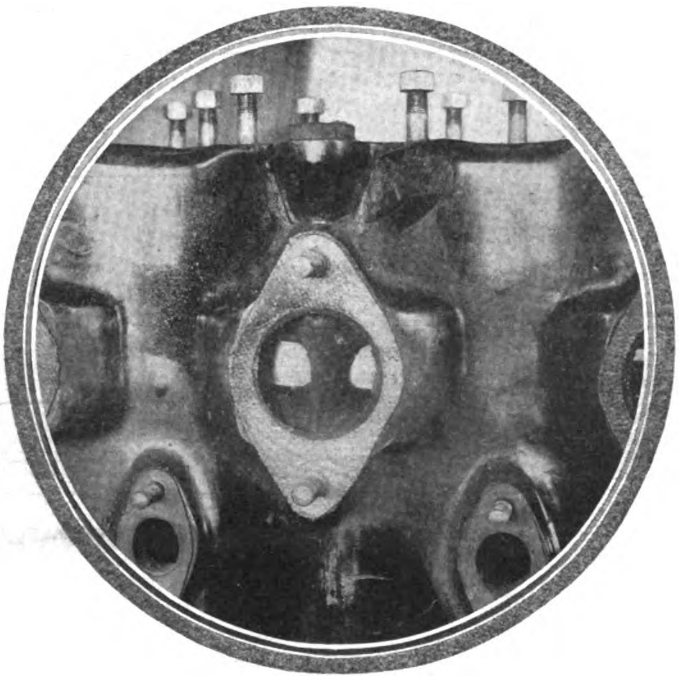

Fig. 18—Exhaust side of Stoddard-Dayton-Knight motor, showing central web in the passage-way forming a support for connecting piece in sleeve

Knight motor is the longest stroke motor of this type that has so far been manufactured by any of the companies who build motors under the Knight patents. Fig. 14 shows a general view of the inner and outer sleeves. The method of ringing the sleeves in the form of circular grooves can be seen so that the lubrication will be properly taken care of and prevent an excess of oil being carried up into the combustion chamber. Each of the sleeves has been drilled to permit the lubricant to freely circulate, and as the outer sleeve is the longer of the pair this has been drilled with holes set diagonally to the axis of the piston in the manner shown in the illustration. Another feature of the sleeves can be seen in the vicinity of the longer or outer sleeve port. Small slots are cut radially above and below the port which in time collect a certain amount of the carbon deposit and tend to keep the cylinder port free from any foreign matter.

A slight idea of this can be seen by referring to Fig. 15, which shows two of the sleeves on the exhaust side of the motor after the cylinders had been removed. Again, referring to Fig. 16, the appearance of the sleeves on the intake side shows an absolutely clean surface, the polish left by the grinding machine being still discernible. The valve timing of this motor is particularly worthy of notice as it varies from previous Knight practice. The intake valve opens on top dead center and closes 40 degrees after lower dead center, while the exhaust valve opens 50 degrees before lower dead center and closes 12 degrees after top dead center, which allows a lapping of the two valves of 12 degrees.

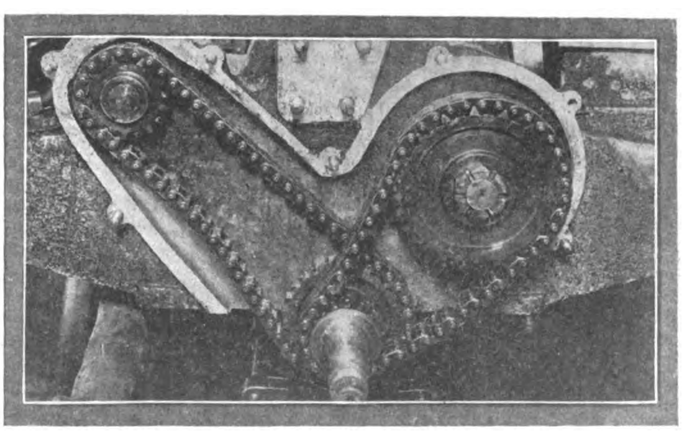

Fig. 19—Silent-chain drive employed on the Stoddard-Dayton-Knight motor

The external appearance of the cylinders of the motor, which are cast in two blocks of three each, do not adequately show the size of the ports; but there is a considerable difference in the shape of the intake and exhaust ports. Fig. 17 shows the intake ports, which consist of a straight slot, circular in form, which cannot be shown in a photograph as the casting at this point tapers outward, allowing the slot in the cylinder to register the same size as the slots in the sleeves. It will be noticed in Fig. 15 that there is a slight rib placed in the middle of the slots, which registers with the web in the port shown in Fig. 18. This rib is of lesser diameter than the sleeve and consequently does not rub either against the piston or the cylinder wall. The width of the slot is 9-16 of an inch, which has been found the best working dimensions for this size of motor. In order to overcome the inconveniences that sometimes attend the proportionate flow of gas from the carbureter to the cylinders the induction manifold has been cast with internal baffle-plates, thereby distributing the gases evenly to the separate ports.

A point that was first of all extensively adopted in the Knight motor is shown in Fig. 19. In this illustration the method of driving the eccentric, pump and magneto shafts is shown. Two sprocket wheels are attached to the extension of the crankshaft and the two silent chains drive the sprocket wheels that are attached respectively to the eccentric and pump shafts. These chains run continually in a bath of oil and besides being silent in operation, should offer very little wearing possibilities.

Left-hand driving has been incorporated in the Knight Stoddard-Dayton car and the change speed and brake levers are located on the right hand side of the driver. The electric lighting system, that is a regular feature on this car, is driven by a silent chain from the shaft that is situated between the clutch and the transmission. By removing the floor boards immediate access is obtained to this part of the equipment and its location leaves the motor surroundings entirely free. The piston rings of this motor differ from conventional practice; the grooves in the piston and cylinder head are fitted with two independent rings, the inner one being slightly eccentric, while the outer is cylindrical. Besides the general features already outlined, several minor improvements are worthy of notice. A neat arrangement is provided for altering the timing of the magneto without disturbing the distribution gear. The water piping and tubing that carry the ignition wires are neatly executed and removable by simply loosening the nuts instead of having to take them off entirely. Pressure for the gasoline tank is derived from a small pump driven by a short arm off the eccentric shaft, in which case only atmospheric air is employed and filtration eliminated.

Program for Old Orchard Meet

OLD ORCHARD, ME., Aug. 21—W. T. Kincaid, who is promoting the motor races on Old Orchard beach for next month beginning Labor day, has mapped out a program covering three days' racing. There are 17 events on the list divided up according to the A. A. A. rules. The first two days have six each with five on the third day. Cash prizes will be given in the greater number of the events, there being one amateur contest scheduled. The list of events follow:

FIRST DAY, SEPTEMBER 4.

Event 1, Class C—Non-stock, 161 to 230, 5 miles, entry fee $10, prize $50.
2, Class B—Stock chassis, 231 to 300, 10 miles, entry fee $10, prize $50.
3, Class D—Free-for-all one-mile time trials, no entry fee, prize $50.
4, Class B—Stock chassis, 451 to 600, 10 miles, entry fee $10, prize $50.
5. Class E—Special amateur event, 5 miles, open to any car privately owned, owner to drive, entry fee $5, prize trophy.
6, Class D—Free for all, 10 miles, entry fee $15, prize $100.

SECOND DAY, SEPTEMBER 5.

Event 1, Class B—Stock chassis, 161 to 230, 5 miles, entry fee $10, prize $50.
2, Class C—Non-stock, 451 to 600, 10 miles, entry fee $10, prize $50.
3, Class D—Free-for-all, one-mile time trials, no entry fee, prize $50.
4, Class B—Stock chassis, 301 to 450, 10 miles, entry fee $10, prize $50.
5, Class C—Non-stock, 231 to 300, 5 miles, entry fee $10, prize $50.
6, Class D—Free for all, 10 miles, entry fee $15, prize $100.

THIRD DAY, SEPTEMBER 6.

Event 1, Class E—Stock chassis under 301 cubic inches, 5 miles, entry fee $10, prize $50.

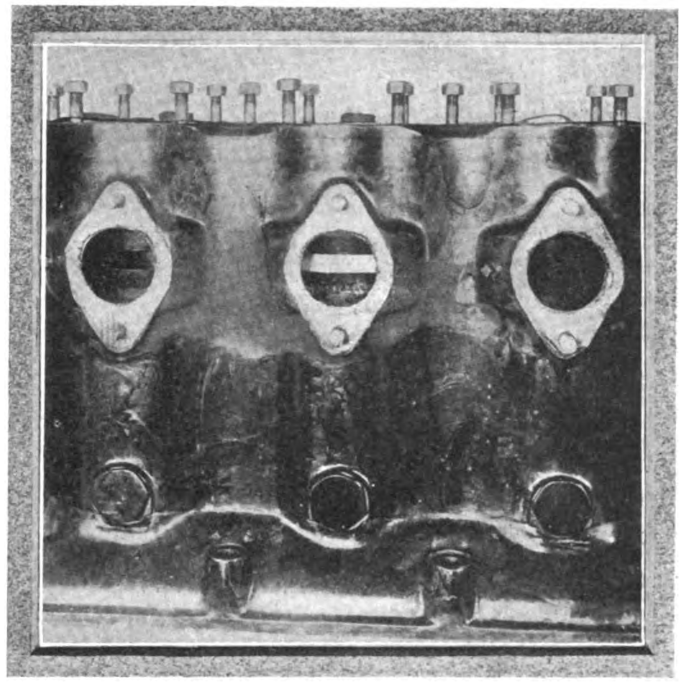

Fig. 17—General appearance of the three-block cylinder, showing the intake ports with the manifold and cylinder heads removed

2, Class E—Stock chassis, 301 to 600 cubic inches, 10 miles, entry fee $10, prize $50.
3, Class D—Free-for-all one-mile time trials, no entry fee, prize $50
4, Class D—Free for all, 10 miles, entry fee $15, prize $100.
5, Class E—Non-stock under 600 cubic inches, 25 miles, entry fee $20, prizes $100 to first and $25 to second.

Calendar of Coming Events

Handy List of Future Competitive and Show Fixtures

Shows

Jan. 1-5, 1912......New York City, Grand Central Palace, Annual Show, Automobile Manufacturers' Association of America.
Jan. 6-13...........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 10-17..........New York City, Madison Square Garden, Annual Show, Motor and Accessories Manufacturers.
Jan. 10-17..........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers.
Jan. 15-20..........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers.

Race Meets, Runs, Hill-Climbs, Etc.

Aug. 25-26.........Elgin, Ill., Stock Chassis Road Race, Chicago Motor Club.
Sept. 1............Oklahoma, Reliability Run, *Daily Oklahoman*.
Sept. 2............Pottstown, Pa., Track Races, South Jersey Motor Club.
Sept. 2............Scranton, Pa., Track Races, Automobile Association of Scranton.
Sept. 2, 3, 4.......Kansas City, Mo., Track Races, Automobile Club of Kansas City.
Sept. 2-4..........Amarillo, Tex., Track Races, Panhandle Auto Fair Association.
Sept. 2-4..........Brighton Beach, N. Y., Track Races.
Sept. 3............Columbus, O., 200-mile Race, Columbus Automobile Club.
Sept. 4............Denver, Col., Track Races, Denver Motor Club.
Sept. 4............Salem, N. J., Track Races, South Jersey Motor Club.
Sept. 4, 5, 6.......Old Orchard, Me., Beach Races, Old Orchard Automobile Association.
Sept. 6-9..........Buffalo, N. Y., Grade I, Reliability Run, Automobile Club of Buffalo.
Sept. 7-8..........Philadelphia, Track Races, Philadelphia Auto Trade Association.
Sept. 8-9..........Hamline, Minn., Track Races, Minnesota State Automobile Association.
Sept. 9............Augusta, Me., Hill Climb.
Sept. 9............Cincinnati, O., Road Race, Fern Bank Dam Association.
Sept. 9............Hartford, Conn., Track Races, Connecticut Fair Association.
Sept. 9............Port Jefferson, L. I., Hill Climb, Port Jefferson Automobile Club.
Sept. 9............Riverhead, L. I., Road Race, Port Jefferson Automobile Club.
Sept. 13...........Grand Rapids, Mich., Track Races, Michigan State Auto Association.
Sept. 15...........Knoxville, Tenn., Track Races, Appalachian Exposition.
Sept. 16...........Philadelphia (Point Breeze), Track Races, Philadelphia Automobile Trade Association.
Sept. 16...........Syracuse, N. Y., Track Races, Automobile Club and Dealers.
Sept. 18-20........Chicago, Ill., Commercial Reliability Run, Chicago Motor Club.
Sept. 19...........Burlington, Vt., Reliability Run, Merchants' Protective Association.
Sept. 23-25........Detroit, Mich., Track Races, Michigan State Agricultural Society.
Sept. ....Denver, Col., Track Races, Denver Motor Club.
Sept. ....Detroit, Mich., Reliability Run, Wolverine Automobile Club.
Sept. ....Steubenville, O., Hill Climb, Automobile Club of Jefferson County.
Oct. 6-13..........Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 7.............Danbury, Conn., Track Races, Danbury Agricultural Society.
Oct. 7.............Philadelphia, Fairmount Park Road Races, Quaker City Motor Club.
Oct. 7.............Springfield, Ill., Track Races, Springfield Automobile Club.
Oct. 13-14.........Atlanta, Ga., Track Races.
Oct. 14............Santa Monica, Cal., Road Races.
Oct. 14 to 25......New York City, Start of the Annual Glidden Tour, en route for Jacksonville, Fla.
Oct. 16-18.........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.
Nov. 1.............Waco, Tex., Track Races, Waco Auto Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 4-6...........Los Angeles,-Phoenix Road Race, Maricopa Auto Club.
Nov. 9.............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9, 11, 12.....San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27............Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30............Los Angeles, Cal., Track Races, Motordrome.
Nov. 30............Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Nov. ....Columbia, S. C., Track Races, Automobile Club of Columbia.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.

CLEAN UP NEW YORK STATE

SEPTEMBER 1 has been selected as housecleaning day for the State of New York. On that date the new law, making it a misdemeanor to post bills on trees, stumps, posts. fences, stones and hundreds of other places without the permission of the property owner, goes into effect. On the same day it has been suggested that everybody interested in the future welfare of the Empire State use his or her influence for the general improvement of the appearance of the countryside, the small villages, the towns and even the cities.

Housecleaning New York State is not any child's play. In some places trees have been covered from the roots as high up the trunk as the energetic bill poster has been able to reach; every old building near the highway has been converted into a crazy-quilt advertising sign; every corner fence has been covered.

To remove all this débris will require energy; it will require co-operation, and it will require organization. Spasmodic mixtures of printers' ink disfiguring a beautiful landscape do not add to the joy of the automobilists outing, and now that the State has taken the matter in hand it is up to the automobile owners to get together and help the good work along.

The best way for the automobilists is to get busy at once. September 1 will be pretty late. Get the enthusiasm, at least, worked up before that date. The New York State Association should take the lead. To every one of its affiliated clubs should go out a letter advising them of the housecleaning program and requiring them to organize at once a housecleaning committee. Where clubs do not exist the enthusiasm must be stirred up and transferred into action. This can be done by communicating with the leading automobile people in such sections through the press.

With the citizens of our State this work should be looked upon as an investment and not an expense. The cleaning up of the State will advertise it from one ocean to the other; the cleaning up of the State will increase the pride that every resident should have in his State; this cleaning up will bring tourists to our valleys, our lakes and our mountain sections who have never been to them before.

September 1 brings into force one other good law in New York State, namely, protection to roadside signs which have for their object warning on steep hills, warning for sharp and dangerous curves, warning for dangerous railroad crossings, as well as ordinary direction signs to towns and cities. For years there has been much malicious destruction of sign boards erected by the many enterprising clubs throughout New York and other States. To date there has been little hope of hunting down the offenders. The new law provides for this and when enforced will mean thousands of dollars per year to motoring organizations as well as great pleasure to the automobiling public.

* * *

BACKWARD, TURN BACKWARD

QUITE a few car owners would to-day like to go backward to the conditions of five or six years ago, rather than exert themselves enough to keep pace with the march of progress in the automobile field. There are scores of car owners who would like to have the old single-cylinder motors instead of the four or the six; there are others who would gladly cast the magneto aside, supplanting it with the dry cells; others ask for the planetary gearset instead of the selective, and many requests of similar tone are heard nearly every week.

These expressions come from a general atmosphere of uncertainty. It pervades so many sections of the industry. It is due to the evolutionary period through which we are passing. We have not reached the goal in any particular department of the motor car. The pneumatic tire is a marvel, but there are scores who are looking forward to the invention and manufacture of some Utopian spring wheel or cushion tire that will give satisfactory results at much lower cost. Hundreds are convinced that the ideal in carburetion is yet far off; and, in fact, carbureter makers are experimenting with the venturi, the multiple nozzle, waterjacketing and a score of other things. Nobody is certain to-day whether the poppet valve is going to remain in the ascendency for five years or if the slide-valve motor will usurp its position, or if some form of rotary valve will win out. In the contest department the experts are puzzled whether stock car events or free-for-all races will be the leader in a couple of years. Some makers are wondering whether it is better to go into races, reliability runs or other forms of tests. No wonder buyers wish for Father Time to turn back the hands. All this unrest is characteristic of the age; it pervades many other industries to-day, it is indicative of progress. Were we all contented, were everything to our liking, we would be miserable; in fact, we would be through with our usefulness in this world.

Detroit to Hold Season's First Show

Big Exhibition at Michigan State Fair

Full 1912 lines of automobiles, both commercial and pleasure, have been entered for space at the annual exposition, which will be held this year from Sept. 18 to 22. Manufacturing situation is far more favorable this Summer than it was last year and some of the companies are still under high pressure. Poss Company occupies deserted Anhut factory and intends to put out 1200 cars for 1912. The Detroit Automobile Dealers' Association will exhibit during the week of January 22.

DETROIT, Aug. 21—Detroit motordom is looking forward with great interest to what is likely to be the first comprehensive display of 1912 motor cars to be held anywhere in the United States. Reference is, of course, made to the annual show which takes place in the building particularly constructed for the purpose, on the grounds of the Michigan State Fair. Of course, the dates are coincident with those of the fair, September 18-22.

Every foot of space in "Motor Hall" has been taken and the larger number of the Detroit factories will exhibit, either directly or through their Michigan distributors. In addition, most of the manufacturers of motor cars whose factories are in Michigan, though outside Detroit, will be on hand.

Among the exhibitors will be representatives of the Jackson, Cole, Studebaker Corporation, Rapid, Brush, Poss, Hupmobile, Detroit Motor Wagon Co., Chalmers, Commerce Motor Car Co., Elmore, Hudson, Day Utility, Lion, General Motors, Abbott-Detroit, Cartercar, Regal, Oakland, Everitt, Cadillac, Buick, Overland, Detroit Electric, United Motors, Seitz, Mitchell-Lewis and many others. In each case the exhibitors promise to make displays of the complete lines for the coming year. In many cases the cars will be shown for the first time.

The fair's automobile show has come to be one of its most attractive features. In addition to the motor-wise who come to get their first view at the new designs, there is a large attendance of prospective purchasers who come to make their choice at a place where they have free access to the latest types.

The show has a separate management which, though under the general control of the Fair association, acts independently in conducting the display. Walter Wilmot is the show manager.

Following the sale of his Hupmobile stock by R. C. Hupp, the Hupp Motor Co. has issued the following announcement:

Charles D. Hastings has been appointed general manager of the Hupp Motor Car Co., to succeed R. C. Hupp, who has resigned, to devote his entire attention to other interests. Mr. Hastings has been with the Hupp Motor Car Co. as assistant general manager since its inception and has always been prominently identified in the executive affairs of this company, so that the retirement of Mr. Hupp will in no way affect the plans or policy of the Hupp Motor Car Co.

Mr. Hastings has been identified with the automobile industry since its infancy, having been connected with the Olds Motor Car Co. before the Hupmobile came into the market.

E. A. Nelson, the designer and chief engineer of the Hupp Motor Car Co., to whom is due the credit of the design and motor of the Hupmobile, is at the head of the engineering department of the factory, and the personnel of the officials of the company remains unchanged with the exception of Mr. Hupp's retirement.

The Hupp Motor Car Co. is interested only in the manufacture of the Hupmobile and has no other connection.

Production of 1912 models is in progress at all plants in Detroit at present and, while the rush of getting out demonstrators for the dealers is now over and there is very little night work, general activity is in progress to a much more noticeable extent than a year ago. The Packard is steadily increasing its force and is working at a rate in excess of anything in its history. The firm will shortly come into the possession of additional floor space which will raise its producing area to 37 acres. At present the plant employs 7,000 men and is the largest purchaser of labor in the local field. The firm is now about two weeks behind orders and is working its machine shop at night.

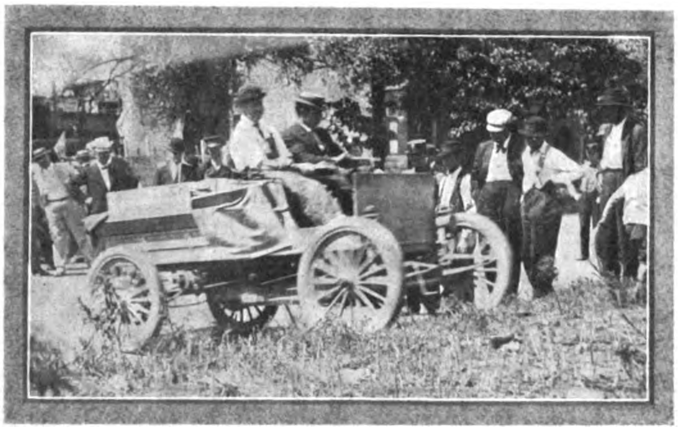
The deserted plant where the Anhut Six was formerly made has been occupied during the past week by the Poss Motor Co., the first car of which participated in the recent *Evening American* run between Detroit and Chicago. It is announced that the concern will produce 1,200 light delivery trucks during the coming year, with a load capacity of from 1,200 to 1,500 pounds.

The Poss is one of the few new concerns to enter the lists this season and, like nearly all of its generation, is a producer of commercial, rather than pleasure, vehicles. A number of new manufacturing concerns have been recently formed to produce parts and equipment, however. Among these are the Auto Lock & Specialty Co., of Detroit, capitalized at $15,000; the Durable Top Specialty Co., of Detroit, $15,000; and the Mason Motor Co., of Flint, $100,000.

The week of January 22 has been selected as the date for the annual show of the Detroit Automobile Dealers' Association. Though no formal announcement has been made, it is probable that the show will again be held in the inadequate Wayne Gardens. This condition last year led to a secession of representatives of forty-five manufacturers who held a separate and competing show at the factory of the Regal Co. In all probability, those crowded out of the Gardens will take some similar action this year, as their show was a great success.

S. A. E. Adopts Standard Tires

Realizing the advantages to be gained by bringing about a condition of interchangeability between different makes of solid tires the Society of Automobile Engineers has, after considerable investigation, adopted a table of standard tire and wheel dimensions. It was universally acknowledged that it was of mutual advantage to all parties concerned that such a condition of standardization should obtain, but there was considerable work involved in order to determine what the various dimensions should be. The report was finally made, however, last Spring, and the plans of the motor vehicle manufacturers are to put the standards into effect by the beginning of the next calendar year.



Lincoln, No. 24, winner Class 2K, undergoing brake test

Le Moon, No. 23, winner in Class 4K, checked in first at South Bend

Chicago Truck Run Finished

Six Perfect on Road with Buick as Winner

Of the twenty-six starters in the truck run under the auspices of the Chicago "American," which lasted nine days and was laid out through rough going for two days, twenty-four checked in on time. The cars covered Indiana, Ohio and Michigan and ran on a schedulee of from eight to fourteen miles an hour. Despite adverse road conditions the column made a fine showing.

CHICAGO, Aug. 21—On August 17, the nine-day reliability run for commercial vehicles, promoted by the Chicago *Evening American*, ended at the starting point, in Chicago. The route was from Chicago to Detroit, with night stops at South Bend, Fort Wayne, Lima and Toledo; and back by way of Jackson, Kalamazoo and South Bend. The distance covered was 756 miles, with the vehicles runing at an average schedule speed of from 8 to 14 miles per hour.

Of the twenty-six vehicles that started in the run, twenty-five finished and twenty-four checked in on time, only one having fallen out on the fourth day as a result of engine trouble. Six out of the twenty-five to finish had perfect scores at the end of the run; but only one of these managed to survive the final technical examinations.

A two-cylinder Buick delivery wagon, with a load of 1500 pounds and driven by F. W. Kunze, was the only perfect score

Group of drivers who participated in the Chicago American's truck run—taken at Jackson, Mich.

car at the end of the final technical examinations. The six cars, however, that managed to finish with perfect road scores included two Buicks, Hewitt, Nelson-LeMoon, Federal and Mais.

All of the above cars, however, are not winners. In deciding the winner of the tour the cost of operation per ton-mile has been the chief determining factor, while the road penalties and those of the final technical examination have been a minor consideration; it will be found, however, in some instances that the latter assumed the greater proportions in the final score.

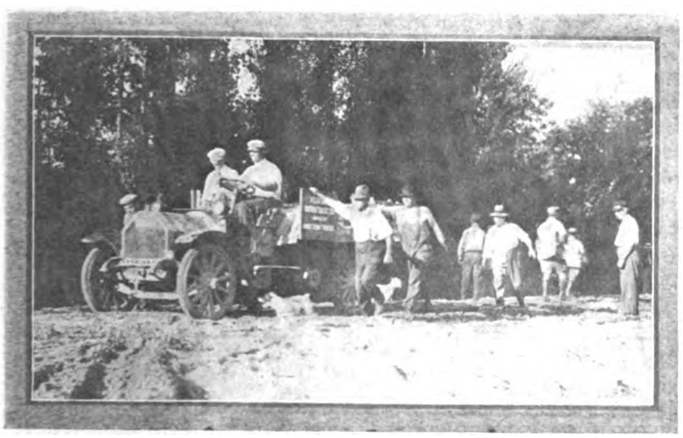
As shown in an accompanying table, the cup winners in the respective classes are as follows: Class 2K, No. 24 Lincoln; Class 3K, No. 10 Buick; Class 4K, No. 23, Nelson-LeMoon; Class 5K, No. 32 Federal; Class 6K, No. 2 Gramm; Class 7K, No. 13 Mais; Class 8K, No. 17 Kelly; and Class 9K, No. 4 Gramm.

In promoting this contest, it has been the object of the Chicago *Evening American* not only to emphasize the superiority of the motor over the horse-drawn vehicle, but also to demonstrate to the purchaser of commercial vehicles the cost of their operation. An accurate record of all the gasoline and oil used by each vehicle throughout the run has been kept by the technical committee, as well as an account of all repairs and adjustments made; and these factors, together with a certain stipulated sum or percentage for tire cost per mile, up-keep cost, and chassis depreciation per annum, have been used to determine the winner of the contest.

In the data collected during this demonstration there is much, perhaps, that is not to be taken too seriously, because the constants or percentages used to decide the winners are of an arbitrary nature. As yet there is no data on which an absolutely fair percentage of chassis depreciation and tire cost can be based; nor can the reliability of a commercial vehicle be fairly demonstrated in a run of but 756, 1000, or even 2000 miles. Depreciation hardly begins until a vehicle has been run 2000 miles, and then it is not in direct proportion to the mileage, but in an ever-increasing ratio. This ratio, too, is affected to a very great extent by the character of the tires employed.

In this demonstration each of the vehicles was loaded to its catalogued capacity. In all 36 1-2 tons were transported 756 miles on 2247 gallons of gasoline and 148 gallons of lubricating oil.

One error was made in the laying out of the route that greatly affects the final results. For two days the cars were driven through a territory where the roads were in terrible shape, and the conditions were anything but those for which the commercial car is designed. No one would ever consider the use of a commercial car in a country where the roads were impassable, and during these two days all of the larger vehicles in the run were subjected to strains that never would be encountered in any regular service in which a motor vehicle would be practicable. Had it not been for the severe conditions encountered during these two days, a much better fuel and oil economy would have been shown by the heavier vehicles.



Federal, No. 32, winner in Class 5K, climbing Gulch Hill, near Battle Creek

Kelly, No. 17, driven by Withgott, which won in Class 8K, performed well throughout the run

Many gallons of fuel and oil were consumed by those vehicles during the hours that their engines were being strained and raced while pulling each other out of the deep sandy places that allowed the axles to rest on the roadbed.

As for the weaknesses in design and construction that the run brought out in the various contesting vehicles, there were but few, and these for the most part of small importance. The test, however, was a severe one, and those vehicles that did have weak points had them very plainly shown up. It was an excellent means of showing the maker where the weak points lay.

Another important feature was the excessive wear on some of the tire equipment, some of the vehicles having to make several changes, while others of the same weight made no changes and still managed to keep their tires in good shape. The following facts were brought out: Where a car is to be used on country roads where there are ruts to contend with, the tread of the wheels should be standard and the wheels shod with single and not dual tires.

In cases where the tread was wider than standard, it was necessary to drive with the wheels on one side of the car in a rut, while the other wheel would be breaking down the crest on the outside of the other rut, thereby causing excessive power consumption and excessive wear on the one tire and perhaps on both. If dual tires are fitted, and the tread is standard, then both outside tires generally are breaking down the crest of the ruts on either side, and rapid wearing away of the rubber takes place.

Dorris Wins Missouri Run

St. Louis, Aug. 21—A Dorris car, driven by J. E. Baker, won first place in the touring car class in the four-day reliability run from St. Louis to Kansas City and return, which began Aug. 14 and finished Aug. 17, under the auspices of the St. Louis Automobile Manufacturers' and Dealers' Association. Incidentally the Dorris also carried off the special cup offered by the St. Louis Motor Accessories Association for the car, regardless of class, to finish with the highest score.

A protest was filed against the Ford, which was awarded first honors in the runabout class, on the ground that it did not carry stock equipment. The protest was sustained, and the final award made to the Flanders, which had been penalized two points.

The route followed going to Kansas City was what is known as the Northern Highway, and the return trip was made by way of the Central route, which has just been adopted as the official State Highway. The Inter-State was penalized 50 points for being late at a control, having lost the route. The Parry was penalized for a motor stop due to water getting into the carbureter at a deep ford. The Cadillac was disqualified because the driver misunderstood the rules and worked on his car at noon stop. The Ohio withdrew because of a series of small mishaps, after making a perfect road score for two days. The Hudson was penalized for losing the road, and the Marmon drove 50 miles out of its way and was penalized. Summary:

Car.	Road Score.	Technical Score.
	TOURING CARS.	
Dorris	Perfect	Perfect
Marmon	3	Perfect
Mitchell	9	Perfect
Parry	7	5
Interstate	56	8
Hudson	12	53
Buick	53	36
Ohio	Withdrawn	
Cadillac	Disqualified	
	ROADSTERS.	
Ford No. 6	Perfect	Protested
Flanders No. 12	Perfect	2
Ford No. 5	35	Perfect
Flanders No. 11	96	2

Blanks Out for Fairmount Park Race

Philadelphia, Aug. 21—The Quaker City Motor Club on Friday afternoon issued entry blanks for the Fairmount Park 200-mile road race to be held over the 8-mile West Park course at noon on Saturday, October 7.

The placing of the management of this annual classic in the hands of the Quaker City Motor Club ends a contest that has been waging off and on for a period of several months between the Quaker City Motor Club, Mayor Reyburn and the Philadelphia Automobile Trades Association, the latter organization, composed of dealers in gasoline pleasure cars, having some time ago put in a bid for the honor of conducting it.

As in last year's race, cars will be classified in four divisions, 3-C, 231 to 300 cubic inches piston displacement; 4-C, 301 to 450; 5-C, 451 to 600; 6-C, 601 to 750; cars in each of the divisions to compete for division prizes of $1,000, with a grand prize of $2,500 for the car making the best time.

The entry list is limited to 30 cars.

Jerseymen Moving for Reciprocity

Spring Lake, N. J., Aug. 21—That the residents of this State are feeling the effects of the restrictive legislation that is keeping the motorists of adjacent commonwealths away was demonstrated at a meeting held here last Saturday, and which was called at the instance of T. Frank Appleby, of the Ocean Boulevard Commission. Many prominent men from all parts of the State were present, and although several items were mentioned in the call for the meeting, it was manifest that the subject nearest the hearts of all was that which had to do with the passage of a law that will insure reciprocal treatment to the auto-

To Tear Down Signs

Ugly and puzzling defacements of warning and distance marks on the highways of New York may be destroyed by anyone after Sept. 1 and signs displayed upon highways that are not specifically permitted by the owners of private property may also fall under the axe of anyone who pleases to destroy them. The A. C. A. proposes to make September 1 the day for such destruction.

"CLEAN-UP DAY" is being strongly advocated by the Good Roads Committee of the Automobile Club of America, meaning that on September 1 when the new law prohibiting the defacement of sign posts, milestones and danger signals to automobilists goes into effect that owners of automobiles shall make it a point to destroy all such defacements.

The accompanying illustrations show how the meaning of a warning to automobilists may be fogged with extraneous matter and the law prescribes that unauthorized signs may be destroyed by anyone.

The section of the law relied upon by the club as its author-

This is the kind of thing that automobilists are asked to put an end to on and after Sept. 1

mobilists of other States granting similar privileges to motorists of this State.

After a long debate a resolution introduced by J. H. Wood, president of the Associated Automobile Clubs of New Jersey, was finally adopted calling upon the Legislature to pass a reciprocity law at its next session, at the same time providing against any possible reduction of the revenue by urging that the law be so framed as "to show an increase" in receipts.

At the opening of the meeting Mr. Appleby, who is Mayor of Asbury Park, admitted that the motorists were a big factor at all the shore resorts, and that everything possible should be done to attract them. Other speakers who advocated remedial legislation were H. A. Bonnell, general manager of the Automobile Board of Trade; Frederick W. Kelsey and J. C. Anthony. The resolutions as finally adopted read as follows:

"Resolved, That a law be enacted with regard to the use of automobiles within the State which will grant the same rights and privileges to the owners and drivers of machines from other States that are accorded the citizens of New Jersey, in the States from which said owners and drivers hold their licenses; and be it further,

"Resolved, That it is the sense of this meeting that the system of licensing automobile in New Jersey be adjusted so as to show an increase of revenue."

The meeting also passed a resolution favoring the enactment at the next session of the Legislature of a law which shall place the maintenance of "through roads under the direct supervision of the State Road Department." At present the various counties and towns are taking care of their respective roads with indifferent success.

A representative delegation of prominent automobilists waited upon Governor Woodrow Wilson, of New Jersey, on Tuesday, seeking his aid to alleviate the peculiar legal situation in Jersey. The party was headed by H. A. Bonnell, general manager of the Automobile Board of Trade, and included J. R. Wood, president of the Associated Clubs; George Blakeslee, Senator Edge and several other leaders in the fight.

The main point discussed was the abrogation of the nauseous Power of Attorney clause and in emphasizing this phase of the matter, Mr. Bonnell on behalf of the delegation submitted to the Governor a copy of last week's issue of THE AUTOMOBILE containing an extended article on the Jersey Chinese Wall which paid particular attention to the objectionable clause.

Governor Wilson accepted the article and assured the committee that he would give it due attention.

ity for undertaking the campaign was passed by the recent legislature and is as follows:

"A person who willfully or maliciously displaces, removes, injures or destroys a mile-board, mile-stone, danger sign or signal, or guide sign or post, or any inscription thereon, lawfully within a public highway; or who, in any manner paints, puts or affixes any business or commercial advertisement on or to any stone, tree, fence, stump, pole, building or other structure, which is the property of another, without first obtaining the written consent of such owner thereof, or who in any manner paints, puts or affixes such an advertisement on or to any stone, tree, fence, stump, pole, mile-board, mile-stone, danger-sign, danger-signal, guide-sign guide-post, billboard, building or other structure within the limits of a public highway *is guilty of a misdemeanor.** *Any advertisement in or upon a public highway in violation of the provisions of this subdivision may be taken down, removed or destroyed by any one.*

"This act shall take effect September 1, 1911."

*A misdemeanor is punishable by a fine up to $500 or one year in jail, or both, at the discretion of the Court.

Another instance of the defacement of roadside trees due to pernicious advertising methods

Jersey Farmer Helps

This being a true incident of an actual experience suffered by an interstate tourist who met with delay and tire trouble and ran short of gasoline. The following story tells just how the Jerseyman rose to the occasion and combined the joys of a kindly act well performed with the chance to make a little hay while the sun did not shine.

WILMINGTON, DEL., Aug. 21—An interesting story is being told here—and it is true, too—which has got what is commonly known as "Jersey extortion" beat a mile, and it may be a coincidence that it all happened in Jersey.

A few weeks ago George A. Elliott, a prominent local attorney and churchman, went to New York to sail for Europe, with his family, leaving Wilmington the day before he was to sail. After reaching New York he decided to take his touring car abroad and accordingly telephoned to his chauffeur, who was at his house, here, to bring the car to New York and to deliver it by 10 o'clock that night at the Waldorf-Astoria, where the Elliotts were temporarily stopping.

All went well until Trenton was reached, when he had a blow-out. This caused a delay, but was not nearly as serious as the next mishap, when both tubes of one of the tires exploded, after the machine had proceeded a short distance above Trenton.

Nightfall was coming on and just as the machine entered a heavily wooded road the car stopped short and an examination showed that the gasoline was exhausted.

After waiting until about 11 o'clock, and with no hope of any other solution of the problem, the chauffeur set out on foot for the next town, about 2 miles distant, but he was unable to get any gasoline. He was informed, however, that 3 miles further on there was a farmer who had a gasoline engine, and that he might be willing to sell a sufficient quantity.

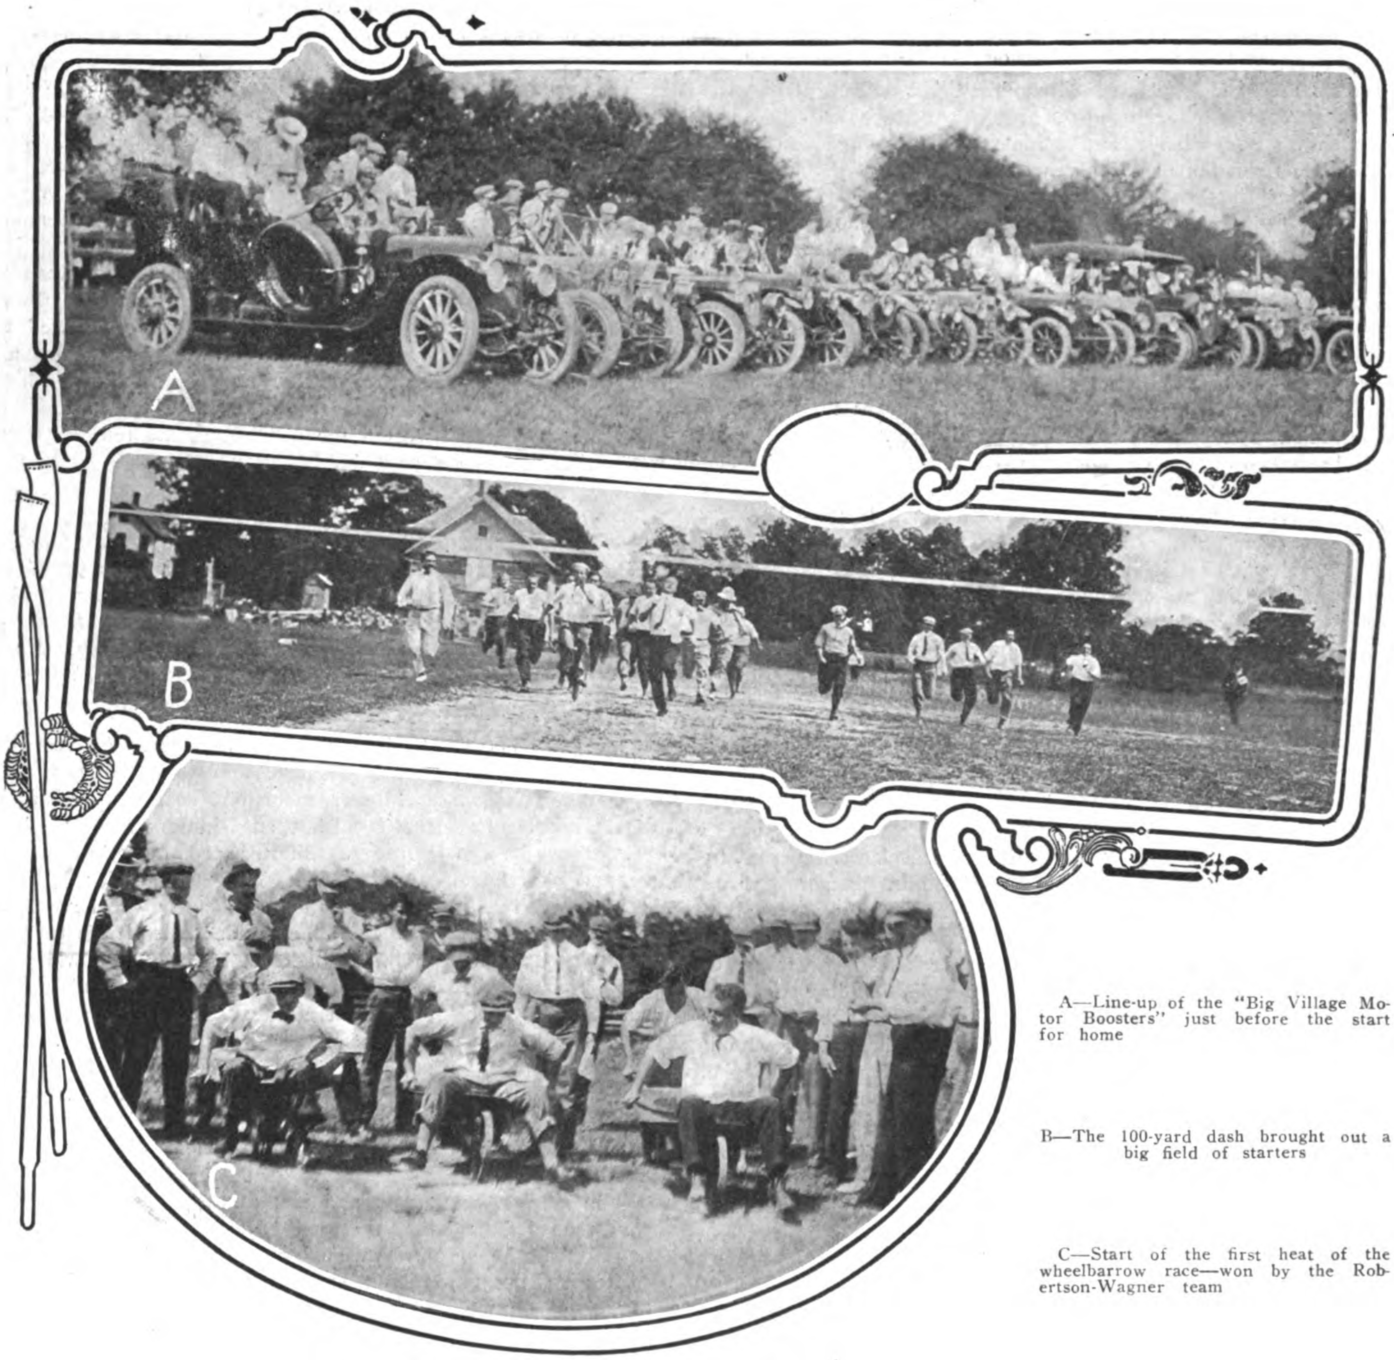
There was nothing else to do and the chauffeur "hoofed it" to the abode of the aforesaid farmer, whom he finally succeeded in arousing from his slumbers. After the situation was made clear to the sleepy farmer, the latter agreed to let the chauffeur have three gallons of gasoline, and with the gasoline and chauffeur he started in his wagon in the direction of the belated machine, which was reached in due time.

Before the farmer would permit the gasoline to be taken out of his wagon he demanded settlement. There were three gallons and he was asked what he was going to charge for them. "Nine dollars a gallon," was his reply.

"Why you are joking," said the chauffeur.

"No, I'm not," the farmer replied. "You will have to pay me $27 before that gasoline leaves my wagon. You don't suppose I'm going to get out of my bed and haul oil five miles for nothing. My price is $9 a gallon, and nothing less."

It cost Mr. Elliott just $185 to get his car driven over from Wilmington to New York.



A—Line-up of the "Big Village Motor Boosters" just before the start for home

B—The 100-yard dash brought out a big field of starters

C—Start of the first heat of the wheelbarrow race—won by the Robertson-Wagner team

Motor Boosters' Picnic

Over 100 men connected wth the New York automobile industry in one way or another attended the first annual outing of the organization known as the Big Village Motor Boosters. The affair was held at Smithtown, L. I., and a long semi-athletic program was decided and everybody had a splendid time. The baseball game was a feature of the outing.

SOMETHING over 100 members of New York City's automobile industry answered the call issued by the Big Village Motor Boosters for its first annual outing Wednesday, August 16, at Smithtown, L. I. The bulk of the boosters made the 49-mile run by automobile, reaching Riverside in time for breakfast. The first number on the program after breakfast had been allowed to settle was a baseball game in which everybody but the cripples took part. It is recorded that there were four shortstops on each side. The final score after five innings was 83 to 47, Captain George Robertson's team being on the long end. Horace A. Bonnell, General Manager of the Automobile Board of Trade, acted as umpire of play and escaped practically unscathed.

James E. Sullivan, recently named as a member of the new boxing commission, was to have acted as referee; but owing to the injuries he sustained in a train wreck a few days ago, he was excused and Mr. Bonnell subbed on the job.

The 100-yard dash developed some fast announced time, the time being much faster than anything in the race, as it was discovered afterward that the course was twenty yards short. There was a long program decided embracing every known form of contest and a few that were specially invented for the occasion. The automobile obstacle race, during which the cars were required to make a serpentine course around a series of barrels, was won by a Corbin (W. E. Carney) defeating the bigger and heavier cars around the sharp turns.

There were swimming races and just plain bathing and lots of other amusement for the members.

The whole affair was most enjoyable and throughout there was not an unpleasant incident. The spirit of good fellowship pervaded. At dinner, which wound up the day of pleasure, over

D—Fur flew when the "Mutts" and "Jeffs" met on the baseball field

E—Somebody lost a diamond on the ball field, and a systematic search found it

F—Many of the Boosters found time for a dip in Long Island Sound

100 sat down together. Mrs. Fred J. Wagner provided lunches for the picknickers during the day.

The boosters plan some other variety of function during the Fall and a smoker shortly after the conclusion of the metropolitan show season.

Score Enter Glidden Tour

Despite the fact that entry blanks for the Glidden Tour of 1911 have been issued only about a week, a score of entries have already been received and more are being received every day. The start of the tour is scheduled to take place at New York, October 15, and the finish will be at Jacksonville, Fla., October 25. The course over which the automobiles will travel will be via Atlanta.

The final clause in the entry blank is causing much interest and not a little comment. It reads as follows: "Inasmuch as the National Tour is a good roads and tourists' tour, without technical examination or technical penalties, it is open to any owner of a bona-fide touring car or runabout and the Stock Registration Requirement of the rules is hereby waived."

The contestants will run in teams of three, not necessarily of the same make or year, and the award will be made to the city represented by the team accumulating the least number of demerits.

So far the entry list comprises the following: 1912 Flanders, C. E. Winn, Atlanta; 1912 White, J. S. Cohen, Atlanta; 1910 Chalmers, J. H. Marsteller, Roanoke, Va.; Oldsmobile, Dr. W. N. Stinson, Jacksonville, Fla.; Cadillac, Claude N. Nolan, Jacksonville, Fla.; Garford, R. P. Hooper, Philadelphia; 1912 Maxwell, U. S. Motor Co., New York; 1912 Maxwell, U. S. Motor Co., New York; 1912 Maxwell, U. S. Motor Co., New York; 1911 Pierce-Arrow, E. P. Ansley, Atlanta; 1912 Stevens-Duryea, C. H. Johnson, Atlanta; 1911 Marmon, H. M. Grant, Atlanta; 1912 White, J. S. Cohen, Atlanta; 1911 Cole, H. B. Race, Jacksonville; 1911 Cadillac, O. S. Albritton, Jacksonville; 1912 Cadillac, W. J. Hillman, Live Oak, Fla.; 1912 Cunningham, A. H. Whiting, New York; 1912 Reo, Ray M. Owen, New York; 1912 Reo, Ray M. Owen, New York; 1910 Knox, W. C. Aycock, Moultrie, Ga.

NEWS OF THE WEEK CONDENSED

RAMBLER SALESMEN GATHERED AT THE KENOSHA, WIS., FACTORY FOR THE ANNUAL CONVENTION

Top Row—G. M. Berry, M. Mattson, C. D. Hagerty, A. L. Stapleton, G. R. Sutherland, Al. Reeke, E. J. Wall, A. R. Rockwell, C. S. Culp, B. F. Spencer, O. Murphy, G. H. Cox, H. F. Lantz, G. Braithwaite. Second Row—W. F. Portwine, J. M. Gaffney, R. S. Bennett, C. Sklarek; C. A. Baker, J. K. Bond, F. E. Devlin, Gilbert Williams; F. C. Mock, J. O. McDonald, J. A. Rose, W. C. Burbank, E. S. Jordan, J. P. Zens, R. Jardine. Third Row—O. G. Formhals, E. G. Soward, H. H. Maddock, F. W. Rosche, T. D. Cobbs, Jr., G. B. Owens, H. E. Tanner, F. C. Bacon, W. S. Simonds, L. A. Poundstone, W. H. Knight, T. B. Long, I. J. Kinnett, L. E. Rood, R. C. Chase, C. D. Dunham, C. M. LeRoux, G. D. Racine, Z. C. Elkins, H. G. Musgrave, H. P. Thompson. Fourth Row—J. W. DeCou, M. E. Lebon, E. E. Herring, W. E. Wissler, G. C. Norwood, S. S. Jenkins, I. R. Campbell, C. T. Jeffery, E. J. Leach. W. G. Schultz, H. M. McEachren, P. J. Keating, C. O. Hart, G. A. Ruckert, P. D. Carman, L. P. Kilbourne, G. N. Bliss.

NEWARK, N. J.—Forty applications were acted upon at the August meeting of the trustees of the New Jersey Automobile and Motor Club last Tuesday, bringing the membership total close to the 2,500 mark. *The Club Bugle*, the official organ, made its first appearance last week.

PITTSBURGH—The newly organized Chamber of Commerce at Sharon, Pa., through its chairman, H. H. Cohen, announces that Sharon has secured a big automobile factory on which work will be started within sixty days. The plant may afford employment to 2,000 hands and the company, which is now being organized, it is stated, will have a capital of $250,000.

COLUMBUS, O.—The announcement is made that the Eastern Automobile Company, recently incorporated with a capital of $20,000, has taken over the garage and repair shop formerly operated by the L. & E. Garage & Sales Company at 60-62 East Spring street, Columbus, Ohio. J. Goldstein is president; J. E. Leacy, secretary and F. F. Cain, general manager.

PITTSBURGH—Edward M. Bigelow, of Pittsburgh, State Road Commissioner of Pennsylvania, recently appointed by Governor John K. Tener, announces that work will be started shortly on a 50-mile thoroughfare to extend from Gettysburg and by the historic battlefield to the Pennsylvania State line. He plans to have the road entirely finished by the time the grand reunion is held in Gettysburg.

TOLEDO, O.—The new club house of the Willys-Overland employees, located at Bay Shore, Toledo, is furnishing much diversion this summer. One of the latest functions was a dance given by the girls from the top and trim departments. The Overland band furnished music for the dancers. About forty young women employed at the plant attended.

DES MOINES—The Des Moines Automobile Association will hold an automobile show in connection with the Iowa State Fair, which is to be held in the last week in August at the State Fair Grounds. Practically all the dealers in the city have reserved space, and the affair will be second in importance only to the annual Winter Automobile Show. A feature of the show is to be a floral parade, which will be the first of the kind ever held in Des Moines.

RACINE, WIS.—George Williams, superintendent of the motor department of the J. I. Case Threshing Machine Co., Racine, Wis., whose resignation was announced a short time ago, will on Sept. 1 become factory manager of the King Motor Co. of Detroit, in which he holds an interest. On leaving Racine Mr. Williams was tendered a banquet by the foremen and employees and was made the recipient of many valuable gifts, including a watch suitably inscribed, a set of cuff links and a studded watch charm.

PITTSBURGH—The American Rubber & Fabric Company gave a demonstration of its puncture-proof tire on Grant street last week. A car equipped with its tires and heavily laden was run over a plank from which protruded 100 sharpened spikes extending out from one to two inches. Although the spikes penetrated the rubber shoe of the tire they did not puncture the fabric lining. The American Company has secured a location at Jeannette, Pa., on the main line of the P. R. R.

HARTFORD, WIS.—Work on the addition to the works of the Kissel Motor Car Co. of Hartford, Wis., has been started. The building will have dimensions of 107 x 200 feet and will be three stories high, with 12 and 14 foot ceilings, of solid brick construction. Contracts have also been awarded for the construction of an addition to the machine shop, to be 50 x 112 feet in size. It is hoped to have both structures ready by Nov. 15 or Dec. 1, as the big Kissel works are now cramped for room and the enlargement of the output for 1912 makes more manufacturing space essential.

GRAND RAPIDS, MICH.—W. R. Link and Fred Hicks are promoters for a new industry, the purpose of which will be the refinishing of automobiles. Mr. Hicks at present is connected with the Adams & Hart company in the capacity of contractor for the refinishing business and he is an experienced workman. He will manage the factory end of the business, and Mr. Link, who is quite well known in the city, will have charge of the offices and publicity branch. The company will be incorporated for about $30,000, it is expected, and a new two-story building will be erected for its accommodation.

ST. LOUIS—The Central Route, which follows in a general way the old Boone's Lick road and the Santa Fé trail, has been designated the official Missouri State Highway by the State Board of Agriculture, on condition that satisfactory progress is indicated in the improvement of the roads within the next few weeks. Governor Hadley and members of the Automobile Club of St. Louis recently made a motor car trip over the road selected in an effort to choose a State highway. The road is to be opened with appropriate ceremonies, including an automobile tour, about Oct. 15, according to present plans.

Irvington-on-Hudson—The New York branch of the Locomobile Company of America has just delivered a combination chemical and hose automobile of 40 horsepower to the village of Irvington-on-Hudson.

New York—Byrne, Kingston & Co., makers of the Kingston carbureter, have established a metropolitan branch office in the Buick building, 1733 Broadway. The former headquarters of the concern were at 1650 Broadway.

Los Angeles—Brown-Symonds Co., 1140 S. Olive street, have taken on the agency for the Stutz car, built by the Ideal Motor Car Co., Indianapolis, Indiana. They expect to enter one of these cars in the Santa Monica road race.

Pittsburgh—J. Eugene Beck, with offices in the Jenkins Arcade building, has secured the agency of the Midland line of automobiles manufactured by the Midland Automobile Company of Moline, Ill. It will have four models, including a two-passenger runabout of 40 horsepower and a seven-passenger 60 horsepower.

Brooklyn—E. J. Montigny, owner of the Plaza Garage, Bedford avenue, near Bergen street, who was formerly agent for the Abbott-Detroit, has closed a contract with the Ideal Motor Car Co., of Indianapolis, Indiana, for the sale of Stutz cars in Brooklyn and Long Island. He expects to receive his first demonstrating car the early part of September.

Buffalo—The firm of Baker Bros., Geneva, N. Y., and E. H. Green, Cole 30-40 distributors, have consolidated under the firm name of Baker Bros. Motor Car Company. The firm have taken quarters at 846 Main street, Buffalo. Baker Bros. will continue to sell Cole cars in Geneva. This branch being under the direction of Clarence Baker, E. H. Baker and E. H. Green will handle the Buffalo business.

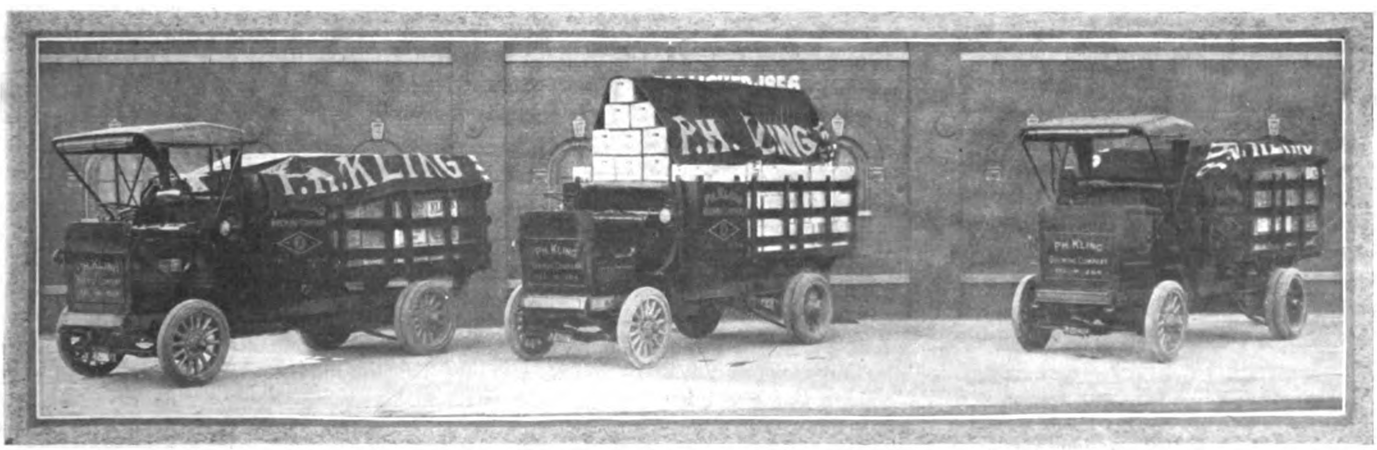
Seabrook, N. H.—This town possesses the star motorists' trap. An automobilist who pleads guilty is "let off" with a $5 fine, to which is incidentally added "costs" of $1 apiece for each constable who is on the job (there are usually three or four besides the complainant, who gets $1.62 for his extra exertions), $1.38 to the judge who hears the case, $1 to the State secretary, $5 to the State treasurer. Steep as is this total, it is usually cheaper than pleading not guilty, for in this instance the luckless motorist, if found guilty, is mulcted to the tune of $25, besides the expense of traveling to New Hampshire to attend court.

Washington, D. C.—A bill to establish a Federal Highways Commission, whose duties it shall be to urge the co-operation and joint action of the several States with the Federal Government in the construction, improvement, and maintenance of permanent and durable highways throughout the United States, prescribe such rules of agreement in connection with their use as will insure uniform and equitable highway regulations, and issue Federal licenses governing interstate automobile travel or commerce, was introduced by Representative Linthicum August 16 and was referred to the Committee on Interstate and Foreign Commerce and ordered to be printed.

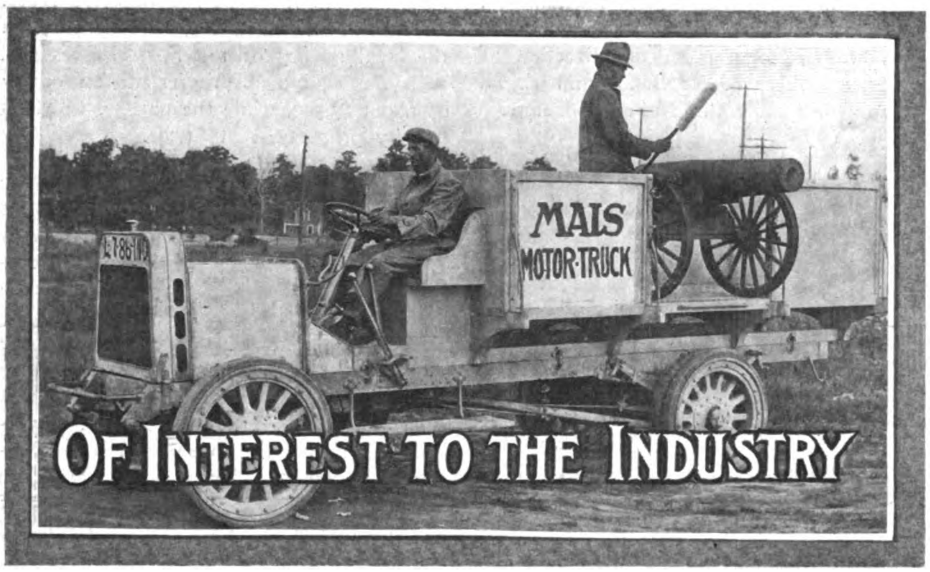
Wilmington, Del.—A week's successful service, performing with satisfaction the work of four horses and two wagons, has convinced the Police Department heads of Wilmington that they made no mistake in adopting a motor patrol wagon and relegating the horse-drawn vehicles. Basing his calculations on the experience of the past week and his knowledge of automobiles, Chief of Police Black believes the automobile now in use here, a six-cylinder 40 horsepower Pierce-Arrow, will pay for itself and the garage in which it is housed and which was built by the city expressly for it, within the next two or three years. The machine, which was bought through the local agency of the Foss-Hughes Co., with the equipment, represents an outlay of about $3,500, while the garage, which is on city property, cost $1,000.

Baltimore, Md.—Sign posting on the road between Baltimore and Annapolis has been completed by the Automobile Club of Maryland under the supervision of Secretary H. M. Luzius. This is in line with the pledge made at a recent meeting of the club to complete as soon as possible the posting of all roads leading into Baltimore within a radius of ten miles. Work will soon be started on the Frederick, Washington, Hagerstown and York roads. Secretary Luzius and his workers made the trip over the State highway, eight miles of which he says is in excellently improved condition, having been newly laid. Through the courtesy of the Mar-Del Mobile Company, local representatives, a Packard delivery wagon was used for carrying the signs, post tools, workers, etc., while Secretary Luzius used his Cadillac car in directing the work.

Fond du Lac, Wis.—A résumé of conditions in the motor car field at Fond du Lac, Wis., discloses facts that are regarded as typical of similar cities in Wisconsin. Local sales agents sold approximately 165 cars from Jan. 1 to Aug. 15. Of this number 39 cars were purchased by residents of Fond du Lac, about fifty were sold to farmers and the remainder in a small territory surrounding Fond du Lac. The average price of the cars was $1,250, which is about 20 per cent. lower than the average for the preceding year, and indicates the trend of the trade at this time. There is also a change of the base of the market. Formerly the agent sought city buyers and did not attempt to interest the farmers. To-day the farmers are the sought and the seeking and are taking the larger percentage of the total sales. The city trade practically takes care of itself and requires no particular effort on the part of the agent. Fond du Lac is a city of upwards of 17,000 population.



Three-load Universal motor trucks recently sold to a big brewing firm in Detroit



INDIANAPOLIS, IND.—Will H. Brown, president of the Mais Motor Truck Company, came to the rescue of charity workers here with an original method of getting crowds out to a fair for the benefit of a fresh air mission. Mr. Brown had a cannon built and mounted on a truck. Advertising cards telling about the fair were loaded in the cannon and by a strong spring trigger attachment, they were shot forth along the streets into the crowds as the truck was driven all over the city. A bugler rode on the seat with the driver and gave a "military" atmosphere to the "stunt."

NEW YORK—A. O'Donnell has been promoted manager of the New York office of the Booth Demountable Rim Company.

SAN FRANCISCO—The Abbott-Detroit "Bulldog" has now covered 31,000 miles in its contemplated journey of 100,000 miles.

LOS ANGELES—The Chanslor and Lyon Co. has announced that it has taken the agency for the Pacific Coast of the Kelly-Racine tire.

DETROIT—The Packard Motor Car Company announces that recently the company shipped thirty cars and ten trucks from the factory.

ST. LOUIS—The agency for St. Louis for Cook's Auto Transmission Lubricant has been placed with the Marine Supply Co.

GALION, O.—W. E. Dunston has been appointed general manager of the Ditwiler Mfg. Co., manufacturing the Ditwiler steering gear and other products.

CLEVELAND—W. S. Eaton, formerly superintendent for Jas. Cunningham, Son & Co., Rochester, N. Y., has accepted a position with the White Co., Cleveland, O.

BERNARDSVILLE, N. J.—Bernardsville Fire Co. has appointed a committee to look after the purchasing of a motor-driven pump automobile with 1,000 feet of hose.

OCONTO, WIS.—Frank Smith and H. N. Bradley have formed a partnership and will build a garage and repair shop on Superior street.

HUDSON, WIS.—The Hudson Garage Co. has been incorporated and chartered with an authorized capital of $10,000. The promoters are Emil E. Meyer, W. M. Grant and Chrs. Nickelby.

NEW YORK—After a trip of 2,536 miles the touring Commer truck has returned to New York. The company announces that the average gasoline consumption was one gallon to 7.1 miles.

PITTSBURGH, PA.—The Vulcan Motor Supply Company has been organized by Frank H. Seely, Jr., J. G. Tite and H. T. Slater at Altoona, Pa., and will do a general automobile business.

HARTFORD, CONN.—The C. W. Kelsey Mfg. Co., makers of the Motorette, announce that this name has been duly registered as a trade mark under Patent Office Trade Mark registration 52,764.

BOSTON, MASS.—The Commer truck is the latest to secure an agency in Boston, having been taken on by the Dodge Motor Vehicle Company, that also handles the Pope-Hartford and the Waverley electric.

CLEVELAND—W. F. Melhuish, formerly sales manager of the Croxton-Keeton Company, has been appointed manager of the sales department of the White taxicab.

NEW YORK—C. A. Mezger, Inc., announces that the prices of Soot Proof spark plugs will probably be reduced this fall. If such action is taken, the company states that sales after Sept. 1 will be protected.

SAN FRANCISCO—The Pioneer Automobile Company has secured the agency in Northern California for the Commer truck and Guy Vaughan car, representing Wyckoff, Church & Partridge, Inc., of New York.

BELOIT, WIS.—J. H. Saris, agent for the Ford in Beloit and surrounding territory, has leased the former Broadway Skating Rink building and will remodel it for garage and salesroom purposes. The building is 130 by 49 feet in size.

SHEBOYGAN, WIS.—The Erie Garage, North Ninth street, owned and conducted by H. E. Smith, has been purchased by Harry Black and I. E. Clarenbach. Extensive improvements will be made. The Erie Garage was the first in Sheboygan.

PITTSBURGH—The Kittanning Motor & Transfer Company is a new concern at Kittanning, the capital of the coke region, formed by G. H. Burns, J. S. Claypool, Roy M. Cox, D. L. Schaffer and D. E. Aceland of that place. The company's capital is $5,000.

PITTSBURGH—The Bessemer Motor Truck Company has been formed at Grove City, Pa., by I. M. Louis, A. M. Allen, L. M. Monroe, J. E. Marshall, E. J. Fithian and W. H. Shellits of that place. It will have a large garage and several important agencies.

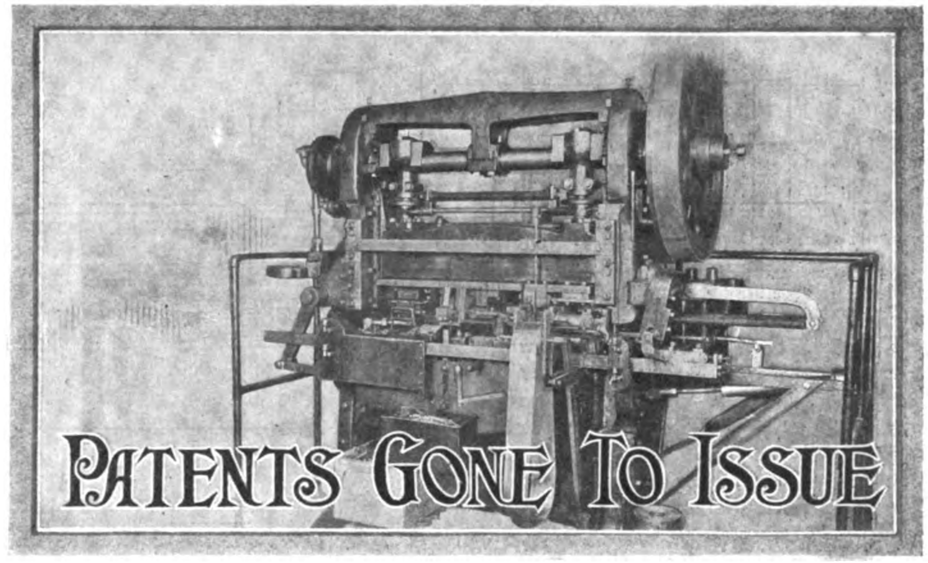
MILWAUKEE, WIS.—The Kopmeier Motor Car Co., 375-389 Summitt avenue, Milwaukee, Wis., has closed a contract for exclusive representation in the State of Wisconsin for three years of the Fiat car. The Kopmeier company is distributor of the Chalmers and Detroit Electric lines.

ST. LOUIS—The Brooks-Latta Company, which now has an experimental plant at 4255 Fairfax avenue, has secured an option on a lot with a frontage of 200 feet at Sullivan and Lambdin avenues, on which it is planned to build in the near future a factory for the manufacture of motor cars and delivery wagons.

NASHVILLE, TENN.—The Hager Elliott Engineering Company has opened a garage in connection with its large machine and repair shops on McGavock street. The new building has 24,000 square feet of floor surface and is the home of the Peerless, Velie, Empire and Paige-Detroit.

OSHKOSH, WIS.—The Crane Taxicab Co.'s building at Fifth and Wisconsin streets was badly damaged by a wind and rain storm. Preparations had been made for a large addition, and the excavations weakened one of the side walls. A new structure will now be erected on the same site.

TOLEDO, O.—The new home of the Roberts Toledo Automobile Company is rapidly nearing completion and will be ready for occupancy early in the fall. It is located at the corner of Madison and Eleventh streets, Toledo, and will face sixty feet on Automobile row. The first floor will be used as a display and salesroom and the second floor for repairs. A modern freight elevator will be installed.



WORM-DRIVE AND COMPENSATING GEAR—This gearset consists of a bevel gearing system driven by means of a gear and worm.

3. Fig. 1 shows the combination of a pair of aligned axle sections A A, bevel gears B B secured to the inner ends of these sections, and a worm gear G G mounted co-axially with respect to these sections and containing a spider frame S. One or more journal pins extend radially in the spider frame, each pin having a key slot in its outer end, with keys in them and extending into corresponding slots in the worm gear. A planetary pinion journaled on each pin meshes with the gears on the respective section of the axle shaft, a pair of housing sections H H encloses gears and pinions and turns with the spider. The housing sections are journaled on the gear hubs. A gear casing surrounds the axle sections, enclosing also the worm-gear and the housing sections. A worm W is journaled in the gear casing and meshes with the worm gear G G. Roller bearings placed between gear casing and housing sections hold the latter in position.

No. 999,876—to David E. Ross, Brookston, Ind., assignor to the Ross Gear & Tool Co., La Fayette, Ind.; granted August 8, 1911; filed December 16, 1908.

NUT LOCK—Being a specially constructed device, consisting of the elements described as follows.

This patent relates to the combination of a lock with a nut and bolt and a washer provided with a relatively thin portion having parallel grooves extending from its outer periphery. A central upstanding boss having vertically extending passages is provided, the passages communicating with the grooves referred to, which are parallel with the bolt opening in the nut. A locking pin has legs adapted to be forced along the grooves, which abut against a rear arched wall at the upper end of the passages in the boss, whereby the legs are deflected downwardly through the vertically extending passages in the boss. The bight portion of the locking pin is so bent as to engage the adjacent sides of the nut.

No. 999,842—to Carl Emil Nielson, Madera, Mexico; granted August 8, 1911; filed July 30, 1910.

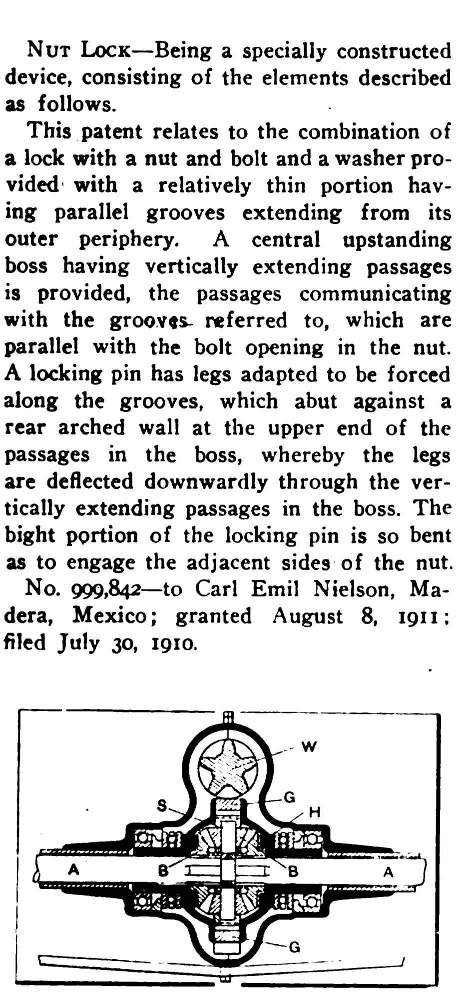


Fig. 1—The Ross Worm Drive and Compensating Gearset

SAND DISTRIBUTING VEHICLE—A construction intended to carry and distribute sand or like material.

1. The patent refers to a vehicle with a hopper mounted on the same and two feed-wheels charged from the hopper with the material. The wheels are connected by a flexible cross member. On each feedwheel shaft is mounted a main friction wheel engaging an auxiliary friction wheel. To an oscillatory shaft are journaled a pair of spring-urged intermediate friction wheels, one of these wheels being adapted to engage one of the main wheels and the other intermediate wheel to engage with the auxiliary friction wheel. A driving friction wheel is provided which engages with one intermediate wheel while the other intermediate wheel engages with the auxiliary friction wheel.

1,000,004—to Werner Huber, Sihlbrugg, Switzerland; granted August 8, 1911; filed August 24, 1910.

ADJUSTABLE ELECTRIC LAMP—This is a construction in which the lamp may be adjusted relatively to the reflector of the headlight.

1. The headlight shown in Fig. 2 comprises a lamp with closed back B, a parabolic reflector R therein and a short flange F integral with it. The non-rotatable sleeve S extends through the flange and may be moved inwardly or outwardly through the office of an axial screw shaft A actuated by an adjusting nut N, whereby the position of the plug holding the source of light relatively to the lamp reflector is altered.

No. 999,860—to Ward S. Perry and Julius O. Eis, Chicago, Ill., assignors to Vesta Accumulator Co., Chicago, Ill.; granted August 8, 1911; filed November 15, 1909.

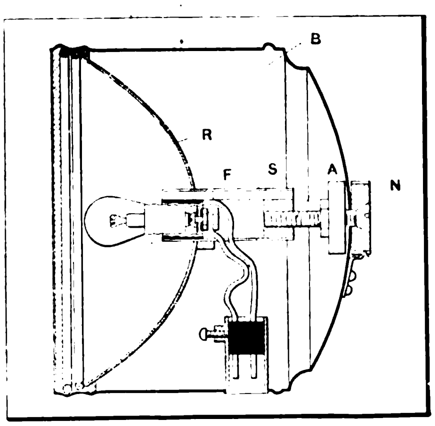

Fig. 2—Perry Electric Light with adjustable lamp socket

INTERNAL COMBUSTION ENGINE—This patent covers the combination of two opposed cylinders with an interposed crank-chamber and connections thereof to the cylinder spaces, the engine operating on the two-stroke cycle.
